*C. P., Ariz.*—The only satisfactory way to disinfect hives in which there has been foul brood is to immerse them in boiling water and keep them there for a few seconds. Some have advocated smearing the inside of the hive with kerosene, and then touching a match to it, and letting the fire char the inside out; but this blackens and disfigures the inside of the hive. For further particulars regarding foul brood, see the article under that head in our A B C book.

*C. R. B., O.*—Twenty-five colonies of bees at \$1.00 apiece is very low, and I do not see why it would not be a good bargain for you to take up with—that is, providing you have had experience, as you say you have. You will find very full particulars in regard to shipping bees under the head of "Moving Bees," in the A B C book, which you have just purchased. The frames or combs in the hives should be held securely in position by sticking up, if they are not already fast. It is best to remove the cover of the hive and tack mosquito-netting over the top, or, better yet, wire cloth. The entrance should be closed. The hives themselves should be set upon loose straw in the bottom of the car, with the frames running parallel with the rails of the track. If they are crosswise there is a liability of the combs breaking out when the car bumps against another.

*M. B., Texas.*—Referring to the short method of transferring, as given in our catalog and our A B C book, I would state that queen-cells, of course, will start in the old hive having the remnant of bees to take care of the brood. If you wish to prevent these from making any trouble at the last shaking out, in about eight days drum the bees out again, cut out the comb, and then destroy what cells may be built. These loose pieces of comb you can put on top of the colony that has been transferred and is in the new hive. When the brood hatches out, remove these pieces of comb and render them into wax; but it will do no harm, ordinarily, to let the cells be completed and hatch out young queens. At the end of three weeks, in this case, drum all the bees out; and if there are any young queens they will go into the new hive. Either the old queen and bees will kill the young queens or else one of the young queens will supersede the old queen. In either case the result will be that only one will be left, all the others being destroyed. When colonies are transferred from box hives, the probabilities are that the bees will be blacks or hybrids, and the young queens would not be very valuable.

It seemed very peculiar to Fred to address Alfaretta as Miss Buell, and to be addressed by her as

Mr. Anderson; and, though the familiar face was before him, they were, under the new reign of reason, strangers. Then her voice, her eyes, her general bearing, betokened a sensible young woman. Showing signs of fatigue, Fred persuaded her to retire again to the cabin, and rest, assuring her that the separation from her parents should be looked upon as a providential occurrence; for, had she never been separated from her parents in this strange way, the chances were that she never would have recovered. Now in a few weeks she could return, and surprise her people by the recovery from her terrible malady.

When Alfaretta had entered the cabin, Fred strolled down to the little grove of oaks, and there, an hour later, Dr. Hayden found him in deep thought.

"Fred," said the doctor, "I think I can divine your thoughts. Alfaretta sane is not the young lady she was to you. Remember, all the past must be a blank, and your acquaintance must be renewed from the present."

"Yes," replied Fred, "those were the very thoughts that were occupying my attention. When I thought myself well acquainted with Alfaretta I find that I must commence my acquaintance over again. She is so different that I hardly know how to act in her presence."

"I see," said the doctor. "In her evident desire to seek you, and to be near you, you have allowed your sentiments to get the best of you."

"Compelled, you mean," replied Fred; "who could withstand such loveliness, even though the subject were insane? and now that she is sane, I fear I am unworthy to approach her."

"Ah! well," said the doctor, as he moved toward the cabin, "young people are liable to build air-castles, and tenant them with fairies and angels; but I think you will find Alfaretta very human after all."

The days and weeks sped all too fast for Fred. He applied himself assiduously to the management of the bees; and had he been in any other place he would have avoided Alfaretta; but the narrow confines of the valley made that impossible.

The increase of the apiary was checked, and the energies of the apiary were being prepared

for a honey harvest. The doctor was much worried in getting his supplies; he spent much time with his signal colony, and he learned from the returning bees from day to day that there was danger outside. The disappearance of a girl and boy almost before their eyes led the people outside to use every means to solve the mystery. Even the Indians were abused, and threatened with removal to a reservation in the far south. But the mystery remained unsolved.

As Alfaretta became stronger she longingly looked over the cliffs to the south, and entreated the doctor to allow her to return to her home.

"Why, my dear," the doctor would say, "you are not strong enough to endure, the hardships of a horseback journey. When I think you can endure it you shall return."

In her tramps around the valley she became familiar with every portion of it. At first Gimp was her leading chaperon. She realized that she had followed Fred to the valley, and, in consequence, was very reserved toward him; but, being passionately fond of flowers, which passion had never left her, even while insane, and finding many new varieties, she would take them to the doctor for the name; and, though he knew the names, he would send her to Fred. In that way they were thrown much together, against their wills, and finally they were taking many twilight strolls together, or singing songs to the accompaniment of Fred's guitar, with evident pleasure.

"Why, Mr. Anderson," said she, one evening, "I find new beauties here every day."

"That has been my experience," replied Fred; "but there is one beauty you have not investigated yet; you should study the wonders of the bee-hive."

"I fear I have as much abhorrence of them as our colored friend Sam has," she replied.

"Well, you ought not to," said Fred; "for it was the bees that indirectly returned you to health again."

Alfaretta, after much hesitation, consented one day to be veiled and gloved, and then Fred posted her in a safe portion of the apiary, and himself and Gimp entertained their guest for an hour by manipulating the hives before her. From this time she became a constant visitor to the apiary, and, under Fred's kind directions, she soon learned to manipulate a hive herself; and with what pride she related the circumstance to the doctor!

"But didn't you get stung?" said the doctor.

"Why, yes—ha, ha!" she laughingly replied; "a little bee stung me on the finger, and at first I thought Fred was going to kiss the finger; but he changed his mind and stuck a lump of mud on it."

"How could he?" asked the doctor; "but then, mud is a more efficacious remedy for

stings than kisses. I guess Fred was sensible, after all."

So time sped rapidly along. The doctor seemed in no hurry to get rid of his patient. She had been in the valley nearly four months, and springtime had well advanced. One day, as they gathered for their noonday lunch, she

"THERE WAS AN UPLIFTING OF THE ENTIRE VALLEY."

returned from the hot sulphur springs in haste, and said, "Doctor, there is a peculiar phenomenon at the sulphur springs. The spring you call the little geyser has disappeared, and there is a boiling mass of black mud all around it."

"That is peculiar," said the doctor thoughtfully. "That spring has held the even tenor of its way ever since I have lived here. I don't understand such an ebullition. It will bear examination."

Then the doctor and Fred hastened to the springs.

"Surely," said the doctor, "she must be mistaken; there is no chance for mud around those rocks;" but the doctor changed his mind when he looked down upon the familiar place, and an exclamation escaped from the lips of both.

"See," said Fred, in alarm; "that rock on which we had our nucleus colonies has been undermined, and there it goes into the seething mass."

"Yes," said the doctor, "that pit is enlarging; there goes another section of rocks."

A puff of steam now belched from the center; and as the wind blew it toward them they were nearly stifled by sulphur fumes. Another large section of rock and earth sloughed off between them and the abyss, and, after a tremor, sank, and hot steaming mud came uppermost. Fred felt the rock under his feet, and found it hot.

"Doctor," said he, "what does all this mean? We are in danger."

"Oh! no, Fred; this is merely an ebullition of an old crater, and will soon subside."

"Don't flatter yourself too much upon that point, doctor; craters have more back of them than we can imagine. I propose that we seek safety while we may, with the precious lives we have here. There," said Fred, in alarm, "goes an area as large as a garden-patch. Dr. Hayden, this very spot upon which we stand is liable to melt away. Hasten, doctor; we must save Alfaretta."

The doctor was loath to go, but followed Fred, who ran speedily toward the cabin, shouting to Sam and Gimp as he ran. When at the cabin he tried to appear cool, and briefly explained the situation; and when the doctor came up it was decided that they take a few valuables and proceed to the upper terrace, near the entrance. The doctor, from his age and experience, viewed matters very coolly; and when Fred thought the very ground under them might sink at any moment the doctor seemed unconcerned, and was the last to leave the cabin. While they were hastening toward the elevator there was an unusual tremor of the whole valley, and the upheaval of mud was greater than ever. The entire lower end of the valley appeared like a steaming caldron. Every one of the little party was now thoroughly frightened, and, with various exclamations, rushed for the elevator. This frail home-

made apparatus would carry but two persons, and Alfaretta and Alamantapola were sent up first. While the rest were taking their turns under the doctor's directions there were more seismic manifestations. The surging hot mud was engulfing every thing. The doctor's cabin, recently so pleasant with life, had disappeared. The boiling mud became more violent, the fumes mere stifling. The doctor and Fred were the last to leave; and as Fred was stepping from the elevator there was another violent tremor, and the elevator tackling gave way, and the apparatus, with some rock from above, went crashing down. Fred came near falling with it; but the quick hand of Alfaretta saved him. But what a terrible view was before them! The whole of the beautiful valley was breaking up. The little party seemed spell-bound at the fearful scene before them. Fred heaved a deep sigh, and averted his gaze as he saw a portion of the apiary slough off into and under the hot mud.

"All going," said he; "all, all."

"Yes," said the doctor, "all is lost here. We must away;" but in a moment more there were shouts of terror—the passage was closed! The tremors increased in violence. There was an uplifting of the entire valley; hot mud and sulphur fumes were thrown high in the air, and now any moment the little party would be overwhelmed.

The two Indian women commenced the death-chant of their tribe, and all waited for the fatal moment.

We are trying a smoker having the bellows-boards grooved, as stated on page 372. It adds but a trifle to the expense of the smoker, and is a great convenience to the manipulator of the instrument.

We have just received two lots of imported queens direct from Italy, from two different breeders, *by mail*, and there was a loss of only 4 out of 24. The success of last season, and this so far, would indicate that we shall not have to resort to the expensive method hereafter of obtaining these queens in little boxes *by express*. But in order to attain success we find it necessary to prepare the cages ourselves, and ship them to the breeders in Italy, with instructions to return queens in them.

W. F. CLARKE seems to rejoice in being a heretic in theology and apiculture and in keeping out of the beaten track. He believes in sugar honey; that the honey-extractor has been on the whole a curse; he would not join

an organization for the special object of prosecuting adulterators, because he believes in producing comb honey exclusively as the best way to meet the adulteration evil.

THE *Nebraska Bee-keeper* has been merged into the *Busy Bee*, with Emerson T. Abbott as editor and proprietor. It is monthly as before, and published at 50 cts. a year. The new series starts out well, for its editor is a practical man of experience. The journal will be devoted to "farm bee-keeping and other minor interests of progressive agriculture." Mr. Abbott is, I believe, employed by the State every fall and winter to deliver a series of lectures on rural subjects at farmers' institutes. If he can throw himself into his paper as he does into his talks his venture will be a success.

In order to give the membership of the United States Bee-keepers' Union a boost we have decided to give GLEANINGS one year, and a membership in the Union for the same length of time, for \$1.75. But in every case the money must be paid in advance; or if there are arrearages, back subscriptions must be paid up to the present, to entitle any one to take advantage of this offer. Or if there are some who feel that they can not afford to pay \$1.75 we offer GLEANINGS the rest of this year to new subscribers, and membership in the Union, both for \$1.35. On this basis you will get seven months' subscription to GLEANINGS for 35 cts.

#### PREDICTIONS OF FAILURE AND DISASTER.

In referring to the attacks that have been made on deep-cell foundation, the editor of the *Review* says he has "no sympathy with the extravagant predictions of failure and disaster"—italics mine. He further adds that he has no fears except that the new product may be tough and leathery, like foundation; and while he can see no reason why it should not be so, yet "so long as Mr. Root says that the side walls, after being finished, compare favorably with natural comb, I prefer to wait till I can try it myself." GLEANINGS has no fault to find with this. As one other writer has said, "If the new deep-cell foundation is a good thing it will go; and if it is not, it will not be heard of long." And I may add, malicious attacks to push it down will and have had the opposite effect, for very often the best way to help along a thing is to fight it tooth and nail.

#### OTHER MACHINES FOR MAKING CONTINUOUS WAX SHEETS.

SINCE the advent of the new Weed continuous-sheeting machinery, it would appear that two or three others are trying to make machines for making continuous sheets. One party employs a large wooden wheel, the rim of which revolves in a vat of melted wax. While continuous sheets *can* be made in this way,

and have been so made for years, they are nothing but dipped sheets, or what we now style "old-process wax." We have seen samples of wax sheets made in one of these machines, and they are identically the same in texture and quality as the old dipped sheets. The Weed sheeting machine not only turns out continuous sheets, but produces a wax of superior texture and quality—tough, pliable, and translucent.

#### MARKETING HONEY.

AFTER preparing the footnote to Mr. Aikin's article, found in another column, the *Bee-keepers' Review* for May comes to hand containing an editorial something in the same line on the Fruit-growers' Union. After mentioning the fact that the California Bee-keepers' Exchange expects to work in coöperation with it, the editor goes on to explain the working of the Fruit-growers' Union. This is what he has to say:

To their sorrow, many growers of perishable fruit, like berries, tomatoes, peaches, and the like, know that a glut in some market so reduces prices that the fruit does not sell for enough to pay the freight and commission. At the same time, within less than 200 miles, the same kinds of fruit may be selling at good prices. The trouble is not that too many strawberries are raised, but that the distribution is unequal. They are often massed in a few points. The grower writes to the commission man, and receives a favorable reply. He ships his fruit; but hundreds of growers have done the same thing. The tendency is to ship to central points like Chicago or Cincinnati, and neglect the smaller towns. The great object of the Fruit-growers' Union is to prevent this massing of products. It has agents scattered all over the United States, and these agents are constantly reporting to headquarters the condition of their respective markets. In the case of perishable products, or whenever the case demands, the telegraph is freely used. Reports are also constantly being received in season regarding the condition of the crops. The General Manager knows, for instance, all through the strawberry season, where the berries are being grown, when they are ripening, how they are "turning out," etc. He also knows where they are being sent, and is promptly notified if there is any tendency towards a glut in the market, or if any market is needing more berries than it is receiving. When a grower is ready to ship, he notifies headquarters by telegraph, saying how many berries he has, and is at once notified by telegraph where to send his berries. The Union has absolute control of the product of its members; and so closely are the markets watched that a shipment is often diverted after it has been started. For instance, it started for Chicago; but while on its way, notice is received that there is a glut in Chicago, while Jackson, Mich., is "short." By means of the telegraph the shipment that started for Chicago has its route changed to Jackson.

Ten per cent of the proceeds is retained as commission; but at the end of the year (I think it is), if it has not cost ten per cent, then there is a rebate. In other words, a member has to pay only what it actually costs to sell his product, and he has the satisfaction of knowing that his product has been sold in what was, in all probability, the best possible market he could have reached.

That one central organization such as the Union is able to prevent a glut in any particular market, for the very reason that it has facilities for surveying the whole field at once, even calling to its aid the telegraph, is a big fact. It is high time that bee-keepers were keeping up with the fruit-growers; and GLEANINGS will cheerfully give space to a thorough discussion of the matter.

## THE THREE STAGES OF AN INVENTION.

AN eminent judge has said that nearly every successful invention has to pass through three stages. First, the invention can never be made a practical possibility; it had better be let alone. Second, when its practical success is assured, "nobody wants it—it will work harm rather than good." Third, after it has passed these two stages, and it is shown to be a good idea, and everybody wants it, then the cry is raised, "It is old; it was in use before; it is common property." The new Weed drawn foundation has now passed the first and second stages. First it was said that foundation with deep cell walls as thin as or nearly as thin as natural comb could not be made; but now that it can be made, it is argued that it will be "ruinous to the industry." If history repeats itself we may soon expect the third stage.

## TAMING APIS DORSATA AND SEMINOLE INDIANS.

THE following note, received from Mrs. Harrison, will explain itself:

Mr. Editor:—I hope you will succeed in introducing *Apis dorsata* into this country. You appeared to think I was poking fun when I recommended turning them loose in the everglades of Florida, among the Seminoles. The everglades are like lakes dotted with small islands, covered with a semi-tropical vegetation. Wouldn't *dorsata* feel more at home there, in that warm climate, with its large flora, than in Medina, Ohio?

If you ever succeed in getting them alive to this country, take a few of them to Biscayne Bay, Miami, or Fort Myers. You could put in your winters in taming them and the Seminoles together, and tell us all about them. Teach the Indian children on Sunday, and *dorsata* to live in a hive on week days. You might succeed in making the price of honey and wax so low that the adulterators will have to take to the woods.

Peoria, Ill.

MRS. L. HARRISON.

If we succeed in getting these bees over to this country we will send our Mr. Root senior down to Florida to see what he can do to tame *Apis dorsata* and the Indian children in that far Southland.

## CORK SOLES FOR USE IN THE APIARY.

FOR a few months past I have been wearing thick cork soles on my shoes. Instead of finding them clumsy, as I feared they would be, they are the easiest shoes I ever wore, and, moreover, they seem to be proof against wet and damp sidewalks. Usually, when going out into the apiary with thin-soled shoes, in walking in damp places the soles would get soaked through, and the result would be damp feet. This spring I found that, with these cork soles, I can go all around in damp places, and my feet keep dry—almost as much so as if I were wearing rubbers. Rubbers are all right; but for one who goes in and out of the apiary, as I do, they are never on when I need them the most; and these cork soles are ready for all kinds of weather.

Oh, yes! I also wear pointed toes, and I consider them a great comfort. The point forms

plenty of room and air for the great toe. Put me down as in favor of thick cork-sole shoes with pointed toes, A. I. R. notwithstanding.

## DRAWN FOUNDATION AS VIEWED BY ANOTHER EDITOR.

IN the last issue of the *Southland Queen* the editor speaks very hopefully in regard to the new deep-cell foundation. This is what he has to say:

We have received samples of the Root deep-cell foundation, and it is as nice as any kind of foundation we have seen; and, while we have not tried it, on account of a honey-dearth being on ever since it came, we do believe it will prove a boon to the extracted-honey producers, if not to the comb-honey raisers. We have had a flow on three days; and as we have been shipping a great many bees lately, we are scarce of combs, and we now ask a question: "Who will be able to tell us what drawn combs or deep-cell foundation would be worth to us just now?" Yea, who can estimate it? If we had this comb to use in 200 strong colonies to-day we should likely get ten to twenty tons of honey in the next ten days, while, as it is, the flow may come and go before the bees can build comb to store the honey in.

A little further on, in the same editorial, referring to the attack upon the article elsewhere in the same journal, the editor says:

On page 15 of this issue, Bro. Hyde puts forth the idea that this drawn comb is a fraud. Now, while it may look a little as though it would injure the sale of comb honey, how can it be classed as a fraud? As a rule, frauds are something that get our money without an equivalent, and this deep-cell foundation will be sold, we suppose, in the same manner as other foundation to those who wish to purchase, and, as one good friend says, "If this deep-cell foundation is a good thing it will go; and if it is not, it will not be long heard of." We think that is just it to a T, and we have no right to be kicking until we have something to be kicking at, and this is just why we have kept as still as we have.

## QUEENS IN THE MAILS.

A SHORT time ago you may remember I reported, from information which seemed pretty straight, that there was a movement on foot in the Postoffice Department to bar queen-bees out of the mails. The United States Bee-keepers' Union promptly took the matter up. General Manager Secor wrote to the department, asking if there was any truth in the report, and received the following letter, which will explain itself:

## POSTOFFICE DEPARTMENT.

OFFICE OF THE GENERAL SUPERINTENDENT RAILWAY MAIL SERVICE,  
WASHINGTON, D. C., May 14, 1897.

Respectfully returned to Mr. Eugene Secor, Forest City, Iowa.

There must be some mistake about this matter, as no one at the department has any knowledge of a change of the regulations excluding queen-bees being contemplated.

JAMES E. WHITE,  
General Superintendent.

This settles the matter. While it did not seem possible that queens should be excluded from the mails, it seemed to be advisable to be forewarned and thus forearmed. The privilege we enjoy of sending queens in the mails is so great that we can not afford to take any chances. In another column there is a case of

carelessness reported on the part of a bee-keeper who ought to be severely reprimanded by the whole fraternity.

J. VAN DEUSEN.

IN our issue for May I appeared an obituary notice of Mr. J. Van Deusen, senior member of the firm of J. Van Deusen & Sons. Mr. V. was 83 years old at the time of his death, and one of the veterans in the bee business. For years the firm with which he was connected has been noted for turning out a beautiful translucent, flat-bottom founn ation. The old gentleman had a secret process of sheeting, and by this process he was enabled to turn out a beautiful article of foundation.

Mr. Van Deusen's face was quite familiar to those who were in the habit of attending the national conventions. One would hardly think that a man of his years could make as long journeys as he did, and yet seem to be hale and hearty, notwithstanding his age, at all the conventions at which we had the pleasure of meeting him. He always had with him samples of his goods, both wired and unwired.

He is the only one, I think, who ever, in a commercial way, incorporated wires into the

J. VAN DEUSEN.

foundation itself, the wire being inserted, evidently, in the process of milling. It is doubtful whether the wire could be inserted in the natural-base foundation. It *could* be put in, but would be kinked up by the faces of the mill, so as to make it practically a rail fence that would stretch as much as the foundation itself.

The firm is still operating, the younger member, I believe, having charge of the business,

and I have no doubt the quality of goods will be up to its former high state of excellence.

It is a pleasure for me to state that the half-tone portrait is very natural, and will be instantly recognized as such by all who have had the pleasure of meeting the senior Van Deusen at the various conventions.

#### A HONEY-LEAFLET IN ENGLAND.

A LITTLE pamphlet entitled "Honey and its Uses," by Rev. Gerard W. Banks, is being circulated, as I judge, among honey-consumers in England. There are several good things in it, and from among them I make the following extracts:

Apart from the consideration of the many other valuable properties claimed for honey, the following facts, which seem well authenticated, must certainly go far to recommend its use as an article of food:

1. The sugar of honey, being in the most suitable form for assimilation, requires hardly any digestion. It is in a condition to enter at once into the system.

2. It is, in a usual way, not liable to occasion any disorder of the system, and may therefore generally be used by those with whom ordinary sugar is found to disagree.

3. The grape sugar of honey does not cause decay of the teeth as cane sugar does.

These statements, of course, have reference only to honey that is absolutely *pure*. Erroneous opinions, and much mistaken prejudice, have unfortunately arisen with regard to the use of honey, owing to the unpleasant effects upon many persons of the various compounds, consisting chiefly of glucose made from potatoes or rice, and sulphuric acid, which of late years have been in such large quantities sold as a substitute for pure honey. It is of the greatest importance, if its beneficial effects are to be enjoyed, that the honey consumed be pure.

Till comparatively recent times honey was the chief sweetening agent in use. After the introduction of cane sugar, however, the use of honey in this and other countries largely declined. But there is no doubt that of late years it has been more and more realized that pure honey does possess qualities which it is impossible to replace. There has been a larger and ever increasing demand for it, till there seems every prospect of its coming again into general use in every household. Thousands of tons of honey are now annually consumed in this country; while in North America alone, it is estimated that more than a hundred million pounds are produced every year.

But it is not only as a palatable and nourishing food that honey has again come to be so highly appreciated. It is now pretty generally acknowledged to be a really valuable medicine. And when we bear in mind that the nectar gathered by the bee is a secretion in which we may expect to find the essential virtues of the plant from which it is obtained, that there is more or less pollen always present, and that, when converted into honey, it contains, in addition, a certain amount of formic acid, we can easily account for its wonderful medicinal properties.

Honey is especially recommended as likely to be beneficial in cases of dyspepsia, rheumatism, asthma, hoarseness, shortness of breath, and all affections of the chest. Consumptive people are known to have derived great benefit from its continued use, and it is said to have been recently often used as a substitute for cod-liver oil, with very satisfactory results.

In bronchitis great relief may be obtained by taking a small quantity at frequent intervals. The regular use of it is said to aid digestion, and to strengthen the nerves. As a gentle laxative, and purifier of the blood, no better medicine can be taken; while its peculiar acid property has caused it to be generally recognized as a valuable medicine in cases of sore throat. Indeed, for coughs, colds, and all affections of the throat it is universally acknowledged to be the best of remedies.

Owing to the unusual amount of wet weather I did not get off for a wheelride this spring until yesterday, May 18. Once more I passed through that remarkable experience of a long wheelride. For some time back I have been troubled with my old chills. I have been wearing my overcoat and fur cap. In fact, I debated some as to whether I should not take my overcoat along when I started out for my ride. For some days back I have been getting so tired before noon and before night that I really began to question whether I had strength enough for a long ride. A good nap of about an hour before dinner, and another one before supper, had helped me to get along and look after my appointed part of the work. Well, I decided to leave my overcoat at home, even though I felt chilly for the first four or five miles. I not only felt chilly, but began to get tired; and had it not been for my previous experience I think I should have turned around and gone back home and given it up, thinking I was too old and too much out of health for any such hard exertion. After I had gone about ten miles, however, I was singing my old hymns, and thanking God for the "second wind" that was beginning to thrill my whole being. When the usual time for my nap came I felt unusually wide awake; and in an hour later I was in excellent trim for a good dinner which I found at a hotel on my route. I rode the last ten miles in my shirtsleeves, with my coat tied to the handle-bar, and I wished several times I had one of my summer hats instead of the fur cap. I made about 30 miles easily, and arrived home just in time to take charge of the boys, and worked hard until supper-time, with no thought of a nap, and then helped to push some other work that needed to be done, until well toward sundown. Then I slept a good hour as only the tired laborer can sleep, and had an excellent night's rest after that. During the latter part of my ride I chose an untraveled road because it was shorter, and this threw me into a good perspiration. After I arrived home I drank as much water at intervals (from that new soft-water well) as I drink ordinarily in a whole week. To-day I am feeling very much better than if I had not taken any ride at all.

But most of my readers, I suppose, know all about this. Wheels are now so common that it is hardly worth while to go over such experiences, and I have given this mainly for the benefit of the elderly ones who think they are getting to be too old, or that their health is too poor for such youthful sports. Perhaps some of you wonder why the craze for wheeling holds out, and increases to such an extent. Well, I suppose it is for the reason I have just given above.

At the Creston celery-farm I found my friends all busy; and expert women were swiftly transplanting the little seedlings into boxes, on the plan I have several times described. These boxes were then put in the hot-beds outside. And, by the way, this perhaps quarter of an acre of hot-beds and cold-frames is a sight indeed. I wish I might give you a photograph of it. It reminded me of the chapter in our tomato-book, about supporting a family on a quarter of an acre. Mr. Jordan says this quarter-acre would keep a pretty good-sized family busy several months in the year. Some

of the beds are covered with cloth, and some with the glass sashes. All of the glass is, however, whitewashed at this season of the year. The greater part of the beds have pipes underneath them for steam heat; but this spring they have added a new block without steam heat. These answer every purpose a little later in the season, or they will answer earlier for hardening off plants that are pretty well rooted. By keeping the beds damp with plenty of water and a cotton-sheeting covering, they make them stand up from the day they are planted until they are ready to go out into the field. In fact, I saw one bed full of plants put out only yesterday, and every leaf stood up apparently full of life and health—no hurt from the transplanting process whatever; and yet when the plants are taken from the seed-bed the soil all drops off, and nothing but the naked roots are put into the boxes. This speaks well for their compost of swamp-muck and well-rotted manure.

It seems to me I never saw such beautiful beds filled with boxes of plants. These boxes are lifted into a wagon made for the purpose, and carried right out into the field; and their arrangements were so complete that it did not seem to me as if there was a missing plant in ten thousand. Each plant has a great bushy root, and in fact this bushy root carries along a goodly lump of the compost contained in the box in which it grew. This compost is swamp muck, two parts, old well-rotted manure one part, thoroughly commingled.

Before I got in sight of the grounds I broke forth in an exclamation of surprise. Yes, I have done this a good many times at the beauty of these newly planted celery-fields, but *this* time there was a new surprise. Off in the distance there was something more enchanting than any thing I had ever seen before. It was a whole block of *five acres* devoted to the new celery culture. The Jordan Brothers, however, have modified the process somewhat, so as to fit appliances of their own. The plants were spaced at an exact distance of  $3\frac{1}{2}$  inches apart in the row, and the rows were a foot apart. This spacing is all done by appropriate machinery. The rows run crosswise of the beds, and they are just 15 feet long. Then between the beds there is an alley or driveway wide enough for a narrow-tracked wagon. This driveway is to carry in the boards, and to afford a place for the workmen to stand as they handle the boards and place them up against the rows of plants. It is the "new celery culture," but they use boards for bleaching. They say they do not get any real nice celery without the boards. Now, with the rows 15 feet long, and the boards 16 feet, a man in each alley can place them without tramping on the plants at all. You see they have my idea of plant-beds so the ground need not be tramped down hard. They use about 24 tons of good stable manure to the acre, besides a large quantity of bone-dust, and ashes or potash in some other form. □

The variety used almost exclusively is the Golden Self-blanching; and it was this golden color that caught my eye. No flowering plants ever grown by florist were so handsome to my eye as that block of five acres. It looked as if a gorgeous sunset had blazed down for a moment on that little square block of swamp muck. What astonished me was to see each plant so exactly like its neighbor; and there they stood, thousands upon thousands—no failures, no weak puny plants. Mr. Jordan put down his hand and pushed away the muck to let me see the great masses of snow-white roots that were reaching out for food and drink.

I took a new route home. In my wheelrides

you know I always take a new road when I can. Constance says this is so I shall get lost and have some adventure. I did not get lost this time. I did, however, run across another celery-ranch. A bright gleam of color caught my eye from a sort of plant bed or greenhouse. This bit of color was Grand Rapids lettuce. It was still standing in the seed-bed; but its cotton-cloth covering had bleached it so it had that fascinating light green, almost white. I asked the young man who owned the ranch if his lettuce-plants were not getting pretty tall. He explained that they cut off the tops with shears, and used or sold the lettuce, and then waited until the roots had started again, producing much the same result as transplanting, with less expense. This man had an engine to warm his beds and pump his water, and a lot of iron pipe to carry the water all over his little farm. He has not got his drainage quite as perfect yet as the Jordan Brothers, but I think he will make a success of it eventually. In drilling for water he struck a flowing well—at least the water boils up over the top of the iron pipe, and runs away. The water rises only a little higher than the level of the surface water in his ditches.

Further on I visited the onion-farm of Mr. Barnhart, and found him using one of the Breed weeders I illustrated in our previous issue. Excessive rains prevented him from using the weeder so as to kill the weeds before they were "burned;" but his men were at work with wheel-hoes and weeders, getting his patch ready so the weeder would do the work for the rest of the season if we are not drowned out by too many heavy rains. If the price of onions will only hold up to \$1.50 a bushel or \$5.00 a barrel, what a picnic we shall have when marketing time comes! and, as usual, I expect to have American Pearls and Whitakers on the market before anybody else has anything large enough to call an onion.

## OUR HOMES.

And it came to pass the same day, that Isaac's servants came and told him concerning the well which they had digged, and said unto him, We have found water.—GEN. 26:32.

And whatsoever ye shall ask in my name, that will I do, that the Father may be glorified in the Son.—JOHN 14:13.

□ That whole 26th chapter of Genesis has always been interesting to me because it has so much to say about digging wells. In my earliest childhood I was greatly interested in wells and springs, especially the soft-water springs round about my hilly home in Mogadore, Summit Co., O.; and I soon learned to enjoy drinking the pure cool water from certain springs; and when away from home, where I was obliged to drink hard water from wells, I always found it quite a cross. In view of this it is not strange that, when the oil excitement broke out in 1860, I became deeply interested in exploring the depths of old Mother Earth for the treasures (or God's gifts, if you choose) which were just then thought to be stored away, awaiting man's energy and inventive genius to bring them to light. I have told you about well-digging on our own premises, and of the two soft-water wells that rejoiced our hearts as a reward for our researches in the way of well-digging or drilling, rather. And, by the way, I am now feeling happy every day because one of those wells I told you about is now supplying our whole town of Medina with pure soft

water. While putting in new waterworks there was no readily available plan of keeping the town supplied unless the pumping-engine was located at our first soft-water well; and it is at this very moment while I write doing duty by supplying the town.

Perhaps I have already told you that we have digged and drilled seven different wells on our premises, and all of these have been put down since we came here, nineteen years ago. After securing these two wells of soft water, especially when we were using only *one* of them for our own premises, it would seem that we should be content. Not so, however. The well at the windmill upon the hill was put down 99 feet, and gave an abundance of very hard water, unfit for steam-boilers, and unfit for *drinking* after you have once tried the water from the soft-water wells—at least, that would be my verdict.

The windmill has been standing idle ever since the soft water was found. It must have continued to stand idle unless we did one of two things—move it down to the creek bottom, where there is comparatively little wind unless we have a very expensive high tower, or drill the well deeper at the windmill, so as to strike the same vein of soft water. We finally decided, during the month of March, to try drilling the well deeper. The well-driller preferred to make an entirely new well at his usual price—something like a dollar a foot for a six or eight inch bore. He said he did not like to fuss with wells already put down; but he agreed, however, to work for me, giving the use of his tools, and one man besides himself, for a dollar an hour; but I had to take all chances of pulling up the old tubing, and getting the smaller hole reamed out, etc. I chose the latter plan. In the first place, it was somewhat doubtful whether the old tubing could be pulled out, for it was driven very securely into the rock (sixty feet deep), and had been in place over seven years.

We procured a stick of timber for a lever, 30 feet long; made a very substantial foundation for a fulcrum; and although we succeeded in breaking our heavy chains, the tubing would not budge. After we had wasted considerable money in this way, we substituted two powerful screws in place of the lever. Once more it seemed as if no power on earth could pull up that iron pipe. We might pull it in two, but it seemed so firmly imbedded or driven into the rock that it would never move. I began to feel nervous over so much waste of time and money, and, as a matter of course, began to pray that God would help us in our efforts to get pure water, as I had prayed more or less over all the other wells on our premises.

"Boys, are we not getting it started just a little?"

The man who was bossing, the job replied: "I do not think, Mr. Root, it has started a particle."

I had prayed over the matter in the morning before starting the work, and I mentally prayed again that God might help us where we seemed to be helpless. If I remember correctly, it was not many minutes after this silent prayer, that somebody called out:

"We are all right! she's starting!"

We could hardly believe the good news until careful measurement showed that it had moved something like an eighth of an inch. The screws were turned again until every thing began to snap, and the boss told us to hold on a little and give it *time* to come. Pretty soon we had made a whole quarter-inch; then a whole inch; finally several inches, and the little steam-engine with its powerful derrick soon

grabbed hold of the rusted tubing and laid it safely on the bank. We were all right. But the rock was now found to be 60 feet deep instead of 40, as I had estimated it. No record had been kept of our former drilling; therefore we were at a standstill until some more eight-inch casing could be ordered. The men were on hand, the machinery in position, and every thing ready to go on. We telegraphed for tubing, but it did not come, and could not be found. The owner of the machinery consented to wait a reasonable time at his own expense; but when day after day passed, and no trace, even when we wired tracers again and again for it, I presume he too began to tire of waiting.

Dear friends, on some accounts I dislike to tell in public print how I have worked and prayed in building up our present business. I do not feel backward about telling my wife or my good old mother about these answers to prayer; but I have often thought I ought to be very careful about telling these things in such a public place as a printed journal like this. I would say to you, however, that this little incident about drilling this well is no new experience of mine. For nearly twenty years past, or ever since my conversion, it has been my daily custom to breathe that little prayer, "Lord, help!" whenever I get into any sort of trouble. Of course, I keep in mind that God can not consistently answer my prayer unless my undertaking is a praiseworthy one. If I were going to build a finer house than my neighbor's, or if I wanted a gold watch and massive gold chain to make people stare, I should not think of asking God to help me in getting either one. No doubt many of my desires are selfish ones, for I am human, and sometimes I am led to feel that I am *exceedingly* human. We are told in God's holy word, "If I regard iniquity in my heart, the Lord will not hear me." Therefore he who expects the Lord to hear and answer his prayer must be very careful that no iniquity or selfishness is at the bottom of his undertakings.

The pipe did not come. My friend over at the depot, the agent, said there was no possible way for the tubing to get here before the next afternoon; and the owner of the well-machinery did not want to wait much if any longer, unless I paid him for his time. Besides, I felt impatient at the delay, and was exceedingly anxious to have the work go on. I was up quite early next morning. The weather was just beautiful for this outdoor work, and we had been having previously some very bad weather. I was up in that particular room in the office where I often pray over my plans, and I was wondering if that tubing could not come in some unexpected way so we could have it right off that morning, notwithstanding what the agent said. I remembered that passage in Scripture which says, "The Lord's hand is not shortened,"\* and the other one that speaks about even the winds and the waves obeying him. I prayed that, if it were consistent with God's will, he might, in some way beyond my comprehension, bring about the missing pipe, even before the afternoon train. I went downstairs with a lighter heart. Just then one of the men who had come early to commence his day's work said to me with a smile, "Mr. Root, that iron pipe you wanted so badly lies out there on the end of the sidewalk."

You may be sure I was somewhat startled. Yes, I have been startled in this way many times before. The explanation of it was quite

a simple matter after all. The railroad company, by some blunder, had carried the pipe past its destination. They brought it back and unloaded it some time in the night. The foreman of the lumber-yard, knowing how badly I wanted it, had pulled it up on his horse-car and placed it where I might have almost stumbled over it. In fact, it was lying right there in plain sight at *the very time* I was praying about it. Some of you may suggest that it was no answer to prayer at all, because the prayer had nothing to do with it. It was *already* there. In reply, let me refer you to a passage in Isaiah, 65th chapter, which says, "Before they call I will answer; and while they are yet speaking, I will hear."

Please be patient with me once more, dear reader. The large eight-inch well-casing I had purchased was second-hand. I chose this kind because it was a good deal cheaper; and as it was to be pulled out afterward it would likely answer every purpose. When it was nearly down to the rock (in order to cut off the hard surface water) the well-man stopped and listened. Water was pouring down in the well. In fact, there was a little waterfall. I laughed, but he looked sober. Said he:

"There is a break in that casing. I was afraid of it, as it was so old and thin."

They put on the tongs in order to see if it could be screwed up; but he soon announced that the thread was spoiled away down in the well, and then he looked more troubled still. Said I:

"Mr. H., can't we pull it up and fix it?"

"We can pull up the top part of it, but there is no way in the world to pull up the lower part, that I know of."

All at once I thought of my answers to prayer in pulling out the old tubing, and in having this very same new casing delivered that morning right at my feet when I so little expected it. To my poor human vision it did not seem probable that God would hear me in that way if it were to result in hopeless disaster like the one right before us. I said again, mentally, "Lord, help!" Let me explain that I was at the time worried with other cares down at the factory, besides this well business, and I could ill spare the time to look into the matter and direct what was to be done next, in order that the expensive men and machinery might not stand still waiting for direction.

"Mr. H., I can hardly believe the pipe has pulled in two. Put on your tools and see if it is not possible to screw it up so it will hold at least long enough to draw it out."

"I will do just as you say, but I am sure it is not a bit of use. We have turned it and turned it; and from its actions I am satisfied it just slips a thread every time we go around. The top will lift right off, but the bottom is *gone*."

I was thinking of the duties and responsibilities that called me to other places, but waited until they began turning the great pipe to see if it might not catch on again. Pretty soon the face of the manager began to soften into a smile. Finally he said:

"Well, I declare! I believe that has caught and screwed down solid; but I never before, in all my experience, saw any thing get into shape away down in the ground like that."

They tapped it gently with the big pile-driver hammer, and it seemed to go down all right. Another piece was screwed on, and before night it was firm and solid in the great bed-rock, and we were ready to go on with our drilling. Mrs. Root and some others asked how we could be sure of getting soft water away up there on the hill. I replied that there was hardly a question about it, for we had got soft water in so many

\* Behold, the Lord's hand is not shortened, that it can not save; neither his ear heavy, that it can not hear.—ISA. 59:1.

places; and when word came to me along in the afternoon that they had got the soft water, I remember distinctly of feeling a little ashamed of myself *because* I did not thank God more earnestly in my heart for having brought us safely through our troubles, and enabled us to secure the coveted soft water once more. I directed, however, that they should drill five or ten feet deeper in order that the sediment might settle below the point where we expected to place the pump. Well, after we had drilled five or six feet *the water was hard*. I did not examine the water myself, or at least not very thoroughly, when they told me they had soft water. It was now *unquestionably* hard. We put down the pump and worked it for several hours. There were great quantities of water, but it was unfit to put into the great tank beside the windmill. It would spoil all of our good water. I was a good deal disappointed. I feel ashamed to acknowledge it, but I am afraid I began to be just a little doubtful in regard to those strange answers to my prayers at the different times I have spoken of. I am afraid I was forgetting one of my good old father's texts—"Though he slay me, yet will I trust in him."

Please, friends, do not pass judgment on my Home talk in this issue until you hear what further I have to say on the same matter; and do not, let me beg of you, lose your faith in the great God above, even if he does *not* give you just what you ask for, in just the way you *expected* it to come.

#### HOW TO TELL WHEN THERE IS GOING TO BE A FROST.

Candidly, I don't know; but I do know from experience something about it. On the night of May 20 we had a big rain. Before the rain the thermometer stood between 70 and 80. The next morning it was down to 50; and I knew, before the Weather Bureau said so, that the conditions were going to be favorable for a frost that night—that is, if it cleared off. So you may be sure I watched both the thermometer and the barometer all day long. About a week ago the indications were so strong for a frost that we spent a couple of dollars in getting our sashes on, and covering tomatoes, strawberries (that had been grown under glass), etc., for three nights. We came very near frost, but there was not any to do any damage. All our fuss in carrying things, and the attendant litter, was time wasted. A year or two ago, however, one night when I decided to take the chances, we had lots of nice tomatoes badly damaged after I had carried them through March, April, and a part of May. Well, last evening I felt very much averse to getting out our sashes again. They were nicely put away for the season, with the big boxes that sit over them inclosing and protecting each pile. It is heavy business lifting off those large boxes, and we almost always have more or less broken glass in handling our 150 sashes. I was watching the barometer and thermometer, watching the wind, and watching the clouds. The boys were quite willing to go to work and make every thing safe, but I told them I would take the chances.

By the way, just across the street from where I write there are some of the Earliest in the

World tomatoes trained upon poles. Some of them are three feet high already; and I tell you it is a job to blanket them. We did it, however, last Saturday night, and the structure looked so queer that passersby began to banter me about fixing for a variety show. On Sunday morning, before I got my cotton sheeting and other "drapery" off from the plants a horse got frightened at the unusual spectacle. Well, in thinking this all over I decided to take my chances, even though the barometer was hitching up a little for a clear night, and the thermometer was down to just about 50 at sundown. (One of our rules has been that there is never much danger of frost while the mercury stands above 50° at sundown.) Besides, it was a little cloudy in the west, and I told the boys they might all go home. Just as the sun was disappearing, however, it met a streak of clear sky under the clouds; and by nine o'clock we had a clear starry night. The thermometer, however, stood a little above 40. I got up at midnight, and the mercury was down to 38°. I told Mrs. Root I was going to have a "picnic" about the first glimpse of dawn; for I had noticed several times that the coldest period was between dawn and sunrise. In fact, I have seen plants frozen *after* sunrise that were not hurt a bit until that time. At half-past three it was light enough to see, and the thermometer stood at 36. The frost was white and thick on the roofs of buildings, sidewalks, and every piece of exposed timber. At first I thought the tomato-leaves were frosted; but a little more daylight showed they were simply loaded with a very heavy dew.

When the thermometer got down to 35½ I began to think I should have to call up Huber to help me cover up the stuff, even to protect it for a single hour. I walked all over the garden, watched Nature's performances, and then held my breath (so as not to breathe on the bulb) while I watched the thermometer again. It would not budge a bit from 35½. About four o'clock, however, it was perceptibly rising, and I began to rejoice. At half-past four it went down again all it had risen, and a little more. I climbed up to the highest point accessible, and watched for the sun. I would have hurried old Sol up a little, but I did not know how. When his rays began to touch the top of the windmill tower the thermometer deigned to hitch up a little. I kept fingering the tomato-leaves, and saw they were all right. When the sun was clear up above the horizon, and his rays burst forth in all their glory over the tomato-plants and every thing else, *then* I rejoiced. Not a sash had been moved, not a sheet or blanket carried out, and my whole garden was unharmed. Out in the apiary a few sweet-potato plants had their foliage blackened a little—that was all.

I have gone into all these details, dear readers, because it is exceedingly important that the gardener should learn to judge with considerable accuracy, that he may not waste money in handling sashes needlessly, and, on the other hand, that he may not take risks recklessly, and do a worse thing. Now, if you know of any better way of steering clear of both these extremes I should be very glad indeed to get hints on the subject.

#### "THE EARLIEST," STRAWBERRY.

These berries are now ripe, but there are not very many of them. Thompson's Sons, of Rio Vista, Va., say that it will be more productive in two or three year-old beds. This I can readily understand, if the runners are pulled off. In fact, by the way it commences to send out runners as soon as blossom-buds are visible I

feared we should never get any good berries unless I pinched the runners off, which I did on a few, and the berries are very much finer and larger. The introducer says one dozen plants will make a *thousand* on ordinary soil in a single season. The shape is perfect. The color is pretty light, and the berry is soft. But it is so far ahead of every thing else in ripening that I think it will be worth while to have at least a small plot of it on which to open up the season. It very much resembles Michel's Early, but I think it is considerably earlier—probably just about as productive. My impression is that all berries of this class should be planted in hills, and the runners kept off.

WHAT STRAWBERRY AMONG OUR WELL-KNOWN VARIETIES WILL GIVE THE GREATEST NUMBER OF BUSHELS PER ACRE?

"Mr. Green, the Ontario Experiment Farm have made a test of 121 varieties of strawberries, including almost everything that is known and talked about, and they have given the number of ounces produced by one dozen plants—that is, one dozen plants were put out and allowed to make a matted row, and the berries were gathered and weighed the next season. Now, can you guess which plant gave the largest number of ounces in the whole 121?"

My remarks were made to Mr. E. C. Green, who was formerly connected with our Ohio Experimental Farm. As I spoke he smiled good-naturedly, tipped his head a little to one side, and said:

"The largest yield? Let me see. Why, I shouldn't wonder if our old friend Warfield has found a place pretty near to, if not quite at the head of the list."

Then I had a big laugh. As sure as you live, Warfield heads the list of the whole 121, with a yield of 294 ounces. Edgar Queen comes third, with 244. Haverland falls in line as No. 10, with 205 oz. You may be sure I felt a little pleased to find at least three that we have held on to for many years standing so near the head. Bubach comes along as No. 18, with a yield of 185 oz. Michel's Early is 48, 140 oz. I have not retained this because of its large yield, by any means, but because it was earlier than any thing else. Jessie comes in 66 in the line, with 105 oz. On our grounds I think it would do rather better than this, although it does not do tiptop except during an occasional season. I was a little disappointed to see the Marshall put just one ahead of Jessie, and I was still more surprised to find Parker Earle No. 91, at only 56 oz. The truth is, the Parker Earle wanted richer ground and larger quantities of manure.

Now, what do you suppose was the *poorest* in the lot? Why, it is the Alpine Everbearing; and it would hardly be worth while to give the Alpine a place at all were it not that it furnishes a few berries all summer long, and these few have that wonderfully delicious musky flavor.

Let me now go back to No. 1. It has been one of my favorites for a good many years, and I feel like petting it a little, as below:

"Dear little Warfield, it rejoices my heart to see my faithful little friend given such a high post of honor. Your berries are not as large as the Bubach, Sharpless, and some of the newer varieties, it is true; but not one of them all has that beautiful rich garnet that makes it shine like a gem, as you do down among the green foliage. And there is no *humbug* about your shining, either, dear little friend; for whenever one utters an exclamation of surprise at your beauty—beauty in shape and beauty in color—he gives place to a still more joyful expression

of pleasure when he tastes that delicious tartness; and I suspect, little friend, that if you had plenty of room, rich soil, and had the runners taken off, as we do with some of the newer kinds, you would show us some wonders in the way of size that you can not when everybody lets you set the plants so thickly that it makes me think of a family of children so large that the good mother can hardly find food for them all."

CRIMSON CLOVER.

Our crimson clover is now in full bloom, and it is a sight indeed. I learn from Prof. Thorne, of the Ohio Experiment Station, that they also have succeeded during this last winter in wintering it over. A neighbor was in here a few hours ago, who says he has ten acres. It was sown among corn at the last cultivating. He thinks the stand was almost as good as mine. He plowed it under, and is now going to grow corn again on the same ground. From reports received it seems to be succeeding well through Northern Ohio, especially along near the lake, and several reports have come of successful wintering in York State.

POTATO-BUGS ON TOMATO-VINES.

If you plant tomatoes on ground that potatoes have occupied the year before, you will be sure to be troubled with bugs; and if you do not look out they will eat up your tomato-vines entirely. Dust them with Paris green, just as you do potato-vines. Any of the dust-distributing machines we advertise will do it to a dot. A very little of the Paris green suffices, and it lays them out almost instantly.

THE GLEANINGS CONTRIBUTION FOR THE STARVING PEOPLE IN INDIA.

We did not expect to open a subscription-list in GLEANINGS for this purpose, but I do not see but we shall be compelled to do so. See below:

A. I. Root:—I read to day in your journal of the famine-stricken people in India. Inclosed find \$2.00 which I wish to send to them. I knew of no place to send the money, so I thought you would see that it reached them.  
LYDIA WAGNER.

Calamus, Iowa, May 21.

Mr. Root:—A woman in Kansas sent me this five-dollar bill, to have me put a white wreath on a friend's grave next Sunday morning. I will put the wreath on the grave, as she desires, but it seems too bad for so little good. I will send it to you, to send the quickest way to help some of those famishing children in that land of darkness and drouth. May the Lord's blessing go with it.

Pleasant Hill, Mo., May 25. — GEO. M. KELLOGG.

We will add \$25.00 to the above, from the A. I. Root Co., and forward the whole to Sec'y Judson Smith, D. D., Congregational House, Boston. To save time I would advise contributors to remit direct as above. You can, at the same time, inform us what amount you sent, and we will publish your letters, if brief, in this department of GLEANINGS. God will surely bless those who make a sacrifice to relieve starvation and suffering.

THE AIR-SHIP.

I am told there is an air-ship, after all, and they have it at the National Exposition at Nashville. I am very well aware that they have a balloon there that they call an air-ship; but a balloon that goes wherever the wind happens to blow it is quite a different affair, dear friends, from a ship that sails through the air wherever one wants to go, as a steamship goes over the water to its destination.

#### NO. 2 SECTIONS OPEN ALL AROUND.

We are still short on No. 2 sections, except as you can use them open on four sides, can supply this style in No. 2, 2 in., 1 1/8 in., or 1 1/4 inches wide, very promptly. We are turning out 90 to 100 M sections every 24 hours during the week except Sunday, and they go out as fast as we can make them. We are now making from inch lumber, and have a surplus of narrow widths, 1 1/2, 1 3/4, and 7 to foot. The tendency is for the use of narrower sections. In Canada the standard is 1 1/2.

#### SMITH'S NOVELTY FORCE PUMP.

The spraying season is not yet past, but just at its height. We have an extra supply of Smith Novelty force pumps. This is undoubtedly the best tin pump ever made. We have sold them for upwards of fifteen years, and they give universal satisfaction. For a cheap force pump they have no equal. Being made of tin they will not last as long as a brass pump, but you can afford to buy four or five of these for what you would pay for a good brass pump. For the next 30 days we offer these pumps at the following special prices: 75 cents each; 3 for \$2.00; 12 for \$7.50; 24 for \$14.00; a crate of 3 doz., \$20.

#### MOHERMAN SPRAY-PUMP.

We have also an extra supply of the Moherman spray pump which we took in a trade. It is an excellent brass pump, with air-chamber, rubber tube, and sprinkler and spray nozzles; is very similar to the Myers pump we have been selling for several years, usually retailing for \$5.00. For the next 30 days we offer these at \$2.00 each, or \$5.00 for 3; \$18.00 per dozen. Catalog and fuller description of these pumps will be found in our seed catalog, among our other spraying-pumps. We make these special prices for only a limited time, to reduce stock.

#### BUSINESS AT THIS DATE.

We have not had such a rush of orders since 1890, and we hear from other manufacturers that they are having a rush as well. We have been running our factory day and night for the past six weeks in the effort to keep up, but we have been losing ground the past two weeks. We are about one week behind on orders. Of course many orders go out in less time, some of them the same day received, or next day, but the larger part of the orders take a week before we get to them. As the demand usually is greatest in May and lets up in June, we expect to gain rapidly on orders from now on so that we hope within the next two weeks to catch up. We have on hand ready for immediate shipment several hundred regular No. 1 Dov. hives, 1896 style, with Higginsville cover. If any want hives in a hurry and can use these we will agree while they last to get them off promptly. The price is 5 cts. each less than this year's style, and they are packed in crates of five in flat complete. Our Chicago and St. Paul branches can also supply the same kind.

### Special Notices in the Line of Gardening, etc.

By A. I. Root.

#### PACKING WINTER APPLES IN SAWDUST, ETC.

I am reminded that, in my editorial on page 396, last issue, I was a little more severe than the circumstances perhaps warranted. I confess I was a little bit stirred up to see this man getting 50 cts. for telling people how to keep apples in sawdust. I received the recipe just before going to press, and barely had time to get in a note of warning. I had seen the advertisement in the *Ohio Farmer* only; but I did find a scrap from an agricultural paper, advising everybody to send for this recipe, saying they had just received a basket of beautiful apples from Mr. Wright, etc. This scrap of paper was not from the *Ohio Farmer*; but I am now told the same

advertisement had been previously accepted by three other agricultural papers. Perhaps the reason why I saw the advertisement in the *Ohio Farmer* and overlooked it in the three other papers (for they all come to my desk regularly) is that I read the *Ohio Farmer* with more care, advertisements and all, than almost any other agricultural paper. It is published near my home, and I am personally acquainted with some of its editors, and I hope and believe they are personal friends of mine. I have known the *Farmer*, and read it, almost all my life, and I humbly beg pardon of the *Farmer* people and of all of our readers if by my vehemence I seemed to show want of respect to or throw discredit upon that excellent agricultural journal. I do not know of any other agricultural periodical that has more articles from our best practical farmers—good common-sense articles—published without fear or favor, than the *Ohio Farmer*; and if it went into more of the homes of our farmers all over the country there would be a "heap" less money wasted on agricultural swindles.

#### SELLING RECIPES AND SECRETS FOR DOING SOMETHING.

One of our readers thinks A. I. R. had better go for the poultry-journals. He says they are full of recipes for making things for killing vermin on poultry, to make hens lay, etc. Now, what in the world is to prevent the editor of each and every poultry-journal, accepting such advertisement, from sending the 50 cts., getting the recipe, and publishing it to all his readers? The recipe oftentimes takes less space than does the advertisement that proclaims the wonderful virtue of the "great discovery," etc.

#### 500 BUSHELS OF POTATOES GIVEN AWAY DURING THE LAST TWO WEEKS; 1000 MORE TO BE GIVEN AWAY DURING THE MONTH OF JUNE.

At the present date, May 29, we have remaining of Maule's Thoroughbred, 125 bushels of firsts, 238 seconds; Early Ohio, 20 bushels firsts; Early Northern, 4 bushels; Burpee's Extra Early, 4 bushels; Freeman, 130 bushels firsts, Terry's own growing; New Queen, 95 bushels firsts, 90 of seconds; Monroe Seedling, 15 bushels; Rural New-Yorker, 5 bushels; Sir William, 185 bushels; Carman No. 1, 22 bushels; Koshkonong, 5 bushels; New Craig, 83 bushels of firsts, 12 of seconds.

Our friends will notice that we have more of Maule's Thoroughbred than of any other variety. I presume this is owing to the fact that they gave us such an enormous yield last season. We want every reader of GLEANINGS to try these and have a good stock; therefore we make the following offer until they are sold out or planted:

#### A BARREL OF THOROUGH-BRED POTATOES FOR EVERY NEW NAME.

Every reader of GLEANINGS who sends us a new subscriber, and introduces it into some new locality, as we have heretofore explained, may have a barrel of Thoroughbred firsts for every new name sent; or he may have a barrel of any other variety named above; or a barrel made up of mixed varieties, as he chooses; a barrel of potatoes for every new subscriber, with \$1.00 accompanying.

#### A BARREL OF THOROUGH-BRED SECONDS FOR EVERY DOLLAR RECEIVED FOR GLEANINGS.

For every renewal, or every dollar sent us for GLEANINGS, past, present, or future, you may have a barrel of Thoroughbred seconds, or a dollar's worth of any other potatoes mentioned in the list. With the cool weather we have been having through all the month of May, our potatoes are in very fair order for planting, and we think they may all, or nearly all, be planted safely at any time during the month of June, but the sooner you get in your orders the better, as a matter of course.

All potatoes go off first train.

I write to say that potatoes were received in good time, and in the most perfect order. The Rural New Yorker potatoes were the most handsome of the kind that I ever saw. In fact, all were fine.

Pleasant Valley, Va.

C. W. RICE.

[Friend R., I wonder if it is not somewhat owing to the name of the place of your abode that you are so well satisfied.—A. I. R.]

Are You Going to Buy \_\_\_\_\_

## Apiarian Supplies or Bees?

If so, You Want the Best.

This is the only quality we offer. Our prices are right, and our '97 catalog describing them, and the management of bees, is yours for the asking.

We carry a large stock, and can ship promptly. Freight is a big consideration, often amounting to 20 per cent of the value of goods. Let us quote you prices on what you need, delivered at your station,

## Freight Paid.

They will cost but a trifle more than others charge at the factory. Our aim is to please.

Apiary, I. J. STRINGHAM,  
Glen Cove, L. I. 105 Park Pl., N. Y. City.

## Don't Neglect Your Bees.

Bee-keeping may be made uniformly successful by judicious feeding. It is just as important with bees as with other stock.

Success in feeding depends very much on the feeder used. When you have tried the

**Boardman Atmospheric Entrance-feeder**

you will be convinced of this.

For descriptive circulars and price list, address

H. R. BOARDMAN, East Townsend, Ohio.

## Dovetailed Hives.

Sections, Extractors, Smokers, and every thing a Bee-keeper wants. **Honest Goods at Close Honest Prices.** 60-page catalog free.

J. M. JENKINS, Wetumpka, Ala.

## Look Here!

Do you need queens? the purest and best. If so, we are prepared by return mail to ship the 3 band and golden Italians, and silver gray Carniolans, untested, warranted purely mated, for 50c; tested, 75c; breeders, \$2.25.

JUDGE E. Y. TERRAL & CO., Cameron, Texas.

**BEES QUEENS**  
Smokers, Sections,  
Comb Foundation,  
And all Apiarian Supplies  
cheap. Send for  
catalog free.  
E. T. FLANAGAN, Belleville, Ill.

## Untested Italian Queens.

Queens ready to mail, either golden or dark queens from select stock, at 65 cents each;  $\frac{1}{2}$  dozen, \$3.50; dozen, \$6.50; two or more dozen at \$6.00 per dozen. Tested queens, 75 cents each.

W. A. COMPTON, Lynnville, Tenn.

**QUEENS.** Either 3 or 5 banded, 60 cents each; 6 for \$3.00. Nuclei and supplies cheap.  
CHAS. H. THIES, Steeleville, Ill.

## Queens,

Either Golden or Imported by return mail. Untested, 75c; Tested, \$1.00; Breeders, \$2.00. None better.

W. H. LAWS, Lavaca, Ark.

Please mention this paper.

## IF YOU WANT BEES

that will just "roll" in the honey, and that are wonderful red-clover workers, also gentle to handle and exceedingly hardy, then try **MOORE'S STRAIN OF ITALIANS**, the result of 18 years of careful breeding.

Warranted queens, \$1.00 each; 3 for \$2.50. Safe arrival and satisfaction guaranteed. Circular free. Those who have never dealt with me I refer to A. I. Root, who has purchased of me over 800 queens.

J. P. Moore, Morgan, Pendleton Co., Ky.

## What More?

GUARANTEED

Queens from best working stock.  
Reared by best methods.  
Cells and queens selected.  
Poor queens replaced free.  
20 years' experience—7 as a q. breeder.  
75c; six, \$3.50; twelve, \$6.50.  
Promptness.  
Safe arrival.  
Free catalogue.

J. B. CASE, Port Orange, Fla.

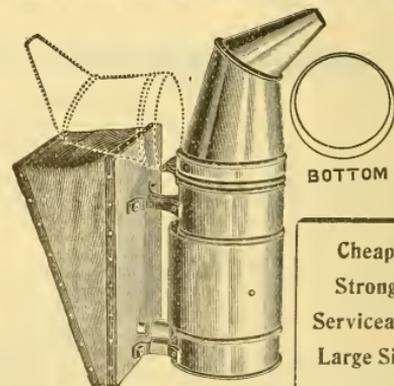

## QUEENS BY RETURN MAIL.

Daughters of best imported queen mother, warranted purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded. L. H. ROBEY, Worthington, W. Va.

**BIG WONDER!** The Smoke Engine goes without puffing; burns in the center; heats only the top; burns chips without drizzle; makes all the smoke wanted, without work; the best bee-smoker ever made; doesn't tip over.  
T. F. BINGHAM, Farwell, Mich.

**QUEENS,** Pure Italians, 3 or 5 banded, tested, 75 cts.; untested, 50 cts. I have 500 nuclei. Can send queens by return mail.  
DANIEL WURTH, Falmouth, Rush Co., Ind.

## The New Corneil Smoker.

Cheap,  
Strong,  
Serviceable,  
Large Size.

**JUST THE THING** for those who want a first-class smoker at a medium price. Size of cup,  $3\frac{1}{4}$  inches; curved nozzle, hinged so as to swing back; legs of malleable iron, secured by bolts. The blast is the well-known Corneil principle. Weight of smoker, only 20 ounces.

Price \$1.00, postpaid, or 75c if sent by express or freight with other goods.

THE A. I. ROOT COMPANY,  
MEDINA, OHIO.

## Send Your Beeswax

to M. H. HUNT, Bell Branch, Mich.,

and have it made into foundation. It will cost you only 12½¢ per lb. for thin surplus, and 15¢ for extra-thin light brood; 10¢, medium brood, or heavy, etc. A carload of Root's goods at bottom prices. Let me quote you prices, wholesale or retail. Large free price list full of information.

In writing advertisers please mention GLEANINGS.

**Orders filled by return mail or freight for A. I. Root Co's supplies, our choice strain Italian queens; one, two, and three frame nuclei. If you want good goods at low prices and in a hurry, send us your orders. 36 page catalog free.**

**JOHN NEBEL & SON, High Hill, Mo.**

## Pure Italian Queens.

Fifty cents each. Warranted first-class. No black bees here, and no disease. Safe arrival guaranteed.

**W. C. GATHRIGHT, Dona Ana, New Mex.**

**FOR SALE.—75 Colonies of Italian Bees,** in eight-frame Langstroth hives. Price \$4 to \$4.50 per colony.

Discount on five or more colonies. **L. Vandereike, Lake Mills, Jefferson Co., Wis.**

**Italian Queens,** either golden beauties or 3-banded imported stock. Tested, \$1.00 each; untested, 70c each; half dozen, \$4.00. One queen to new customer, 65c. **P. O. M. O. Office, Lavaca, Ark.**

**E. A. SEELEY, Bloomer, Ark.**

## Second-hand Bicycles.

One Remington Racer (made by the Remington Arms Co.), weight 20 lbs., 14-in. tubing; nearly as good as new, and listing \$110.00. We offer for \$45.00.

One second-hand Victor, '95 pattern; wood rims; wood handle-bars; Morgan & Wright tires. Sold originally for \$100.00. We offer for \$25.00. It is in good riding condition, having been overhauled in our bicycle-repair shop.

One ladies' Century, used but little, wood rims, 26 inch wheels, Morgan & Wright tires; weight 26 lbs. We offer for only \$20.00. This is a bargain.

Wax at market price will be accepted in place of cash.

**THE A. I. ROOT CO., Medina, O.**

## Wants and Exchange Department.

**WANTED.**—To exchange for any thing useful, St. Bernard puppies at greatly reduced prices; also pure-bred Poland-China hogs and Pekin ducks. **W. W. PREVEY, Elroy, Wis.**

**WANTED.**—To exchange single-queen World type-writer (good as new); also hybrid bees in full colony, for extracted honey or offers. **A. W. GARDNER, Centreville, Mich.**

**WANTED.**—To exchange three 100-gallon heavy tin tanks—improved honey-faucet, four hands, worth \$5.00—for extracted honey. **WM. A. SELSER, 10 Vine St., Phila., Pa.**

**WANTED.**—To exchange Pekin ducks or eggs for Italian queens, African geese or offers. **JOHN BURR, Braceyville, Ill.**

## KIND WORDS FROM OUR CUSTOMERS

We never had such a call for the Root goods as we have this season. Every body praises them, and we are nearly a carload of goods ahead of our sales from the Philadelphia branch over last season. The honey crop is very promising. **WM. A. SELSER, Philadelphia, May 19.**

I think your Home talks and Notes of Travel are excellent; and exposure of advertisements that only our best people of their hard earnings are all right. **La Fayette, Ind., May 24. STEPHEN W. BRADY.**

I received the books all right, for which accept my sincere thanks. I would say that I would not take double what they cost, and be without them. I was a little surprised, though, when I received your letter yesterday returning the small amount of five cents. Now, please, brother, don't do so any more. If I should order any thing and send a few cents more than the regular price, just keep it and don't go to spending half the amount to return it. **Paducah, Ky. D. R. SMALLEY.**

Bees in Texas are just booming. The whole country seems flooded with honey. They are swarming more than I ever saw before. We are using the Langstroth hive, but we have decided to make a change. We shall try the Dovetailed. I think it the most complete hive I ever saw. Bee culture is coming to the front just now in Texas. The people are more interested in the line of bee-keeping than ever before. **G. H. REED.**

**Boyd, Tex., May 14.**

I received the A B C book. Thanks for the same. I have read "Langstroth on the Hive and Honey-bee," and also Langstroth as revised by the Dadants; also King's "Bee-keeper's Text-book," and many lesser works. I think the bee-keeping world owes A. I. Root and son quite a debt for their able work. I want to thank Mr. Weed for his great improvement in comb foundation. The foundation I got this spring works very nicely. I shall be pleased to send to you for any thing I may want in your line. **Cuba, Kan., May 15. WM. H. EAGERTY.**

MILLIONS OF DOLLARS IN "APPROPRIATIONS," AND CORN 10 CTS. A BUSHEL.

*Dear old Friend:*—I write to say how pleased I am that in GLEANINGS, p. 296, you have at last admitted there is something wrong in this United States. It has taken you some years to see it; but I don't wonder; such men as I am have kept you busy. But I can just say, if you had sold honey, strawberries, and eggs for a living, you would have had your eyes opened long ago to that fact. Reduce a community so low that they must live on potatoes and salt, and they will not buy much honey, or clothing either for that matter. **ROBT. B. LANCASTER.**

**Hagerman, Idaho.**

A KIND WORD OF WARNING FROM SOME SAD-HEARTED FRIENDS.

*Mr. Root:*—Last Wednesday, the 19th, right after breakfast, my wife took our little baby boy off his chair to let him play in the yard. He then followed one of the boys out of the lot gate and wandered up the road to a railroad-crossing. A Wabash freight train came along at full speed and ran over the poor child and killed him almost instantly. This happened a little after 7 A.M., while I was at work in the apiary. I tell you it was a shock for us. It happened all in about ten minutes. He would have been 20 months old June 4. He was our beloved baby boy. His name was Henry Frederick Werner. **Edwardsville, Ill., May 31. LOUIS WERNER.**

Dear brother and sister, we all try to sympathize with you; but I suppose none but those who have been through a similar trial can realize what you must suffer. Your warning may, however, do us all good. We live almost as near the railroad as you do, and we have had the same trials with our two grandchildren. Finally we made a little fence of wire netting to keep them within bounds until they were old enough so the danger could be explained to them. The netting costs but little, and with some sharp oak stakes it can be put up in a few minutes; and even now our little granddaughter, just about the age of your lost one, has to be restrained by a gate on the porch, which she can neither open nor climb over. Those who live near railways should be exceedingly careful. As soon as the little one is old enough to understand, it should be warned again and again, until it is made to comprehend the terrible results that may occur from wand-ring away. May the great God above give you consolation and help in this your great trouble.

**BUY DIRECT**

and pay but one profit. Our assortment is one of the best and most complete in

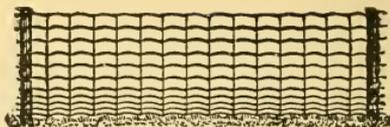

**FRUIT and ORNAMENTAL TREES, SHRUBS, PLANTS, ROSES, VINES, BULBS, SEEDS**

Rarest new, choicest old. Send for our catalogue to-day; it tells it all; an elegant book, 168 pages, magazine size, profusely illustrated, free.

## Honey Column.

## CITY MARKETS.

**NEW YORK.—Honey.**—The demand for honey for the last few weeks has fallen off quite a little. Supply here is rather light; some call for buckwheat comb honey; quite a little call for fancy white-clover comb honey. Beeswax is held stronger, market has advanced within the last week, supply here is light. Considerable demand. Fancy white honey, 10c; No. 1 white, 9c; fancy amber, 8c; No. 1 amber, 7c; fancy dark, 7c; No. 1 dark, 6c. White extracted, 5½c; amber, 4½c; dark, 3¼@3½. Beeswax, 26¼@27¼c

FRANCIS H. LEGGETT & Co.,

West Broadway, Franklin and Varick Sts.

May 29.

**CHICAGO.—Honey.**—Fancy white, 13; No. 1, white, 11; fancy amber, 9@10; No. 1 amber, 7; fancy dark, 8@9; No. 1 dark, 7; white extracted, 5@7; amber, 5@6; dark, 4@4½; beeswax, 27. Choice comb honey would sell freely at top quotation, as market is bare.

R. A. BURNETT & Co.,

163 So. Water St., Chicago, Ill.

May 19.

**MILWAUKEE.—Honey.**—Fancy white, 12@14; No. 1 white, 11@12; fancy amber, 10@11; No. 1 amber, 9@10; white extracted, 6@7; amber, 5@5½; dark, 4@5; beeswax, 26@27. The trade in honey since our last has been dragging, and demand fallen off somewhat. Our supply of choice quality is not large, and think will all be wanted before new crop. The common grades of comb will be the last to dispose of. Hence the moral, improve the quality to a perfect degree, and better sales will follow and better values will accrue.

A. V. BISHOP & Co.,

May 19. Milwaukee, Wis.

**ST. LOUIS.—Honey.**—Fancy white, 12@13; No. 1 white, 11@12; fancy amber, 10@10½; white extracted, in bbls., 4½; in cans, 5; amber, in bbls., 4; in cans, 4½; dark, 3½@4, in bbls.; beeswax, 24½@25. The demand for honey is and will be light from now to the first of October. Bakers and candy-factories not using any this season of the year, and they consume most of our extra stock.

WESTCOTT COMMISSION CO.,

213 Market St., St. Louis, Mo.

May 20.

**DENVER.—Honey.**—Fancy white, 11; No. 1 white, 10; fancy amber, 9; white extracted, 6; amber, 5; beeswax, 25. We are having an unusual demand for our brand of extracted honey. It has been well advertised of late, and our customers know a good article when they use it. There are several brands of honey shipped to our market that are not pure, but we believe all Colorado honey on our market to be pure. The great trouble we have to contend with in this dry climate is granulation. We are looking for a good crop of honey this season.

R. K. & J. C. FRISBEE,

May 22. Lock Box 1014, Denver, Col.

**NEW YORK.—Honey.**—Our market is in good shape—the old crop well cleaned up, both comb and extracted. New crop extracted is arriving from the South, and in fairly good demand at 50@52 per gallon for average common, and 55@60 per gallon for better grades. Beeswax rather quiet at 26@27.

HILDRETH BROS. & SEGELKEN,

120-122 W. Broadway, New York.

May 20.

**CLEVELAND.—Honey.**—Fancy white, 12@12½; No. 1 white, 10@11; fancy amber, 8; fancy dark, 7.

A. B. WILLIAMS & Co.,

May 25. 80-82 Broadway, Cleveland, O.

**KANSAS CITY.—Honey.**—Fancy white, 12@13; No. 1 white, 11@12; fancy amber, 10@11; No. 1 amber, 8@10; fancy dark, 8@9; No. 1 dark, 8; white extracted, 5@5½; amber, 4½@5; dark, 3½@4; beeswax, 25.

May 20.

423 Walnut, Kansas City, Mo.

**BOSTON.—Honey.**—Fancy white, 13; No. 1, 11@12; white extracted, 7@8; amber, 5@6; beeswax, 25@26. Our market is without change as to price, but we note a lighter demand natural to the warm weather.

E. B. BLAKE & Co.,

May 19. 57 Chatham St., Boston, Mass.

**DETROIT.—Honey.**—Fancy white, 10@12; No. 1 white, 10@11; fancy amber, 8@9; No. 1 amber, 7@8; white extracted, 5@6; amber, 4@5; beeswax, 25@26. Dark comb not much called for, and what there is in sight is not attractive, and buyers of it can make the prices.

M. H. HUNT,

May 20. Bell Branch, Mich.

**SAN FRANCISCO.—Honey.**—Fancy white, 10; No. 1 white, 9; fancy amber, 7; No. 1 amber, 6; fancy dark, 5; No. 1 dark, 4; white extracted, 5; amber, 4; dark, 2; beeswax, 24. New honey of very fine quality is coming in the market. The crop will be a good one, but less than expected three weeks ago. Looked for late rains did not come.

HENRY SCHACHT,

May 14. San Francisco, Cal.

**CINCINNATI.—Honey.**—No. 1 white, 10@13; No. 1 dark, 8@10; white extracted, 5@6; amber, 4@5; dark, 3¼@4; beeswax, 22@25.

CHAS. F. MUTH & SON,

May 18. Cincinnati, O.

**COLUMBUS.—Honey.**—Fancy white, 12@12½; No. 1 white, 11; fancy amber, 8. Strawberries are now arriving so freely that honey is slow sale. Advise no shipments without direct communication with us.

THE COLUMBUS COM. & STORAGE CO.,

May 22. 409-413 N. High St., Columbus, O.

**MINNEAPOLIS.—Honey.**—Fancy white, 12@14; No. 1 white, 11@13; fancy amber, 10@12; No. 1 amber, 9@10; fancy dark, 8@9; No. 1 dark, 7@8; white extracted, 6@7; amber, 5@6; dark, 4½@5½; beeswax, 25@27. Comb honey nominal. Movement very light and will probably continue so during warm weather. Extracted steadily demand, moving on new water white at full quotations.

S. H. HALL & Co.,

May 20. Minneapolis, Minn.

**PHILADELPHIA.—Honey.**—White extracted, 5@5½; amber, 4@4½; dark, 3½@4; beeswax, 25. No comb honey in this market but odds and ends. Nobody wants comb honey now. Considerable call for extracted. Beeswax in constant demand.

WM. A. SELSER,

May 21. 10 Vine St., Philadelphia, Pa.

**FOR SALE.**—(Fancy sections) mango honey in 30-lb. cases. Cash offers wanted, f. o. b. here.

H. PRICE WILLIAMS, Miami, Florida.

## HALF PRICE.

After June 10th we sell eggs from all our yards at HALF PRICE (\$1 per 15). Eggs will be from our best pens, and handled with the same care early orders receive. Our breeds:

Barred & White Pl. Rocks, Lt. Brahms, Langshans, Bl. Cochins, White Wyandots, Brown & Buff Leghorns, Pekin Ducks.

Our stock will surely please you; order now.

## POULTRY SUPPLIES.

We are America's Headquarters. Biggest Stock, Lowest Prices, Quick Shipments.

NISSLY'S POULTRY ANNUAL and catalogue of "EVERYTHING FOR THE POULTRY YARD" is a book of 80 6x9 pages, finely illustrated and full of information. The book is FREE TO ALL, but we request a 2c stamp for postage.

GEO. J. NISSLY, Saline, Mich.

# What Has Been Told Lately

In the *Bee-keepers' Review*? did you ask? Well, in the Jan. issue Mr. Aspinwall explained a simple plan whereby the mating of queens at the home yard may be secured with almost *absolute certainty*. R. L. Taylor, in the February issue, describes an experiment made to determine if honey stored in the super of a foul-broody colony was infected with the germs of foul brood. In the March number, Isaac Lundy told "How to Get Drawn Combs right in the Sections, and Secure Comb Honey at the same Time." In the April issue, R. L. Taylor tells at what a high temperature he kept his bee-cellar last winter, and the results. The June issue contains a long article from Mr. Lundy, explaining his methods, and giving the details of a plan whereby he secures drawn combs during the white-honey harvest. Of course, there are other articles, editorial comments, extracts, notes from foreign bee-journals, Hasty's "View of Current Bee Literature," etc.

The *Review* is \$1.00 a year; but for the sake of getting new subscribers I am offering it for 1897, and 1000 first-class sections, for only \$2.50; or the *Review* and a Bingham Conqueror smoker for \$1.75; or the *Review* and a fine tested Italian queen for only \$1.50.

W. Z. HUTCHINSON, Flint, Mich.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4-inch Smoke Engine too large. January 27, 1897. Truly, W. H. EAGERTY, Cuba, Kansas.

Bingham & Hetherington Uncapping-knife.

T. F. BINGHAM, Farwell, Michigan.

# A Penny Saved is a Penny Earned.

Yes, it's better than that, for the saved penny you don't have to earn twice. Well, the *Weekly American Bee Journal* will help you save your pennies. It is a real money-saver to the bee-keeper who will read and practice its teaching. The regular price is \$1.00 a year, or only about two cents per copy. But in order that new readers may give it a trial we will send it for only 50 cents from the time we receive your subscription to the end of 1897. Now, the sooner you send the half dollar, the more copies you will receive. Send 1c stamps if more convenient. Sample copy free.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

No. 12.

**STRAY STRAWS**  
 FROM DR. C. C. MILLER.

YELLOW SWEET CLOVER blooms about two weeks before white sweet clover, according to J. L. Gandy, in *A. B. J.*

GARGLE for sore throat.—Salicylic acid and borax, one-half drachm each; honey, one ounce; water, eight ounces.

TO TAKE GREASE out of cloth.—Take 8 parts alcohol, 6 parts honey, 5 parts soap, 5 parts water. Wet the cloth with this solution and rub lively. Keep the mixture well corked.—*Mode Francaise.*

WHILE IT'S TRUE that stoves may have done more harm than good in bee-cellars, it needn't be so. You can do mischief with almost any good thing by using it wrongly. But an oil-stove isn't a good thing.

"INSIDE FURNITURE" is all right for what the hive contains before bees have ever occupied it, but I think what R. Wilkin wants is a term to include bees, comb, and brood. [What does R. Wilkin want another term for?—Ed.]

"WOULD YOU USE sections with foundation put in them two years ago?" is asked in *A. B. J.* Of the 23 repliers, only three say no. Several advise warming in sun before using. I wonder if they won't be warmed by the bees sufficiently.

IN THE STATEMENT, quoted p. 423, that "the nectar gathered by the bee is a secretion in which we may expect to find the essential virtues of the plant from which it is obtained," I wonder if imagination has not been allowed considerable play.

ANOTHER DRAWBACK to the plan of fastening queens in hives that A. Getaz might have added, p. 413, is that sometimes, after they have swarmed times enough, several swarms will settle on a tree together, and sulk all day. I think they'll do it without a queen.

AN EDITORIAL in *A. B. J.* shows a strong leaning on the part of the editor toward the view that every beginner in bee-keeping should have a text-book. If I couldn't have both a bee-book and a bee-journal I'd get the book first, and then pawn my watch for a journal.

"DON'T TRY to go too fast into bee-keeping. Better grow into it," says Editor York. Sound advice. [That is true; but many a man does not believe it in actual practice; or if he does, he shut his eyes and jumps—all the more reason why such folks should be made to open their eyes.—Ed.]

PROF. COOK thinks the old Union ought to make a big fight against adulteration in California. He says, in *A. B. J.*, "The Union has got to do this, or something akin to it, or else it will be dissolved and possibly merged into the other organization." [Prof. Cook is right.—Ed.]

FOR YEARS I've kept my bees in two cellars. I thought they had better air than in one. But it's less trouble to have all in one cellar, so last winter I put all together; wintered splendidly, and had fire only once, just for five days. I think G. C. Greiner is right in wanting a cool cellar filled up. [A good point. Those who cellar their bees next year would do well to bear it in mind.—Ed.]

DOOLITTLE, p. 414, has given an unusually full collection of plans for managing after-swarms, and he might have added two others. Except for the trouble, there's no better way than the old box-hive plan of returning the swarm as often as it issues. One of the best plans is to hive the swarm on the old stand; set the parent colony beside it, then set the parent on the new stand a week later.

A COMMON OPINION seems to be that, when you take away a queen, the bees in their eagerness to replace her make use of larvæ so old that a good queen can not result. I'm skeptical. In hundreds of cases that I have observed, the queen rarely emerges before the eleventh

day from removal of queen, making the larva only one or two days old at time of queen's removal. [You are right, doctor, according to my experience.—Ed.]

I HAVE ONE of the late smokers with grooved bellows-boards, and as yet see no objection to it. On the other hand it's refreshing to weary muscles to handle it, and the grooves will save the smoker many a fall. [The new grooves in the boards are a great comfort, and we shall adopt them in all our smokers as soon as possible. They cost but little and are a great convenience, especially where one's hands are sticky with honey.—Ed.]

TO THE QUESTION, whether it's best to use drawn foundation in sections, repliers in *A. B. J.* assume more or less of a "don't know" attitude, with a preponderance toward giving it a fair show. [Even those who answered unfavorably, in some instances at least, would have given a different answer had they seen the article itself. A case in point is that of Mr. McEvoy, mentioned on page 456.—Ed.]

THE *American Bee Journal* and *Canadian Bee Journal* agree that they are not called on to help every new enterprise in the way of a bee journal; but *Review* thinks it would be impolite to refuse a free ad. to an intending rival. [GLEANINGS takes middle ground. It believes in recognizing real merit, from whatever source it may come. At the same time, it also believes that possibly more harm than good is sometimes done by recognizing journals which are not yet out of their swaddling-clothes.—Ed.]

CURIOUS how persistently some passages of Scripture are incorrectly quoted. There's that one on p. 414, "A wayfaring man though a fool need not err therein." Just half of those ten words are like those in *Isalah*, which reads, "The wayfaring men, though fools, shall not err therein." [What harm is done, providing we get the *idea*, the essence of the truth, and live up to it? I am one of those unfortunate persons who can not quote Scripture correctly to save my neck; but I can generally remember the *idea*, and that is worth tenfold more than the exact language without the thought. It is better, I grant, to remember both if one can.—Ed.]

I'M SORRY TO SAY that, although my horses eat a little sweet clover green, they don't like it as well as grass. It seems to go better dry than green. [For policy's sake, doctor, perhaps I ought not to publish the above; but I am going to give it a place all the same. Let us always have the truth, no matter which way it cuts. Did you ever taste the leaves of sweet clover then those of *other* clovers? You will find that those of sweet clover have a bitter taste, or at least a pungent weedy flavor that the others do not have. If the "likes" of horses is similar to mine I do not know that I blame the

horses for manifesting their preference. The flavor of the leaves is a little like the taste of sweet-clover honey. This, while it is nice white honey, and brings a good price, can not rank with the honey of other clovers. But all the same we should remember that sweet clover is the only fodder that will grow in some parts of the west, and as such is an invaluable crop.—Ed.]

A WRITER in *A. B. J.* condemns the bee-space in bee-hives as causing a loss of heat, and in a subsequent number W. Z. Hutchinson comes vigorously to its defense, thinking there can be no great loss of heat if it only escapes from one part of the hive to another. Not much danger the bee-space will be given up. [I should like to see the man who could be really good-natured all the time, and get along successfully without bee-spaces in hive-construction. There is hardly a single feature in modern apiculture, to my notion, that is more essential. We could almost as soon dispense with movable frames.—Ed.]

IF YOU HAVEN'T yet seen crimson clover, it would make you open your eyes to see the beauty of my patch now in bloom. It's well worth a place in the front yard. [A big field of it looks better, doctor. In fact, my eyes are now resting on one within a stone's throw. It's the town talk now, and, oh how the bees do hum on it! I verily believe a given acreage of crimson clover will furnish more nectar than any other plant. It is a more rapid grower than any other clover, yields honey before any other, has larger heads than the white, and short flowrets. Surely a great future is in prospect for crimson clover, both for the farmer and for the bee-keeper. Say a good word for it wherever you can, brethren—at conventions, anywhere; and if you do not succeed in growing it, learn how. We make it grow every year.—Ed.]

I FOLLOWED you with much interest, friend A. I., on page 427, as you watched all night for the frost, and felt quite relieved when you got through safely without the expense of moving those 150 sashes; but I couldn't help wondering if your wife didn't think your broken night's rest fooling around in the chill night air was paying just a little too much for all you saved. [Why, dear doctor, you seem to forget that I take a nap every forenoon and another nap every afternoon; so if my sleep is cut short a little I just make the afternoon or forenoon nap a little longer. See? Another thing, I am usually awake by daylight, or a little after, the year round. I do not always get up, of course, as soon as it is light, but it is not very much of a task for me to get up as soon as I can see, if any thing happens to require it; and I make it up somewhere about 10 or 11 o'clock, as I have mentioned.—A. I. R.]

By R. C. Atkin.

#### MARKETING HONEY.

In a preceding article, on page 407, I discussed this question, showing that there was no *regular package* or method of getting extracted honey on the market in shape to retail. We have the wholesale packages that are all right for the bakers' and manufacturers' trade; but what we want is a strictly retail package—one that can be both wholesaled and retailed. I suggested that the honey be canned as fruit and vegetables, crated as they are, then it can go through the regular trade channels. If we do this, there is the

#### CANDYING QUESTION.

I have been making it a practice to sell all my extracted honey liquid, both wholesale and retail, except to those who wanted it otherwise, or who were prepared to liquefy for themselves when they wished it so. I have had local customers who would take it as quickly candied as liquid, and some who preferred it candied. There are two main reasons for putting it out liquid; viz.: If in wholesale package, the purchaser will want it so he can draw it out for retail. Few who buy at wholesale are prepared to liquefy, and neither the dealer nor consumer, as a rule, knows how to *properly* liquefy. It would not be a hard matter to educate the dealers to do the liquefying; but suppose they do melt it, it will candy again if not soon used, so, after all, the consumer has to liquefy—rather *reliquefy*. If, then, the consumer must liquefy, why not do away with the whole matter, and, just as soon as the honey is extracted, put it in small cans of, say, 1, 3, or 5 pound sizes—or, possibly, better only two sizes, say 3 and 5 pound? Let it candy, and let the consumer follow printed instructions and liquefy for himself; or, if he prefers, use it in the candied state. This would save the darkening and flavor-killing process of so many meltfngs. Just give the people a chance to buy honey at or near the price of other sweets of similar grade, and they will soon learn to do the melting. If only she had or could get it, would not every housewife soon learn how to prepare honey? It is an insult to the intelligence of our women to say that they would not learn to liquefy honey when every can has plain instructions on it. They will learn it as they learn how to prepare the many kinds of food products. If anybody doubts this, just let

him establish a trade on honey in candied form; *always* have the article at regular trading-places, at prices that will compete with other sweets of same grade, and I am sure he will find customers; but rest assured that, if you are constantly changing size, style, and cost of package, and do not keep the goods always on hand to be had when called for, you will soon lose your trade.

Mr. J. L. Strong, of Clarinda, Ia., who has been for many years producing honey there, tells me that, by a little instruction now and then to his customers, they soon begin to call for the candied honey, many preferring to use it that way. No, no, friends; the people are not so slow to use our products as we are to put it in proper shape and get it to them. They want it so they can buy it at the stores with their other purchases of groceries, and we must put it there.

Last year a number of Colorado apiarists talked very seriously of organizing a company and buying honey-cans in car lots, putting up our own and neighbors' honey. In correspondence with one of the most extensive honey-dealers in Chicago they said they would not take the responsibility of selling such goods; but if I would make a start and put up my honey that way they would try to introduce it. The plan we had in mind was to organize and get a registered trade-mark, put the goods out under an association guarantee, and that all goods should be standard grade. On account of failure of crop, and the heavy loss of bees from some unknown cause, the matter was dropped. I am very much interested to know the outcome of the efforts of the California association. Very few men produce in quantity to undertake any thing of the kind; but by organized effort there could be a great change wrought, and much good done. Let me here repeat what I said in the previous part of this discussion, that there is not honey enough on the market to make it an object for people to invest in honey-depots or packing-houses, or to get the product properly before the public.

#### HOME MARKETS.

Last year—1896—I had a very light crop, amounting to two tons or less. As I wanted to get off on our tour in the wagon, I wanted to dispose of the honey as quickly as possible. I found the quotations were from 5 to 7 cents, delivered, in the wholesale markets. Freight to Denver are about  $\frac{1}{2}$  cent, and to Chicago about \$1.90 per 100 lbs. If I sent the honey to these markets, and took what was left after freights and commission were out, I should have only 4 or 5 cents, to say nothing of cost of cans, and the risk. If I left the honey for some one else to look after, the liquefying and bother would eat up a large per cent of it. I had sold much more honey the previous year than my present crop, right at the honey-house, at from

6 to 8 cents. So I said if I must sell to Denver or Chicago at 6 or 7 cents less freights and commissions, I would let the people at home have it just as cheaply as some commission man. I then advertised that I would sell from the honey-house in any amount at 6 cents if purchaser brought his vessel; but if I furnished the vessel I would charge its cost extra. You see, the poor family that could not buy 50 pounds could get 5 or 10 pounds at the same rate as the more wealthy. I sold the crop out in a very little while, it going about as fast as I could extract and get it ready.

I suppose many would tell me that I was ruining prices by putting the price so low. Let me explain that. If I had been staying there right along I could have sold the crop during the year at about 8 cents. The reason I say 8 cents is because sugar can be had at about 6 cents, and makes a very good syrup; and if I get too much above the price of sugar I should lose the trade of all but those who will pay more for the honey because they like honey better than sugar syrup; but to those who must economize, the cheaper sweet would take the preference. In order to get as much as possible into the poorer families, and to insure sale, I put the price at only 6 cents, which was better than 7 cents in the city markets, because it was net price. In fair to good seasons there is much more honey produced in my locality than the local trade will take. I have sold quite a little to peddlers who go to the mountains, and to localities where there is no irrigation. The question practically is, whether I shall sell in the home market as cheaply as in the cities. If I make the local price about a retailer's commission above what the honey would bring at wholesale I have not damaged myself, and have marketed more of the crop at home than I could have done at higher prices. If the local demand is greater than the production, and honey is shipped in to supply the deficit, then it is proper that our local product be sold at the price the foreign goods must bring to pay first cost, freights, and commissions. As my locality does not import any honey, but, on the other hand, I must export my surplus over local demand, it is but just and right that I put the price to the local trade just enough above wholesale to pay me for dealing it out. This will increase the local demand, and in so far relieve the pressure on city markets.

That our local markets are not properly worked, I am sure. We must "introduce" our goods; and, when once we have a trade, *keep it supplied*. Remember that the dealer who gets the business is the one who keeps the goods wanted, and at reasonable prices. Will not some of our men of means take up the matter of packing honey and establish houses in all producing districts to handle the surplus prod-

uct in those fields? We *must* have something of this kind, regular standard packages, and our goods put before the people in a systematic way, or we must be content to sell locally, and raise or lower the price as we may have a small or large crop. These are my conclusions after studying the problem for several years.

Loveland, Col.

[I question whether we could get the general public to look with very much favor on a package of extracted honey that is candied—one that must be brought to a liquid condition before it is consumed. However that may be, I think you are exactly right in urging the importance of a uniform package; and if some organization does take hold of it, the A. I. Root Co. will. If there is a demand for it, we will place on sale at our various branch offices and depots fruit-cans of a standard size, in car lots; but before we can go into any enterprise as gigantic as this, we must have the assurance that bee-keepers generally would accept the standard can used by all fruit-men. In the mean time we solicit the opinions of the brethren. The standard fruit-can package in question is the one described in our last issue, page 469. It has no patent fastening or screw-top, but is simply a common fruit-can that is sealed by soldering. For this reason it should be put on the market considerably below the cost of ordinary self-sealing packages of equal capacity. We are at present writing for prices.—Ed.]

---

### HOME-MADE VS. FACTORY-MADE FOUNDATION.

SECTION-PRESSES, ETC.: THE EDITOR'S STATEMENTS CRITICISED.

By F. L. Thompson.

On page 318 a footnote says, speaking of the Rietsche press, "At present prices of foundation, no bee-keeper could afford to make his own, especially if he could turn out only 150 sheets an hour."

Beeswax in Cleveland and Cincinnati is quoted highest at 25 cents a pound in that issue of GLEANINGS. Suppose one makes his foundation as thin as 8 L. sheets to the pound. This grade, when bought, costs 42 cents a pound in quantity. By making one's own foundation, 17 cents a pound is saved, and 150 sheets of foundation an hour means 18½ pounds per hour worked, or \$3.14½ per hour, or about \$25.00 per day saved—say \$20.00 net, so as to take account of the fuel, lubricant, interest on value of all articles used, etc. If I could do one quarter as well, and save \$5.00 a day, I should feel as if I were making money. And yet, "no bee-keeper could afford to make his own!" Mr. Editor, you could not have been thinking of the bee-keeper, but of the big supply-dealer, when you wrote those words. What is "altogether too slow" for the latter is extremely fast for the former. Consider, too, that the press (or, rather, mold) is very easily worked, does good work, and turns even small portions of wax to account. (It has been improved of late). It is

hard to understand why it would not be a most profitable investment for the *bee-keeper*—not the supply-dealer. It is true, its product soon becomes brittle if stored away; but its other advantages completely destroy this objection; for if the foundation made from it is used at once it is not brittle; and when the machine is right at hand, and works up even small quantities with ease, it pays to make foundation only as wanted.

I must also question the footnote on page 320, relating to the use of combined machines for folding sections and fastening foundation, saying, "We find the two are more rapid, simpler, and cheaper than any combined machine we have ever operated." □ If you find it so, that simply proves that your operatives are accustomed to separate machines. Let a man work long at one thing, by the piece, and he inevitably acquires great dexterity. Let him then try to accomplish the same thing by another method, even a superior one, and a few hours' or a day's practice is entirely inadequate to enable him to equal the speed of the method which has become automatic with him by long practice. But is that a fair test? Of course, not. Equal familiarity (so far as that has a bearing on speed) with both methods is absolutely necessary before pronouncing judgment. I have never used the Daisy foundation-fastener, but have one before me as I write, also specimens of its work. On comparing it with the foundation-fastening portion of the machine which I use, I find it impossible to believe that it can do quicker or better work, if as good. But with the machine I use, there is the distinct advantage that one does not have to handle the sections twice in their passage from the crate to the super. There is no getting around this; and when both portions of the machine do just as good and as fast work, separately, as the separate machines, it follows with mathematical certainty that, when one handling of the sections is saved, the combined machine must make better time when there is the *same degree* of familiarity with the combined and the separate machines. Of course, one of your crack workmen might beat me with the Daisy and the Hubbard, or, with a few hours' test of the combined machine, might not equal his record with the two former; but such comparisons would be obviously unfair. Little influences which are hard to describe hamper one's ability in changing from one machine to another. A good performer on the organ can not do as well on the piano unless he has practiced the piano also, and *vice versa*. I can do faster work with the combined machine (the Rauffuss, which, by the way, you have never tried) than with the separate machines I have tried, and that settles it for me; and I feel sure the average bee-keeper, approaching the separate and combined machines with the same degree

of practice or non-practice, will have the same experience, and vote the latter ahead.

#### THE GRANULATION OF ALFALFA HONEY.

On page 321 it is claimed that alfalfa extracted honey does not granulate on account of locality, but on account of lack of "body." This seems a natural inference from the (somewhat meager) circumstances given; but I know the writer is mistaken. There are plenty of progressive bee-keepers in Colorado, though he seems to doubt it. That "body" depends on the handling is one of the A B C's here, and the handling is as well understood as in any State. I never extract before the cells are completely capped, if I can help it, and am in no particular hurry to extract then, if combs are numerous enough to tier up with. Moreover, I have frequently extracted from combs which have been two months or more over the bees since being capped. The "body" of such honey can hardly be surpassed. It is difficult to extract at all. But this very honey, kept separate in a reasonably warm and dry place, granulated just like the rest—generally sooner, if any thing, perhaps from some admixture of fall honey. Extracted fall honey here granulates much sooner than early honey of the same degree of ripeness (though the early honey is really inferior in body), showing conclusively that something else than handling influences granulation here; and if by "handling" is meant heating as soon as extracted, that also is known here, and practiced by some; but, with a few exceptions, it only delays granulation, and does not prevent it.

This leads me to say that I rather doubt whether Dr. Miller's scheme of draining off the liquid part would work with alfalfa honey, it candies so uniformly, reminding one of solid lard rather than any thing "granulated." I have frequently noticed, though, that some honey in the combs granulates coarsely, here in Montrose Co., as well as around Denver. But such honey is generally, perhaps always, of a golden yellow, and I think is always stored in the latter part of the season, containing a large per cent of something not alfalfa honey.

Montrose, Cal., May 28.

[Your implication, that my statement in reference to the cost of foundation was made on purpose to favor the supply-dealer and not the bee-keeper, is a sort of "left-handed compliment"—that is, if you mean I would be willing to twist the truth for the sake of booming our wax-working department. I shall assume, at all events, that you did not mean to hit as hard as this. I have endeavored, so far as possible, to have the truth come out, let it cut where it may; but when the truth favors *both* the bee-keeper and the supply-dealer, I can not see any harm in giving emphasis to it. I believe that nothing would kill a journal quicker than to have it give one-sided truth, and that favoring some manufacturer. Realizing this, it is our constant purpose to make GLEANINGS give impartially all sides of important questions.

In regard to the point at issue, I think I can show you that you are away off in your figures. You do not say anywhere that you have actually tried the Rietsche press yourself. If you have, it is likely you would have said so. But if you have not tried it, you are basing your argument, not on what you actually *know* from experience, but on what you have read, or what you think would be true concerning the press. You say, "Suppose one makes his foundation as thin as eight L. sheets to the pound." Right here I can not help feeling that you are assuming that that number of sheets can be made with the press in question, for you say, "Suppose," etc. I do not say that this number can not be made under very favorable circumstances, and with a special press; but I do not believe that the average bee-keeper can produce that number of sheets. We have one of the Rietsche presses; and the best we have been able to make so far has been three sheets to the pound, L. size. And *such* foundation!—clumsy, and with a great waste of wax in the bases. With the directions that came with the machine, the manufacturer states that a kilo of wax will make one square meter of foundation. If I figure correctly, this would be the equivalent of  $5\frac{1}{2}$  L. sheets, nearly, to the pound. Is it not reasonable to assume that the manufacturer would place the number of square inches per pound at its highest limit? At any rate, it is altogether improbable that he would put the figure lower than could be secured by the average bee-keeper; yet you "assume" that *eight* L. sheets of foundation could be made per pound on the Rietsche press.

Now, I am going to "suppose," for the fun of it, that three sheets is all that you can make, for, in fact, that is all we have made with our machine. Allowing you a speed of 150 sheets per hour (which I think is altogether improbable), then you will have about 50 lbs. of wax worked up. This, at 25 cts. a pound, would be a total of \$12.50. Allowing you 25 cts. an hour for your time, this would make the 150 sheets of foundation cost \$12.75. That number of sheets of foundation made by a supply-dealer, just as good, and even better, without any unnecessary waste in the bases, and running *eight* sheets to the pound, would, at 42 cts., cost \$7.87; or, in other words, you would be "in the hole" \$4.88 per hour, or \$48.80 per day, to say nothing of the cost of the press itself, and the musing-up of things generally.

Perhaps you will say it is not fair to assume that only three sheets per hour can be made. Well, then, let us assume that five sheets can be made—nearly up to the limit allowed by the manufacturer: then you would make 17 cts. per hour *provided* you could turn out sheets at the rate of 150 per hour, which I very much doubt. But you say it is not fair to compare a less number of sheets per pound from the Rietsche press with the larger number of sheets per pound from the manufacturer. If the dealer's foundation is just exactly as good as and even better than the Rietsche, at the lesser weight, and costs less, I can not see that there is any thing wrong in the comparison.

I did not dispute the figure that 150 sheets could be made per hour, on p. 318, that you refer to. It did not occur to me at that time how many it would make. While an expert might equal it under favorable circumstances, I doubt whether the average bee-keeper could make many more than a sheet every minute. With our press we can't begin to equal even that rate. We had trouble with the sheets sticking to the die-faces, notwithstanding we used several different kinds of lubricant.

The majority of bee-keepers who have used

the modern roller machines, of which we have sold so many, and who are able with them to beat the wax-press all to smithereens in speed, have long since come to the conclusion that it does not pay to make foundation for their own use. It is an art—a trade in itself. If a roller machine can't compete with the large factories, how can an inferior cheap machine? In Germany, bee-keepers can not always be sure of securing pure wax in the foundation procured from supply-dealers in that country, and hence has arisen this demand, I believe, for a cheap machine to make their own foundation of their own beeswax.

With regard to combined section-folders and starter-machines, perhaps you have not had the experience we have. We have carefully tested every machine that has been sent to us; and I have always told our workmen that we desired to have them test the machines carefully; and in every case we found we could operate not only much more rapidly, but do better work with our two machines. All the combined machines I have ever seen take too much physical power to fold the section, and even then they do not do a satisfactory job. The Hubbard machine makes use of a long toggle joint, by means of which great power is secured with a very small expenditure of effort on the part of the operator. Even if the combined machines would do the work more rapidly, we should still prefer the Hubbard on account of the superiority of the work. You admit yourself that you have not tested the Daisy machine, although you have one before you. Perhaps you have not tested the Hubbard. If not, then I can hardly see how you are any more unprejudiced in the matter than we are. Theoretically a combined machine ought to do the work more rapidly; but in actual practice it does not do so—in our hands at least. We have had parties write to us before now, praising the merits of their combined machines, for they could do a certain number per hour—that is, fold and starter the sections. It has been a little amusing when we have compared their figures with those from our two machines, with which we doubled and trebled their best speed. Assuming that the inventors of these different machines were reasonably expert in the use of them, they ought at least to be able to turn out within 75 per cent of the best output of their machine. By giving their machines credit for doing at least 25 per cent more, even then we have in every case been a long way ahead. I do not know whether I have tried the machine you refer to or not—I think not. If you can do better and faster work, I should be very glad to know it. We are constantly looking for the best in apiculture, and should be glad to know more about it.—Ed.]

---

### EXTRACTED HONEY.

HOW WE RUN OUR BEES TO PRODUCE IT.

By F. A. Snell.

Each bee-keeper has his own favorite way, and I will give ours. In the extracting-supers we use the same comb-frames, or those of the same size as used in the brood-chambers. We make it a point to remove from the brood-chambers all frames containing a large amount of drone comb, and put in their place good worker combs. By so doing we have but a small number of drones reared, or not more than desired. These drone combs are used in

the supers. Just before the surplus-honey season opens we look over all these supers and see that no spider-webs or any thing objectionable is present. The bits of comb, if any, are removed, frames are put back in place, and these are ready for the bees. Our queen-excluders are brought from the storeroom. The smoker is lighted; the bees are given a little smoke, the excluders placed over the brood-chambers, and one super or story is put on over an excluder on all colonies to be run for extracted honey that are strong enough to need extra room. Later, as other colonies become more numerous they are given a super each.

Many years ago we practiced equalizing brood to some extent in the spring, with a view to uniformity in strength, but have not done so for about twenty years. We do not believe in pulling down a good colony to help a weaker one, only to save a queen that we may prize. After the honey-flow fairly opens we make it a rule to see what is being done in the supers or colonies not yet having extra room, so that, if more room is needed, it may be given at once, never allowing a shortage of room for storing. In doing so, two objects are desired. One is to discourage swarming from overcrowding; the other, to secure the greatest amount of surplus honey. We run all colonies two and three stories high, or one or two supers on each hive of full-depth combs during good honey-flows. When the shaking-off plan is practiced we have two men in the bee-yard. Extra empty combs are at hand. Man No. 1 opens the top super, or the one with the well-ripened honey; removes the combs and hands them to No. 2, who shakes off the bees at the hive-entrance, brushing off the few remaining ones with a brush made of asparagus-tops; places the honey in an empty hive-body on the cart. The one who opens the hives removes the filled combs and places empty ones on the hives, and stands behind the hives, the other in front. As soon as the bees are shaken off at the hive-entrance he steps back a few feet and puts the combs in the empty story. When the honey from the first hive is on the cart it is run to the honey-room door, and the honey carried in. Man No. 1, after filling the first super with empty combs, shuts up the hive and opens the next hive. This man keeps the bees under control by using a little smoke as needed. The cart is run back to hive No. 2, with a set of empty combs, and so the work proceeds in the yard. The one in the honey-room removes the combs from the filled super, which was placed, when brought in, on a bench about 18 inches high, with two one-inch strips running lengthwise at each side on top, on which the supers are placed, giving room for the fingers in placing and removing under the sides of supers. Three supers single-tier, or six double-tier, can be so placed if it is desired.

The one in the honey-room does the uncapping, extracting, and pours the honey into the large cans or barrels, using a cloth strainer at all times, which excludes all except the honey. We use an uncapping-can in principle like the Dadant. When the apiary has been gone over, third stories are placed on all the stronger colonies. As stated in a former article, I now prefer to use the escapes as there mentioned to the shaking-off as herein described.

To those not experienced, and who have no escapes, the hints here given may be of some value. In a small apiary the bee-keeper can readily do all this work where his time is nearly all devoted to his bees.

The use of a great amount of smoke in handling bees should be avoided. A little at a time is usually sufficient. A great amount of smoke will injure the flavor of the honey. With escapes, very little if any need be blown on the combs when extracting, which is another point in favor of their use.

Milledgeville, Ill.

### BEE-PARALYSIS.

ANOTHER CURE; A GLEAM OF HOPE.

By *Joseph Monnier.*

Last fall my prospects as a bee-keeper were very unsatisfactory by reason of "paralysis" among the bees, nearly my whole apiary being infected. The bees had a greasy appearance, and were dying in front of the hives by thousands, and I thought seriously of giving up the business. So, just before starting for Miami to pass the winter, I doubled up several of the very weakest and left them for all winter in discouragement.

About the first of last March I went to take a look at them, and found about half of the colonies entirely dead, and the others very weak; but I was surprised to see the hives I had doubled up. They were as strong as any I ever saw—had a bright healthy color, and not a sick bee. They were full of honey. This set me to thinking, and I formed this theory:

The bees were loath to kill off their own sick brethren, but killed the sick strangers without mercy, and thus threw off the disease; so I went to work and put two colonies together, where I thought they were too far gone; and where they still had enough bees I simply changed their places, putting No. 1 in the place of No. 2, and No. 2 on the old stand of No. 1. I did this in the middle of the day, when the bees were at work, also shaking some combs of bees before their entrances, so as to mix up thoroughly the bees in both hives. The results were astonishing. They went to work on the sick bees and in a few days I saw a marked improvement; and now my apiary is as healthy as any I ever saw. I have already extracted 550

gallons of honey, besides increasing my bees back to last fall's count. The bees are bright, full of life, and are as cross as any I ever saw. All a hive needs is bees from another colony, to cure themselves. So sure am I of this, that, if I were buying bees now, I would not discount them on account of paralysis. If, as you say, it may come again, let it come. It doesn't take long to apply the remedy; and if you could see my bees now it would be difficult for you to realize the condition they were in only three months ago.

Please let the brothers know of this remedy, and I shall feel myself amply repaid if those who are benefited by it will write me and acknowledge the fact.

Planter, Fla.

[Bee-paralysis has been one of those difficult diseases to cope with, first, because we hardly know what it is; and, second, hitherto no suggested remedy has worked invariably; and all of them, sooner or later, have resulted in failure with nearly every one. But your manner of treatment affords us a gleam of hope, both for what it has done in your case, and because, from a sanitary point of view, it looks reasonable. Good sanitation nowadays means separating the sick from the well—at least in cases of contagious diseases; and this is the whole secret of your method of cure, if I am correct. Under ordinary conditions a colony will not kill off its sick when it becomes weakened down; but by mixing the races, as it were, family ties have no particular influence, and then it is that the sick are separated from the well, and Nature does the rest. Although, as I said, friend M.'s treatment gives us a gleam of hope, yet not until I shall find that it works with equal success in the hands of others as well shall I begin to believe that we have a real cure for bee-paralysis.—Ed.]

## BEEES AND GRAPES IN CALIFORNIA.

### DAMAGE DONE BY BEES INFINITESIMAL.

*By F. D. Love.*

On page 223 I see an article from G. F. Merriam, relative to bees and grapes in California—their harmony with each other, etc.; and, further, that you solicit such valuable testimony from that source where it has been said that bees were a great detriment to the fruit industry.

I will just say that I happen to be in that particular locality. The principal fruit grown there is the muscat grape, which is made into raisins. Also large fields of alfalfa abound here, and, of course, the honey-bee has claimed a home. Apiaries of 150 colonies, more or less, are located from  $\frac{1}{2}$  mile to  $1\frac{1}{2}$  miles apart. On my ranch of 60 acres I have 25 acres of muscat grapes, which I convert into raisins. In the center of this vineyard I have an apiary of 115 colonies in Jumbo hives.

About the 10th of September the grapes are highly sugared, and are then picked and evenly laid on trays of 25 lbs. each. Immediately

after these trays are delivered over to the heat of the glorious sun they are all visited by a merry gang of bees; but, watch them closely for a few minutes. Here and there they dart with vivid rapidity, for they seem to scent something that is sweet. In the picking of the fruit there will always be a few grapes that have lost the minute stem that holds it, and the delicious nectar has begun to ooze, and the bee has claimed it for its own. There are also some grapes that are bird-picked, and the bees proceed to finish them, leaving nothing but the hull, which the grader always blows over.

So far bees have done no damage to my raisins; but I do know that some people here have been so zealous they actually gave testimony that the bees were boring right through the skins, when, in fact, the puncture was always made by something else.

Among other fruits I have apricots, and as yet the bees have the first time to molest them in drying time.

The damage done to raisins by bees is so insignificant that it is hardly worth mentioning.

On page 320 you have illustrated a huge machine in the shape of a section-press and foundation-fastener combined. It has always occurred to me that the essential thing in modern inventions that counts best is speed. There is no question in my mind but that the Daisy fastener caps the climax over all; and the strangest part of all is that more prominent bee-keepers do not use it. As for his section-former, there is unquestionably too much material in its construction. I have a press, the invention of which is original with me—is the simplest device that has come to my notice. Regardless of its merits and demerits I desire you to know that I have attained a speed on it of 1000 per hour. Its work is first-class, and, like Mr. Aikin's machine, there is only one made, and it is not for sale.

Rosedale, Cal., May 24.

[If you do not object we should be glad to receive a photo or drawing of your press, together with a short description. With no desire to throw your feat in the shade, I would simply state that one of our girls folds, with the Hubbard press, 1000 sections in 40 minutes, and this is her average right along. She has folded 500 in just 15 minutes.

Thanks for testimony regarding bees and raisins. It is another clincher among scores of others of similar character.—Ed.]

## THE BEE-KEEPERS' UNIONS.

IS THERE NEED OF TWO SUCH ORGANIZATIONS?

*By Prof. A. J. Cook.*

*Dear Editor Gleanings:*—I like the thought and spirit of your editorial in which you urge that there ought and must be no feeling in the matter of the old and new Bee-keepers' Union.

I do not, however, agree with you that there is room for both organizations. We as bee-keepers are not numerous or rich enough to maintain the somewhat expensive machinery of the two organizations. One or the other, I believe, will soon cease to be. I think so, because I believe there is no excuse for both.

The first proposition, that there should be no ill will or bad blood, is too abounding in good sense to admit of argument. The day of animosities and invective among apiarists is long past. You remember, Mr. Senior Editor, when you and I first put hands to the apicultural plow, before the '70s, how much of rancor there was in our ranks. You remember the storms in the days of the Cleveland convention, when you and I first met. Happily that spirit and feeling are wholly gone. Surely happily for us, for I veritably believe that, if it had not gone, we would not have come. You, my friend, have done much to bring the better day; and God be praised for the success. No, we have no time or room or appetite for aspersions or ill will. A letter from Manager Newman, of the old Union, leads me to conclude that there is a serious misapprehension among the members of the old Union. I certainly did not understand the matter; and if not I, an officer, then probably not many of the others.

Mr. Newman says the old Union can not attack any evil but such as it has combatted in the past. Thus it can not fight adulteration. The last vote, he says, has settled that question. Now, I did not think our vote took any such effort from the hands of the Trustees or Executive Board. If so, I am not sure but, on the plea of "self-preservation," we should disregard such vote, for the old Union has got to fight living issues, or die. It can not live on its past record, excellent as that record is; nor can bee-keepers afford to support two unions. Such action is senseless, and bee-keepers have sense. I voted against amalgamation, not because I objected to it personally, but because I believed quite a number of the members did oppose it as unwise; and it seemed to me that, when men had joined an organization, and paid money into its treasury, we should not change that organization unless the vote was nearly or quite unanimous. I was assured that a goodly number did seriously question the wisdom of amalgamation. I did not suppose I was voting to tie the hands of the Union, or confine its labors to lines no longer important.

As suggested above, I fully believe that one or the other of the present organizations will die. The division is expensive, has no excuse, and the fruits of one strong vigorous organization will be abundantly greater than of two struggling feeble ones. It will be a case of "survival of the fittest." Emerson said of the individual, "Not to change is to die." I believe we can say the same as truly of the old Union.

Thus I wish to urge all the members of the old Union to write at once to Manager Newman, 2006 Market St., San Francisco, and urge that the Bee-keepers' Union at once grapple with the question of adulteration in California. If he replies that he can not do so, then ask that a vote be taken. We now have a splendid law in this State, and the people are alive to the iniquity of the business. A pure-food congress has just been held in San Francisco, and the people are fired with a sense of the enormity of the evil and the necessity of fighting it to the death. A vigorous blow struck now by the Union will do untold good, and will inspire people with the thought that it still has power, and is willing to show it by striking effective blows at any threatening evil.

Mr. Editor, I come to you, for I know you will heartily agree with this proposition. I hope you will urge its importance, and that action may be commenced at once that will incite the old Union to grapple with this monster evil. I have no feeling in this matter other than for the good of the cause. I take it no one has. I have already urged, in the strongest terms possible to me, in the *American Bee Journal*, that we take this matter in hand. May I not ask that you urge the Vice-presidents of the B. K. U. to write at once to Mr. Newman to commence action or else take a vote on the matter? We have a rare opportunity to achieve great good. We must not let it pass unimproved.

#### NOTES.

This bids fair to be an exceptionally good year, even for California. The large rainfall of last winter, and the genial warmth and sunshine, coupled with damp nights and absence of hot winds, almost insures a remarkable honey product in 1897. Already the crop has measured up well, and we are yet only at the dawn of the season. I never sampled finer honey than I have eaten this season—first from the orange bloom, and now from the sage.

The white sage is now in its prime, and the bees are jubilant as they fairly swarm upon the delicate flowers. The sage grows in long stems, and the bloom is in long racemes, which commence to blossom at the bottom, and open upward. Thus the plants are in bloom for long weeks. This is one reason why the amount of nectar produced is so great. I believe that this flower has few equals, and California climate is just the one to bring it to its perfection.

The above remark regarding the long-time bloom of the white sage is not alone peculiar to that plant, but is a characteristic of all of the California flora. Flowers that opened in February and March this year are still in bloom. Some of the most important honey-plants, like "California buckwheat," bloom for months. The blossoms are now out, and will be in December. I believe it is this duration of bloom

that will ever place California at the extreme front as a honey-producing State.

I have seen and tasted comb honey the past few weeks that certainly was the equal of any I ever saw anywhere. Yet comb honey will never be the chief California product. The distance to market, and liability to break down in transit, the danger from insects, and the greater labor of production, and less yield, all give preference to extracted. Extracted honey, then, will always take the lead here.

Last year I handled several tons of extracted honey. There were only two complaints made; one that some of the cans were old; the other, that the honey was often mixed. This is important. No man can afford to put honey in old gasoline-cans, no matter how well cleaned or how cheaply secured. Sage honey is water-white; buckwheat, beautiful amber. The latter will never sell for so much as the former; therefore it behooves every bee-keeper to keep a sharp watch and not mix the two kinds; for all that contains the amber honey, even though in small proportions, will be discounted in the market. Carelessness in this regard will be expensive. Clean new cans and thorough grading will pay a tremendous profit on the extra expense.

It is reported that San Diego County will ship fifty carloads of honey the present season. It is probable that the other counties of Southern California will do as well.

This is a good year for testing the value of the Bee-keepers' Exchange. It is certain that this is a move in the right direction. Before many years all our industrial pursuits will have exchanges. Why not all join now and speed the glad day? The gain in purchase of supplies and in sale of product must be considerable. It is hoped that nearly all in California will join the Exchange.

Claremont, Cal., May 31.

[You are not the only one, Prof. Cook, who did not understand how he was voting on the question of amalgamation that was submitted time ago. I had hoped that it would not be necessary for me to say any thing by way of criticising the policy that Mr. Newman has all along pursued; but I can hardly avoid doing so if I explain *why* I can not fully fall in with the plan you have suggested.

A few years ago, you, with the rest of us, voted to have the constitution of the Union changed so that it could take up the question of adulteration, or, in fact, any question that might be decided upon by its officers. When it carried unanimously we thought something would be done. But Mr. Newman has persistently kept the old Union working practically along the old line of defense; and I see no reason for thinking he would not continue to do so as long as he is General Manager. For this reason we do not feel like using the influence of GLEANINGS in trying to force upon him the necessity of taking up adulteration in California, when he is so manifestly unwilling; for one can not carry out a plan that he is not heartily in sympathy with.

I feel that we must look to the United States Bee-keepers' Union or to the California Bee-keepers' Exchange for help in the manner you have indicated in your article. The same effort in those organizations, along the line of fighting adulteration at least, would be productive of much more good. Personally I should be glad if the old Union would help along the good work already instituted in California; and I am authorized to state that A. I. Root, one of the directors, would be in favor of having the old Bee-keepers' Union take up the line of work suggested.

There is just as much room now for the two organizations in the United States as formerly. If the old Union shall insist upon continuing in its old work, its field will be narrow. The new Union is practically the old North American, with added functions of usefulness. There has been room for the two organizations in the past, and I do not see why there should not be room for them now. I feel confident with you, however, that, if the old Union does not make a change, it will die a natural death, and a new one will take up the work along lines that are commensurate with the needs of the times.

I am glad to note that you, Prof. Cook, are heartily in favor of the object of the new Union as set forth in the constitution of the new one; and therefore it seems to me your efforts should be directed in the channels of that organization. While it will not be able to accomplish much the first year, it has a backing of men in it who will make it do something in the future if others will take hold and help with their dollars.—Ed.]

#### PREVENTION OF AFTER-SWARMING.

*Question.*—Would not a queen-cell just about to hatch, or a virgin queen, introduced into a hive immediately after its colony has cast a prime swarm, prevent after-swarming by the young queen tearing down the cells before they were ready to hatch? In this way would there not be a great advantage by furnishing the colony a laying queen a week sooner than they would otherwise have a laying queen, besides stopping after-swarming?

*Answer.*—The above seems very simple and easy to answer at first sight; but upon a closer look it will be found to embrace some of the most perplexing questions which ever come up to the thoughtful, practical apiarist. Let us look at the matter somewhat closely and see what we can find in the text given us. It is assumed that, if a queen-cell or virgin queen is given to a parent colony immediately after it has cast a swarm, said queen, from the cell or otherwise, will go to tearing down the queen-cells left in the hive when the swarm issued therefrom. This is not the first time I have heard this assumption; but it is rarely that a greater mistake is made; for in nineteen cases out of twenty, if the swarm is hived on a new stand the cells will not be torn down, and not

once in five times where the old colony is removed to a new stand, the swarm being hived where the old colony stood—at least, this has been my experience in a practice of nearly 30 years. The bees do not want those cells torn down, for in them is cradled the choicest thing they have—that which they valued more than they did their own dear mother, and that which sent her out from her own home to seek a new one in some strange land; and if they considered them better than their own mother, are they now going to sacrifice them for any stranger, one on which they had bestowed no care or wish? By no means, only as they are forced to do so by being thrown out of a normal condition by having all of the field-bees drawn off by a removal of the hive from its old stand, or by the apiarist cutting off all of these queen-cells. And even in this latter case they will often kill the virgin queen given, or destroy the cell, preferring to rear a queen from their own sisters in the egg or larval form, which still remain in the hive, rather than to accept a stranger.

But, in passing, let me notice that expression, "the young queen tearing down the cells." We read it in this way more often than any other; but an experience of over a score of years (watching) along this line proves to me that, only where the queen has access to queen-cells without other bees, or in very weak nuclei, does she do the work of tearing open the cells, but the workers do it themselves. All know that, when the bees wish to protect these queen-cells, they can do it against the wishes of the most enraged queen; and when they change their mind they are just as ready to secure the destruction of the inmates of the cells as is the enraged queen; so all hands turn to, and the inmates of the cells are dragged forth and cast out of the hive, without even a single mourner. Whenever an introduced young virgin queen is accepted by the bees, of course the cells are all torn down and all after-swarming given up; but the rule is that it does not work that way, but the cell or queen is destroyed; and unless they conclude not to swarm when the first of the queen-cells left when the swarm issued hatches, after-swarming is the result, just the same as it would have been had we not given the queen or cell, and we find we have had all our labor of raising and giving the queen or cell for naught.

But, suppose we did succeed in this matter; would there be any gain aside from stopping after-swarming? Well, that depends altogether upon the locality, and the result in the end. With a continuous honey-flow from the time of swarming to the end of the season there would be considerable gain, provided the advantage were not lost by swarming again. With such a continued honey-flow the colony having such queen given to it would be far more likely to

conclude to swarm again than would the one where the bees had their own way, and they did not get a laying queen till near the time the brood had all matured which was in the hive when the old queen left. The conditions bringing about prime swarming are, plenty of brood in all stages, *plenty of bees of all ages*, and honey coming in from the fields. With any of these lacking, prime swarms rarely issue.

Now, where the honey-flow keeps right up, and the bees take their own course, or all after-swarming is prevented by the apiarist cutting all cells after the first young queen has hatched, the colony is without a laying queen for from eighteen to twenty days, as a rule, which makes a break in the usual hatching of bees for that length of time, so that, when the bees from the young queen begin to emerge from the cells, the hive does *not* contain *bees of all ages*, hence such a colony rarely ever swarms again that season unless more prolonged than we generally have it in the most part of the United States and Canada. But where a virgin queen is given, this break in bees is not very pronounced; hence colonies having such queens given them are quite likely to swarm with a prolonged honey-flow. Where the honey-flow is mainly from one or two sources, as it is with us, I think such giving of a queen a positive disadvantage, for the larvæ from her eggs are fed on honey which the bees are gathering from the field, which otherwise would go into the sections, that these larvæ, when hatched into bees, may become useless consumers of the honey of the hive, they having come on the stage of action after the honey-harvest from basswood is past, and before fall flowers think of giving any honey.

Where the colony has its own way, no honey is consumed by larvæ for 20 days, hence that much more is saved, and the break in bees comes just at a time when they are not missed, no honey-harvest being on, with enough bees remaining to care for all the brood the young queen produces, and this brood matures into bees in just the right time to take advantage of the honey-flow from fall flowers. A "weather eye" sufficiently skilled to secure a maximum of bees just in time for the honey-harvest, and as few at all other times as is consistent with this object, is something worth coveting by every practical apiarist.

---

*M. L. R., Pa.*—Where a colony is very strong, having, as you say, half a bushel of bees, and the hive is of good size so as to give them plenty of room, they are not nearly so liable to swarm as where the colony is smaller and their quarters are cramped. The circumstance you relate of this half-bushel of bees not having swarmed for six years is perhaps a little out of the ordinary, but by no means rare.

**APIS DORSATA; DR. MILLER'S POSITION EXPLAINED.**

Mr. David N. Ritchie writes that he is not satisfactorily answered on p. 189: that I do not object to the importation of *Apis dorsata*, and that those who do object give no satisfactory reasons for their objections. He thinks it need not be an expensive job for the government, and especially condemns any objection that it would bring down the price of honey, for we should be glad to have the poor supplied, and hopes government will be urged to import the big bee.

J. S. Scott takes a different view, and says:

"If it is good policy to increase the production of honey solely for the good of the public by making it cheaper, why does our government place a duty on foreign honey?"

No doubt if all the bee-keepers would unite in asking to have the tariff taken off from honey the request would be granted. Mr. Scott says:

"Is it not likely that, if the giant bee should prove a good honey-gatherer, and, like the bumble-bee, be of no use to us as to the production of honey for use, *Apis dorsata* might also divide the honey secreted by other flowers frequented by our own bees?"

If nothing I have heretofore said gives friend Ritchie the impression that I object to the importation of *Apis dorsata*, I will here say that I do object in the most emphatic manner to their importation till it is first known that they can be domesticated—not on selfish grounds, for I don't believe *Apis dorsata* would live in Northern Illinois; and if they should hurt the honey crops of the South, that might benefit me. But if they can not be domesticated, I see no manner of use they can be; and I can see that, whatever honey an undomesticated bee should gather, would be just so much less to go into hives.

As I have already said, if the government is to do any thing about it, let the appropriation be doubled, if necessary, and let domestication of *Apis dorsata* be thoroughly tried in its own country; and when that is satisfactorily settled it will be time enough to bring it here.

But it isn't best to get into any heated controversy about it, for The A. I. Root Co. seem to have taken in hand to solve the problem as to domestication; and if the attempt to domesticate should prove successful, no doubt their enterprise will land the bees here before the government could decide what to do about it. Now, mind, I don't know whether *Apis dorsata* would be a benefit or a damage; but I do know that I don't want it here till we know we can control it if we get it.

C. C. MILLER.

Marengo, Ill.

**THE KEEPING QUALITIES OF PURE HONEY; THE CALIFORNIA ANTI-HONEY-ADULTERATION LAW.**

What have you to say as to the keeping qualities of pure extracted honey? A late issue of the California *Fruit Grower* has the following gem in the body of an article commenting on our new anti-adulteration law. Addressing the article to dealers, grocers, shippers, and handlers of honey, it says: "They can not put up an extracted honey which in any way is a compound, even though it be a fact that an absolutely pure honey is lacking in keeping qualities. They can not manufacture or sell a honey which is an admixture, no matter how innocent or desirable that admixture may be."

From all information obtainable I judge the alleged lack of "keeping qualities" is going to be the plea of justification for adulterating honey. I wish you would take the matter up and bring out all the real information, both scientific and general, within reach. Let us be reformers.

C. H. CLAYTON.

Lang, Cal., May 1.

[That sort of argument in favor of adulteration, coming as it does from a representative of the middlemen, is mere bosh. It looks a little specious on the surface; but the fact of the matter is, there is nothing in the world, in the way of sweets, that will keep better than honey. A few years ago middlemen tried to tell us that it was necessary to put in a little glucose, at least, to prevent granulation; but after having carefully tested numerous samples with varying amounts of glucose, I know there is no truth in it. The stuff has got to be nearly all glucose before granulation is held in check. California has a good food law, and I hope it will stay on the statute-books in spite of the soft-soap nonsense of the glucose sympathizers.—Ed.]

**THE PETTIT SYSTEM OF PRODUCING COMB HONEY; A CORRECTION; IMPORTANCE OF STRONG COLONIES.**

Will you kindly allow me to trouble you and your readers with a few more words about my way of taking comb honey? I notice on p. 288, in Mr. Geo. G. Scott's very kind letter, a mistake that has crept in somehow. Mr. S. says, "The divider admits of two bee-spaces and the clustering of the bees therein, while the  $\frac{3}{4}$ -inch holes allow of easy access to either side." That  $\frac{3}{4}$  inch should be  $\frac{1}{8}$  inch. I beg to say that the system, for best results, must be used as a whole. Both the wedges and the dividers are indispensable for best results.

Another point: The bees must be strong. There must be bees enough to take possession of the whole super, or nothing will be gained—may as well go on in the old way. Now, if this statement is against the system, then so much the worse for it. I want to tell all I know concerning it.

The perforated zinc, as suggested by Mr. Scott, works well; but it is pretty hard to keep it straight. Only for that difficulty, and the

fact that it is not quite as warm as basswood, I should have advised the use of it for dividers.

S. T. PETTIT.

Belmont, Ont., Can., May 18, 1897.

#### AN IMPROVEMENT ON DUNN'S WHEELBARROW.

Tell M. H. Dunn that I think he can materially improve his wheelbarrow, illustrated May 1st, by cutting his cover in two, not having it hinged to his box. Use wire hinges where he saws it in two, so the lids (two half-lids) will fold over on to each other, out of the road. I make mine with a very light frame covered with drill, letting the rim of the frame project down on the outside of the box all around to exclude bees more effectually. The frame is stiffened by fastening triangular pieces of tin on the corners. His suggestion, to place the combs lengthwise in the box, is an improvement.

R. W. WILKIN.

Newhall, Cal.

#### NO PAPER IN FOUNDATION PACKAGES.

In "Stray straws" of May 15, as to paper between foundation, Dr. Miller asks, "What's it papered for, any way?" Well, I say for no use, for I made up 100 sheets one year ago, and they lay in a pile until a few days ago, and they were just as I left them, and separated as easily as the day I made them; and, still more, I had about the same number of sheets dipped and trimmed ready to put through the mill. They were laid up then, and a few days ago I examined them and found them as I had left them nearly a year before. I put them through the foundation-mill, and they were easily parted, and made fine foundation. No use for paper here in this hot climate. If I were ordering foundation I certainly would have the paper left out.

In Straws for May 1st it was said that, if the frames in the supers were crosswise of the brood chamber, the queen would not go alone. I shall try that soon as my hives are all square and will sit either way.

Prospects for much honey very poor here.

JOHN CRAYCRAFT.

Astor Park, Fla., May 25.

#### IN FAVOR OF USING PAPER IN FOUNDATION.

In regard to paper between sheets of foundation, page 362, I would say that from my experience with foundation in this climate, owing to the heat, and long distance it has to be shipped, much of it would get matted together, and be unfit for use, and have to be rendered into wax again, and sold at a loss to bee-keepers.

J. B. GRIFFIN.

Cat Creek, Ga.

#### HOW TO GET STOCK TO EAT SWEET CLOVER; BY A 12-YEAR-OLD READER.

Our bees came through the winter and spring all right. First swarm, May 18. We have a

better prospect this spring for honey than we have had for many years. They are storing surplus from locust. We moved into this valley this spring, and found that there were but few bees here, and what few there are have very little attention. You can easily guess the result.

There is sweet clover along the road for four or five miles. No one seems to know how it got there, but I suppose some bee-keeper knows. Papa kept his stock on dry feed till they were nearly starved for something green. He thought they would eat any thing. When they were turned out on sweet clover they smelled of it and gave a snort and ran away for something else. So mamma cut some in a box and put some salt and bran over it, and they ate it all up, and have eaten it ever since.

Bernadotte, Ill.

NORA NEFF.

Big prospect for honey; it is coming in like an avalanche, working me a little above the upper notch.

M. L. WILLIAMS.

Maysville, Ky., June 8.

We are having a regular old-fashioned honey season. Bees are "just rolling in" the honey.

Morgan, Ky., June 8.

J. P. MOORE.

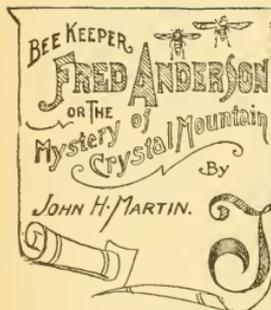

M. D., Tex.—We can give you no information in regard to producing honey wine, or, as some call it, honey mead. We have never given any thought to this use of honey, as we believe there are other and better uses for it, both from a moral and financial standpoint.

C. H. G., N. Y.—There is no method that we know of for bleaching comb honey after it has once been taken from the hive. Comb honey in the first place should not be left in the hive any longer than is necessary to have the capping completed. This will prevent travel-stains.

W. W. Y., Ky.—Sometimes swarms in the air are very cross, and no definite reason can be given why they are so, unless they are vicious hybrids in the first place. Pure blacks or pure Italians, when they swarm, are usually quiet unless they are molested or jarred unnecessarily in taking the cluster off the limb.

R. T., Ky.—Transferring should usually be done before the honey season. We recommend fruit-bloom; but shortly after will do nearly as well, providing you do not get the bees to robbing. For particulars on how to transfer, see page 32 of catalog, also "Transferring," in our A B C book.

HE passage through this portion of the mountains was merely an enlarged cleft; and immense layers of obsidian, like great sheets of black glass, rested against and were part of the mountain above. The tremors of the earthquake had dislodged one of these layers, and, sliding down, it had completely covered the passage. The heaving mass of mud and lava was now rising slowly but surely. All semblance of the beautiful valley had disappeared, and again the place was returning to its primeval condition—a turbulent volcanic crater.

The squaws, in weird tones, repeated their death-chant, Alfaretta kneeling near them, her beautiful face turned upward in silent prayer.

The rest of the party for a few moments were mute with their various emotions. Fred seemed to forget self, and to divide his attention between Alfaretta and the rising tide of destruction. Walking quickly to the sheet of obsidian that had cut off their means of exit he found that it was only two inches in thickness; then hastening along the terrace he luckily found a heavy iron bar that had served as a part of the elevator. With this he approached the obstruction on the run, and under his rapid blows it soon gave way and finally came down with a crash. Sam and Gimp were on hand with a shout, to help clear away the debris. There was hope again lighting up every face, as the exit was cleared. The doctor bade Alamantapola take the lead into the passage. Alfaretta followed, and, forcing every one hurriedly along, he brought up the rear. For a moment he looked back over the strange scene of desolation, and seemed loath to stir until Fred, retracing the few steps he had taken, urged the doctor to hasten.

"I can not help looking back," said he, sadly; "and my memory always will look back longingly to what was once my beautiful valley. Our loved ones, our homes, our things of beauty, our attachments to earth, must all be taken from us."

"But, doctor," said Fred, "we can not think of these things now. We must hasten. See! the boiling mass is near our feet now, and there may be other obstructions in the passage."

"True, true," said the doctor, sadly, and hastened with Fred into the passage.

There was, fortunately, no further obstruction, and at the outer exit even the great rock door was toppled from its balance, never more to respond to the bidding of its master. The doctor again stopped and looked regretfully at the massive stone.

"The broken key, the ruined safe, robbed of quietness and pleasure, what is there now to live for?" said the doctor.

Another tremor of the mountain, and a hot puff of sulphur smoke came from the passage they had left, and they all made greater haste down the canyon; and while the doctor was brooding over the catastrophe to his valley Fred felt a new sense of freedom as he sped along, helping and half supporting Alfaretta in her flight. When fully two miles away they felt it safe to rest, and sat or reclined upon the brown earth as fancy or their condition of fatigue dictated.

Alfaretta here, after regaining her composure, said, with much feeling, "Fred Anderson, how grateful we should all feel toward you! But for your timely action I really believe every one of us would have been swallowed in that terrible pit."

"Let us say it was providential," modestly replied Fred. "As I think of my action it seems to me I was but an instrument to accomplish a desired end."

"Aye," said Dr. Hayden, "'Behind the dim unknown standeth God within the shadow, keeping watch above his own.'"

Again they were admonished to proceed, by other tremors of the mountain; and after a long and tiresome walk they arrived at the Indian rancheria. To the doctor's astonishment the Indians had been so exercised by the earthquake that they fled to the valleys further west, and near the coast.

It was near evening, and the party made themselves as comfortable as the circumstances would permit. Each person had brought a blanket, and, with a roaring fire in the large round house of the rancheria, each one felt safe for the night. Alamantapola and her companion found food enough cooked near the rancheria; and, though the food consisted of dried grasshoppers, these, when cooked properly with a little flour, made an appetizing meal.

During the night there were continued tremors of the earth, and sleep was not enjoyed in that camp that night, and all faces wore traces of anxiety.

Early the next morning preparations were made for a long weary walk to Covelo. The two Indian women would not leave their rancheria. When urged by Alfaretta to go with her, Alamantapola replied, "Um Indian return by'm-by. Me no 'fraid. White squaw go to her people. Me stay with my people, um good-by." Then the two women squatted stoically on the ground, as was their custom, and they crooned a song of farewell.

"It shall be," said the doctor; "and while we wait here, Fred may ride back to the rancheria, where perhaps he can find a saddle."

As Fred disappeared, Alfaretta, addressing the doctor, said, "But, doctor, do you own the pony?"

"No, my dear, I do not; but is it possible, Alfaretta, that you never remember riding that pony?"

"I certainly do not, doctor."

"That," said the doctor, "is your own pony, and the one Fred has told you about so many times."

"Oh dear, dear!" said Alfaretta, leaning her

"TAKE THAT, YOU LOW-LIVED MISCREANT!"

The little party, now reduced in numbers, had proceeded but a mile when they saw a couple of riderless ponies coming in the distance. When they approached, one of them proved to be Alfaretta's pony Jack.

"Up to his old tricks," said Fred; "has taken French leave of the Indians, and made for home, and how opportune!"

Fred and the doctor looked anxiously toward Alfaretta, and she, her face lighting up with a smile, said, "What a pretty pony! I do wish it were mine."

head upon her hands; "this is all so strange. I wonder if I shall know my own people."

For half an hour they conversed about her past insanity, and the great change that had been wrought for her in the beautiful valley; and while she was now sane, the valley itself had gone crazy.

Fred soon returned, having found the saddle; and with the two ponies Alfaretta and the doctor were provided with easier transportation.

When the little party entered Covelo, Alfaretta was recognized as the lost young lady.

The man Slim Jim would never forget the girl who gave him the lashing with her riding-whip. Dr. Hayden was also recognized as the mysterious man of the mountain. The people were not so terror-stricken by the earthquake but they could give attention and create quite a commotion around the doctor and his companions. Pete Armstrong, who had hunted the doctor with guns, and had once shot at him, was anxiously looked for by the crowd.

Slim Jim evidently had no good feeling toward the party, and, remembering the episode in which Alfaretta had struck him over the head with her whip, his questions and his conduct toward her were so covertly insulting that Fred, though indignant, kept his temper, and in a gentle tone of voice reminded Jim that it was the part of a gentleman to treat a lady with respect.

This excellent advice increased his ire, and he now turned a good share of his abuse upon Fred. The latter was pleased that he had drawn at least a portion of the abuse from Alfaretta. The continued abuse, however, so wrought upon Fred's sensitive nature that at length, forgetting to curb his spirit as he should, and forgetting that he endangered the welfare of the rest of the party, like a knight defending a fair maiden he slapped Slim Jim on the mouth.

"Take that, you low-lived miscreant, and that," as he followed it with another.

The crowd fell back, shouting, "A fight! a fight!" "Make a ring!" "Come, Jim, will you take that?"

"No, I won't take it," said Jim, livid with rage. "But I'm no fist fighter. I want deadly weapons. I say I want deadly weapons. Now, young man, if you have any sand in yer dandy body, jest walk right out with yer deadly weapons; and the quicker ye decide, the better."

At this juncture Pete Armstrong rode up, and, dismounting, made his way into the crowd. It was not necessary for him to ask about the excitement, for several voices shouted, "The mystery man of the mountains."

Pete Armstrong was a noble type of the young American, and Fred and the doctor felt instinctively that they would have fair treatment at his hands, while the crowd was so vicious and unreasonable as to refuse to listen

to the explanations the various members of the party had essayed to present.

Young Armstrong gathered the party under the saloon-awning, and said:

"Gentlemen, I believe in the great American idea of fair play; and while I would have shot this mystery man had I met him in the mountains, it is no more than fair that, as he is in town, and has in his party the young lady and boy alive and well, whom we thought dead, I propose to listen to each person's story; and if their explanations are founded on reason, I am willing to let those who are innocent go their way, and the guilty receive the punishment due them."

"But, Pete," said Slim Jim, "this young dandy slapped me in the face, and I have enalleged him to meet me with deadly weapons, and I don't want to be interrupted in this thing by your personal matters."

"Ha, ha! personal matters!" said Pete. "Well, then, young man, what do you say? Are you willing to meet this aggrieved man with deadly weapons?"

"I certainly am," said Fred. "And as I am the challenged party I have the right to choose the weapons. We can settle this matter in a few minutes."

"All right, boys," said Pete. "We'll let the fun go on, and attend to serious matters afterward."

Seconds were duly chosen, and, though the doctor mildly persuaded, and Alfaretta urged, even with tears, to prevent the disgraceful scene, Fred was determined; and, though a very conscientious and moral young man, he seemed just happy at the prospective danger before him. Pete Armstrong, seeing that both were determined, told Fred to choose his deadly weapon, time, and place.

"Well, then," said Fred, "I propose that a circle eight feet in diameter be marked off upon the ground. Each party to the duel shall take his stand inside said circle, bareheaded, and his body stripped to the waist. Each party shall be provided with a peck basket, with a cloth cover. Inside said basket must be at least two quarts of live honey-bees. Each party, while keeping within the eight-foot circle, shall throw honey-bees into the hair and upon the naked body of his opponent, until one or both are stung to death. or until one cries 'Hold, enough!'"

---

A SHORT time ago a question was asked in the Question-box department of the *American Bee Journal*, whether it was advisable to use deep-cell-wall foundation in sections. A few answered no. It is very evident that some had never seen it, or at least had the impression that the new foundation was clumsy, and not the beautiful delicate article it is. Mr. Mc-

Evoy, one of the respondents, not having seen the new foundation, answered in the negative; but later on he saw a sample, and frankly acknowledged to Mr. Holtermann that, if he had seen it at the time he made the answer, he would have replied in the affirmative. This, I judge, would have been the case with the others who answered no.

The next convention of the United States Bee-keepers' Union will be held on Tuesday, Wednesday, and Thursday, Aug. 24, 25, 26, 1897, in Buffalo. These dates occur during the regular meeting of the G. A. R., and of course railroad rates will be low.

After the foregoing was in type the following from Dr. Mason came to hand:

Railroad rates have been secured by the G. A. R., of two cents a mile for the round trip, that is, one cent a mile each way, in all territory east of the Mississippi river, including Canada; and in all territory west of the Mississippi the rate will be one fare for the round trip, tickets to be good going on the 21st to 24th inclusive, in all territory. Tickets must be bought for the G. A. R. encampment, and not for the U. S. B. K. U., and will be good for thirty days if vised at Buffalo, information in regard to which will be given to those attending the convention. Information in regard to hall and hotel rates will be given as soon as obtained.

To those living west of the Mississippi, I would suggest, although it may not be necessary, that it may be cheaper to buy tickets to the east side of the river at the regular rate. A. B. MASON, Sec.

#### PROSPECTS FOR HONEY-FLOW.

In our locality at least, basswoods will yield no honey, for the reason that not a single blossom can be found upon any of the trees in the streets of Medina, nor on those in the forest. Examination of the buds at our basswood orchard shows a like condition. I do not know how far this condition may prevail throughout the country.

The heavy rains in the early part of the season have given clover a great stimulus, and reports everywhere show that it is growing profusely. If these cool nights will only give way to warm ones, we shall expect at least a good flow of honey from clover. Taking it all in all, the late spring and early summer have been decidedly cooler than for several years. It is generally supposed that warm nights and hot days are favorable to a honey-flow; but judging by the way the orders are pouring in from every quarter of the country, making it necessary for us to run day and night, it would look as if honey were coming in, even if the conditions were not exactly favorable so far as temperature is concerned.

#### A MILLION-DOLLAR COMMISSION FIRM.

It is not often that I mention editorially the name of a new commission house; but lately we have received application for space in our Honey Column, from Francis H. Leggett & Co., Franklin and Varick Sts., New York. Referring to the commercial agencies, Dun and Bradstreet, we find that their rating is of the very highest that either could give. We are very careful whom we admit into this column, and accordingly wrote to the firm in question, saying that it was our custom to allow space

in our Honey Column to reputable and responsible commission firms, free of charge, on condition that they neither handle adulterated goods in the way of honey, nor encourage the sale of it if they know it. In reply I received the following letter, which I take pleasure in submitting to our readers:

*Editor Gleanings:*—In reply to yours of the 1st inst. we would say that, in regard to handling adulterated honey, that is not our intention, and we certainly will work with you on this line. Any information in regard to producers, etc., will be cheerfully received.

Trusting that our relations will be of a pleasant nature, and hoping to see our ad. in your next issue, we remain

Very respectfully,

FRANCIS H. LEGGETT & CO.

New York, N. Y., June 3, 1897.

This firm, with its capital of a million and over, we feel sure, will be a great acquisition to our Honey Column; and although we have received numerous applications for space in this department, many of which have been rejected on various grounds, we take pleasure in giving these people space, even though they are strangers; and if they do not give their customers satisfaction we shall drop them out.

#### HONEY ADULTERATION; CANE SYRUP AND GLUCOSE.

WHEN an analysis of honey shows only 10 per cent of cane sugar as an adulterant, and no glucose, it does not necessarily signify adulteration. I believe the United States chemist stated, some time ago, that very small percentages of cane sugar found in honey could not be taken as positive evidence of fraud. If I am correct, nectar, just as it comes from the flowers, is chemically, to a great extent, a cane sugar; but after it has passed through the ripening process it is converted into what we call honey. Sometimes, when the honey is gathered and stored rapidly, it is not as thoroughly ripened at some times as at others. The consequence is, analysis shows a trace of cane sugar.

Perhaps our readers may think that, even if this is true, it would not be wise to give publicity to it, for the reason that dishonest persons would think they could add at least 10 per cent of cane sugar to their honey, and not be detected. No fear need be apprehended along this line, for the reason that good qualities of honey are sold so near the price of cane syrup it would not pay to put in so small an amount. But then it may be argued that it might pay to put at least 10 per cent in *dark* honey; but here, again, the price is as low as or lower than the syrup. If adulteration were practiced at all it would be syrup adulterated with honey, rather than honey adulterated with syrup.

But you may ask what specially called forth this editorial. A short time ago an innocent party was accused of adulterating, because the chemist found 10 per cent of cane sugar in his honey. I wrote to the party in question, giving the position of the United States chemist, and added that it was my opinion his honey wasn't

adulterated; that, if he were bad enough to go into any such fraud, he would not stop at 10 per cent, but would put in enough to pay him for doing it, and that would be 50 or at least 33 per cent.

On the other hand, when analysis shows a very small percentage of glucose, it is pretty certain that some one put it there. Glucose is very easily detected by the chemist, and it is no difficult matter to determine even the very exact per cent of it. The adulterant (glucose) by reason of its very low price, and the fact that it is almost devoid of any color, is what we have to fear. It pays, from a financial standpoint, to mix honey and glucose, provided the mixture can be palmed off as pure honey. But our food commissioners in our various States are becoming more and more alert; and with good laws back of them in every State in the Union, the chemists would enable them to hunt down the gully parties and make them pay the penalty of the law. The United States Bee-keepers' Union will undoubtedly work to secure the enactment of pure-food laws in States where they have none. There is no question but this is the proper way to handle the glucose problem.

#### HIVING SWARMS AT THE HOME OF THE HONEY-BEES.

SWARMS are beginning to come forth, and it sometimes happens that several of us have to take a hand in hiving them. The bees seem to take special delight in coming forth exactly at the noon hour, when we would like to have a little quiet, for we are, and have been for some time, running night and day.

On Friday, June 4, as I was standing in front of the basswoods near my house, talking with A. I. R., some one called out, "Swarm of bees!" They were just emerging from between the tall evergreens surrounding the apiary; and the way they were piling through led me to believe they meant to "light out" for parts unknown. I grabbed up a pail of water and a spray-pump, and started after them. As I sprayed, the little fugitives did not drive back like a flock of sheep, as they ought to, or as I have made other swarms do on many former occasions. They seemed to be driving right through my artificial storm. I followed them, nevertheless, slopping the water on myself, but keeping up a continual spray among the thickest\* part of the swarm. Mr. Weed, the foundation man, seeing my predicament, rushed to my assistance; and A. I. R. called on two of the gardeners to bring me buckets of water as fast as I used them up. Still the bees kept moving northward over the berry-patches, and over the raspberry-bushes, seeming to take special delight in gliding over objects that were serious obstructions to us poor mortals

\* Here I made the mistake. I should have sprayed the bees in the lead.

who had to climb through the bushes. Pailful after pailful of water was used up, and the bees were nearing the railroad track, and immediately over a pile of tile. I then got clear around on the outskirts of the bees, and wet down thoroughly the outposts, as it were, and finally succeeded in holding them at bay. As I was getting tired with the continual squirting, Mr. Weed took up the pump and went at it like a regular steam-engine. He set such a hot pace for himself that he was soon "outwinded," to use a little bicycle parlance. But he managed to hold them where I stopped them.

The bees hitherto seemed fairly wild to get away, and it looked at one time as if they would accomplish their object. Spectators here and there were eagerly watching to see which side would come out ahead, while the spray-pump was forcing water out among the bees. After getting them pretty well wet down they alighted on the tile, in the grass, in the road, all over every thing, and finally, to our delight, they began to form a cluster on one of the raspberry-bushes. Mr. Weed and I, in our eager haste, had sprayed almost as much water on each other as on the bees; for as soon as we drove back one set of outposts, another set would start in another direction "to make a break," and immediately the spray was turned in that direction, and it did not make any difference whether any one was in the way or not—he had to take his dousing with the bees.

To-day, June 10, another swarm came forth, and was starting off in a like manner; but this time I managed to get the spray on the very outskirts of the flying bees. I got them started back in the opposite direction, and with very little trouble forced them to cluster on the evergreens, and then of course we had things our own way.

I know of nothing that will ordinarily change the course of a flying swarm of bees so effectually as a spray-pump. As I have often described in these columns, I have generally been able to drive swarms like a flock of sheep in almost any direction I chose. I remember once a swarm was making off. I ran ahead of it, sprayed the leaders, changed the direction of their flight, and then chased them toward a certain tree; and, having arrived there, I held them until they chose to alight.

I never had a case before, I believe, where we came so near losing a swarm in spite of the spray-pump as the one I described at the outset, for it is very rare that we are not able to make them cluster very quickly.

We keep a pail of water, a spray-pump, a Manum swarmer, and a long pole, in the center of the apiary. As soon as a swarm comes out, we make for these implements of swarming; and if the bees act as if they were going to run away and leave us, then we douse them until they are glad to alight.

We should have to be more than human if we could so banish self and selfishness from our hearts that all our petitions would be asked in his name—that is, if our requests were to be consistent as coming from one who loves righteousness *more* than self. When we can do this, then God can safely answer our prayers. I was working and praying over that well with the thought in mind that the soft water would be a benefit to our town and to humanity; but I think that really my own selfish plans were mostly at the bottom of it. When we struck that vein of gas, so far as I can remember, my plans for utilizing it were all selfish ones—that is, the very plans I was so busy going over, and perhaps to some extent on God's holy day, and in his place of worship. It does seem a little singular that things I loved us in such unexpected ways in getting it started; but we can not expect to fathom God's plans and purposes; and perhaps this very Home Paper may do as much good as I have given it, honestly and truthfully, as any I have ever written. My experience, in fact, just now calls to mind that of a devoted Christian, an old friend of mine, several years ago. He was greatly given to new projects—to starting out in some new kind of business. Soon after the war, when rents were high, and people could buy lots and build houses on them, and sell out at a large profit, he got a scheme into his head of buying lots and making nice little homes for laboring people. He was sure he could plan something attractive and convenient, and something that would sell. In fact, he could think of nothing else, and prayed again and again that God in his providence would induce some good friend to place the means at his disposal. Just about this time a relative told him he had several thousand dollars lying idle, and that he could have it at a low rate of interest—perhaps at no interest at all—I can not quite remember now. This friend saw in it at once a wonderful answer to prayer. He took the money, thanked God for it again and again, and built his houses; but, unfortunately, there was a reverse, and a great decline in real estate and rents; and the outcome of it all was, that, in borrowing this money, he got himself into the worst trouble of his life. He came near losing his faith in God and in prayer. When he stated the case to me I told him at once where, as I thought, he had been making a mistake. Our prayers should all be prefaced and closed with the words of our dear Lord and Savior—"Nevertheless, not my will, but thine, be done."

I have sometimes thought that perhaps God answers our prayers in order that, by so doing, he may teach us wholesome lessons. Many of you have doubtless heard of the woman who prayed that her boy's life might be spared when he was very sick. She finally asked God to spare him under *any* condition—even to take her life if need be, but to spare the boy. He lived, and she lived to see him die on the gallows. This may be true or it may not be true; but I think it points a wholesome moral to us all. The human will should never be set up against God's; and if our faith is of a kind that causes us to doubt God because he does not give us just what we ask for, or because we can not exactly understand his reasons, then it is a very poor kind of faith indeed. Let us hold on as Job did; and let us also hold fast to our faith as did the patriarch of Uz when he said, as he rose sublimely above the narrow range of all things pertaining to this world, "Though he slay me, yet will I trust in him."

Still at thy mercy-seat, seat, Savior, I fall;

Trusting thy promise sweet, heard is my call;

Faith wings my prayer to thee; this all my song shall be, ♪

Jesus has died for me, Jesus my all.

THE STRAWBERRY INDUSTRY AT BARNESVILLE, OHIO.

For several years I have been thinking I should like to visit Barnesville, and see how they manage where they grow strawberries by the carload and trainload, and also see what varieties, where they plant whole farms to strawberries. Well, last Saturday evening I received the card below:

*Dear Friend Root:*—The strawberries are ripening now, rather late. I think the first of next week would be a good time to visit the patches. I shall be pleased to show thee around. WM. L. ASHTON.  
Barnesville, O., June 4.

With the rush of business now upon us, it was hard for me to be away for even one day, and I could not afford to waste any time by waiting for trains. So I looked up the state of things on the new wheel-book sent out by the L. A. W., and found that our Medina railway strikes a station in Belmont Co. called Bannock, where a limestone pike goes down to the old national pike; and by making a wheelride of toward 20 miles over these stone pikes I found I could reach Barnesville without any waiting. I will not stop to tell you about my wheelride, but only say that I met with about the usual number of adventures. In fact, I am bearing the scars of some of them while I write.

I was warmly welcomed by our Quaker friend and his boys, for he proved to be the superintendent of the Quaker school, a mile out from Barnesville. Near by was one of the strawberry-fields; and my first introduction to the strawberry-grower brought back a host of memories belonging to forty years ago or more. Shall I tell you why? Well, it was because the introduction was something like this:

"Brother Smith, this is Amos Root. Brother Root, I make thee acquainted with Solomon Smith."

"Amos Root!" Away back in my boyhood, when I was so bashful that I wanted to slip around out of sight rather than meet strangers, they used to call me "Amos Root;" and somehow or other it did my heart good to be called by that old familiar name. It seemed to say to me, "You are at home, and among friends—yes, friends indeed;" and it seemed to strip off business and business cares. Just the very words made me feel that I was a boy again—a quiet, backward, awkward boy; and it made me feel, for just a little time, loose from all business entanglements and complications. I do not know but I drew a long breath of relief. "A. I. Root" does not sound boyish; neither does "The A. I. Root Co." And, oh I do so love to be a boy once more when I get away off with my wheel!

My first glimpse was of a patch of berries on a southern slope; and, by the way, there are slopes and nothing but "slopes" around Barnesville—every thing slopes—garden-patches, whole farms; but, notwithstanding, I believe Belmont Co. is the most thrifty and the finest-looking agricultural county I ever saw anywhere in all my travels. Every bit of ground is covered with something green at this time of the year. No matter how steep the hillsides, nor how high their summits, something is growing. The forests have been mostly cleared away, and cultivated fields—that is, fields over the hilltops and down in the valleys—take their places.

The strawberries are grown in matted rows, just about according to Terry's directions. The ground was well mulched with straw in the fall, and there has been no cultivation since, except to pull the weeds; and just now they do not even do that very much, because the weed brings up a lot of dirt, and that is pretty sure to make the berries gritty.

The first row I struck was our old friend Warfield, that I have just been talking about; but the Warfield berries were larger than we have ever grown them here in Medina Co. This is owing to having the plants not too thick in the rows, to the rich gravelly loam on the hills, and to the great amount of stable manure or other fertilizer used. Almost every grower I visited, however, threatens to stop putting stable manure on strawberries, on account of the weed seeds. Some are using phosphates; but the greater number, I think, are using bone dust and ashes, or some other preparation of potash, in place of stable manure.

□ I felt anxious to know how many of the varieties we have been advising and recommending were flourishing there; and my good friend Ashton smiled when Bro. Smith told us that one of their best berries was the Warfield. Now, they have around Barnesville the very berries we have settled down on, and but only a few other kinds. The Jessie has been partially dropped, although a few growers still stick to it; and the same with the Parker Earle. Michel's Early they grow for extra early, but for no other reason. Bubach takes the lead for a large strawberry. Where Bubachs are grown with the plants far enough apart, so as to have plenty of room, they select choice specimens for fancy city trade. Such berries bring from 25 to 40 cts. a quart. Where you can get, say, ten berries that will fill a quart basket, it is not much trouble to find a purchaser for them, among traveling people on the railways, at from 30 to 40 cts.

Since my visit I think more of the Bubach than ever before. The Edgar Queen, I believe, is not grown around Barnesville, and it is the only one we catalog that has not found a place there. Brandywine is just beginning to attract considerable attention. It does not bear as many berries as the Bubach, perhaps, but they are so firm they can be handled and shipped almost like potatoes, even when they are well colored all over. This is certainly a wonderful thing in its favor. The Marshall has been grown to some extent, but I believe it does not produce berries enough for field culture, as a general thing.

One of the largest berry-farms in the neighborhood of Barnesville is managed by the Cowan brothers, one of them having over 100 acres devoted to small fruits, and, if I am correct, something like 40 acres entirely in strawberries. We were a little surprised to find the proprietor a colored man; and it was a surprise indeed to see how he was making berries grow on every foot of the land, hilltop and valley. Even in the ravine back of his house, where it was about as steep as the roof of a house, great rank luxuriant strawberries were growing and bearing there. Mr. Cowan says the *side* of the hill is much better for strawberries than the extreme *top*. He thinks this is much owing to the cold winds that strike the summit, while the berries part way down, especially where the hill slopes to the southeast, are protected from the cold northwest winds. It was indeed amusing to see the great clusters hanging over and spread out on the straw mulching on the down-hill side of each row. The Haverland, you know, is remarkable for its long stems, and these were literally piled up in heaps. The

day before our visit, they had picked and shipped 50 bushels.

Mr. Cowan objects, like the rest, to stable manure for a mulch, especially that which comes from the livery-stables in town. I do not know just why manure from livery-stables should contain so many weed seeds, but perhaps it is because they have to purchase large quantities of hay from all sorts of farmers. A man who has a horse and cow of his own, or who grows the feed for his stock, would not be so likely to risk taking weeds on to his premises. Several men told me they had got their ground filled with kinds of weeds they had never seen on their premises until they brought them in by purchasing stable manure for their berries. Now, this is indeed a serious matter. Another source of weed seeds is the straw mulching put under the berries to keep them clean. The small quantity of grain left in the straw makes trouble, but the trouble is not as bad as with pernicious weeds. The prickly lettuce is one of the worst, because it will mature seed, and send it flying about even while the berries are fruiting.

Permit me to mention here that Mr. Cowan was using very successfully over a part of one of his fields the refuse from a cane-mill near by. It answers the purpose perfectly, contains no weed seeds whatever, and he said the only objection in his case was the distance they were obliged to go for it. In their work they use two tons of straw per acre, or its equivalent in something else. This, of course, is for mulching, to protect the plants from heaving out in the winter, and to keep the berries out of the dirt in fruiting-time.

The berries grown on this piece of 40 acres are mostly those I have mentioned. Warfield, Haverland, and Bubach are sure to be found; then Parker Earle, Jessie, and Michel's Early are grown more or less.

I asked Mr. Cowan how often he shipped berries that sold so low as to pay for only the packages, express charges, and cost of picking. He said he had never come out quite as badly as that, even on a single bushel, although he had heard of others who had to advance money, besides the value of the berries, to pay the expense of shipping and marketing. I was somewhat surprised at this; but when I became better acquainted with the man I found that he was unusually bright and wideawake. He is a hard worker himself, and he keeps right along with his help, which, if am correct, is mostly colored people.

□ There is a factory at Barnesville for making crates and boxes for berry-growers; and they have certainly got the prices down very low. The cheap gift crates to hold one bushel, or 32 one-quart boxes, are furnished at Barnesville, nailed up, for only 12½ cts.; and as the nailed-up quart boxes are sold for \$3.50 per 1000, the whole expense of a package for a bushel of berries is only about 23 cts.

The raspberries and blackberries were wonderfully luxuriant over those gravelly hills. It reminded me of my visit to Prof. Grannis, a year or two ago. When I asked how they got along with this matter of wash and gullying on the hillsides when under cultivation, friend Cowan explained that they made their rows of berries around the hill, something on the plan described at the last end of our tomato-book; then when the water gets through, and commences to cut a gully, they stop it by tramping in the trimmings of the berry-bushes. These are tramped down in place, and then held there by refuse stones until the ground settles around them so that vegetation gets sufficient hold.

Our colored friend keeps up with the times,

subscribes to the periodicals devoted to growing small fruits, and is a live man in every sense of the word. As we prepared to take our leave he informed me that, when he started in the berry business some years ago, he had only about \$200 or \$300 to make a payment on the farm. The place was already pretty heavily mortgaged. It was only a short time ago that the last dollar of the mortgage was paid; and now he can breathe a little easier while he plans to make every yard of ground produce fruit of some kind. Besides the strawberries he has considerable ground devoted to currants and gooseberries, and these have always paid him well. Instead of paying large sums of money to nurserymen for plants, he grows his own, makes cuttings from the currants and gooseberries, and has a very pretty little nursery where they are cultivated and cared for until they are ready to go out into the field. As we prepared to go, I said:

"Mr. Cowan, this visit has been specially interesting to me because it is so unusual to see one of your race doing business and owning property as you are. I am sure the example you set before your people must be worth a good deal. You are not only succeeding in business, but you are doing missionary work among your people."

"Mr. Root, I know what my people are, the greater part of them. There are men who come here and pick berries, and I have seen them work until they had earned perhaps twelve or fifteen dollars, and then I have seen these same men go and waste this money, or worse than waste it, in two or three hours' time. The saddest part of it is, they seem to feel no compunctions of conscience or regret, but start in to work, and do the same thing over again."

While my friend was talking I could not help feeling sad to reflect that it was not only the colored people who "spend money for that which is not bread, and labor for that which satisfieth not."

When I got out on the national pike I called on two more strawberry-growers. One of them told me how he had been growing berries a great many years, but had just made a discovery—in fact, had just got his eyes open so as to know how to grow berries profitably. He took me down a side hill to show me his new invention—another patch of Bubachs fertilized with our old friend Sharpless; and, oh such berries! not only in size, but in luscious sweetness; and I actually believe I would rather have the Sharpless berry for my own eating than any other berry grown. But, let us get to the new invention.

The plants were all put out last fall; and neither the Sharpless nor the Bubach had produced a very thick matted row. In fact, in some places there were not enough plants; but they had had good care, and each plant had an abundance of room so that it was growing great whoppers, even if there were not so many of them. This man sells the greater part of his crop by sorting out the largest ones and selling them at fancy prices. It is almost like growing berries in hills. The runners are kept off, or mostly off, as soon as a sufficient stand is secured for large berries. He does not get as many bushels per acre, but he gets better prices for what he does grow. A neighbor near him was managing a plantation a good deal the same way, but he was using the Brandywine. Here again we had great berries that could be tumbled about like potatoes, while the Bubachs in the same patch would be, many of them, too soft to handle before they were fully ripe. But I am afraid the Brandywine is not going to give us as many berries as the Bubach. The latter

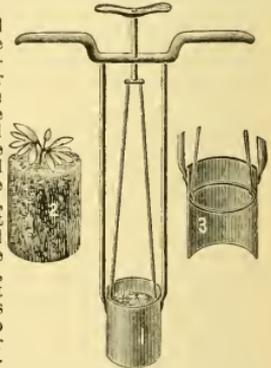

stands to-day, if I am correct, at the head of the list for large berries, and a lot of them. Some of the new varieties may get ahead of it; but introducers have been working hard for a good many years, and the Bubach seems to hold its own year after year.

A NEW TRANSPLANTING-MACHINE; ALSO SOMETHING ABOUT BASSWOOD-SEEDLINGS.

Something like two years ago a transplanting-machine was sent to Matthew Crawford, but for some reason or other he forwarded it on to me, asking me to test and report. On account of many cares, and other things to be looked after and tested, the little machine was laid under my desk until well along into the season before I took the trouble to take it out and try it. Another thing, I have tested so many machines that did not seem to be as convenient as some we already had in use, I was a little skeptical about it; but when I did get hold of it I was agreeably surprised to find that I could in a twinkling move any small plant to another location so quickly and so safely that it seemed almost as if it must be some sleight-of-hand performance.

The drawing will make the machine plain, almost without any particular explanation. You hold the machine in both hands, and with an auger-like motion back and forth you set the steel tube, No. 1, over the plant. It is pressed down till it will bring up the plant, roots and all, in a lump of dirt like No. 2. It is not advisable to push it any further down than is necessary to get all the roots. In fact, if the tap-root is broken off, with most plants they will do just as well.

After the plant is out of the ground in its ball of earth, you place your two thumbs on the lever at the top of the machine, and push down, releasing the ball of earth. With strawberries you can load these balls into a wheelbarrow, or with appropriate trays you can load them into a wagon. Fit your ground nicely, as described in our book on strawberry culture; mark it out according to your notion, then with the transplanting-machine make holes to drop your "potted plants" into, for they are potted plants, to all intents and purposes.

Some time in the fore part of April we put out with this machine several thousand strawberry-plants, including all the different varieties; and if there is one failure in the whole lot, I have not seen it. Almost any boy, with a little instruction, will operate it nicely; and with any soil that I have yet used it on, the dirt, if wet enough, will hold around the plant so it can be handled. The nicest way, in my opinion, is to grow your plants in a plant-bed made up of exceedingly rich compost; then you

carry enough of this compost out to the field to give your plants a big start, even if the ground is comparatively poor. We have not yet tried shipping plants by express, taken up in this way; but by breaking off a part of the ball of earth, so as to decrease the weight as much as possible, and yet have enough left to keep the roots perfectly, then packing these balls of earth with sphagnum moss, I think valuable plants could be sent this way with profit. The weight of the adhering soil would, of course, be a serious objection to sending any plants in this way unless it were a small number of something exceedingly valuable. Sometimes it seems desirable to swap places with certain valuable plants. With the above machine this can be done in a twinkling; and even the plants that have been transplanted do not seem to know they have been swapped. Although we have never used more than the one machine, I think it would be quite desirable to have another size a little larger; or two sizes might be found convenient. The one we use has a cylinder 3 inches in diameter and 5 inches in length. The whole thing amounts to the same thing as our transplanting-tubes; but you have no tin tubes at all to pick up and put away. The machine itself does the whole business.

Perhaps I should explain that cylinder No. 1 is made of the very best crucible steel; and while in use it is as bright as a dollar, and as smooth as a polished saw-blade.

And now we come to the unfortunate part of it. I have lost the letter from the man who sent the machine. I wrote him once, asking his permission to have an engraving made and have it published. He replied (I think it was about a year ago) that he was just about getting out an improved machine, and asked me to hold on a little. I have held on until I feel as if it would be wrong to keep people, who love gardening, any longer in ignorance in regard to this wonderful invention. It has now been tested by many competent men, and there is but one verdict in regard to it—it is way ahead of any other transplanting-arrangement of the kind that has ever been brought before the public. When our good friend gives me permission I want to make them and offer them at a reasonable price.

The little plant you see in the picture is a basswood-seedling. One day when one of our small boys was out of a job I told him to mark out one of our plant-beds with one of our markers (several times described), then pick up the basswood-seedlings all over the garden, wherever he could find them, and put them in the bed. No. 2 shows one of the basswood-seedlings just as we picked them up. In a little while he had a bed of 300 nice ones. And this reminds me that we have pretty much failed in getting basswoods to grow where we planted seeds; but wherever we are making up beds near the basswood-trees, these little seedlings come up plentifully. Under one small basswood-tree we picked out over forty plants. A friend suggests that perhaps the basswood-seeds should lie on the top of the ground, and endure the freezing and thawing through the winter; and he thinks that if, after this, we were to plant them in the spring, they would germinate successfully. Last fall, as you may remember, we planted something like a peck of seeds, but not more than a dozen plants came up out of all that quantity.

Will the friend who sent us the above machine, when this meets his eye, please let us know about it? I do not know whether it is patented or not; but the owner can, without question (in my opinion), procure a patent on it if he chooses.

#### FIRMING THE SOIL FOR STRAWBERRIES.

On page 691, Sept. 15, 1896, I spoke about the wonderful luxuriance of some strawberries at Matthew Crawford's. They were planted in a bed where the soil had been pounded down with a stamper, as you would pound the dirt around a post. Of course, the soil was first made fine and light, and plenty of manure was mixed with it. When I got home I had one of my plant-beds prepared in the same manner. It was spaded up very fine and soft, with plenty of manure mixed in. The ground was very rich, for plants had been grown on it for several years. After the fining-up it was pounded down as hard as the boys could stamp and pound it. It was so late in the fall that I did not see very much difference, and had rather forgotten about the matter. But it occurred to me a few days ago that each one of the four varieties on this bed was doing wonderfully. We have a new berry, the "Carrie"; another one called "Darling," and the "Earliest," the last of which I have been talking about. Each of the three is putting out runners that are just wonderful. A single strawberry-leaf will cover a teacup, and the stems stand up all of a foot high. The one called "Darling" has this morning, June 4th, the prettiest heap of fruit, ripe and partially ripe, I think I ever saw around a strawberry-plant.\* I began to think all three varieties were something wonderful in the way of luxuriance; and then it occurred to me about stamping the ground. Friend Crawford's soil is somewhat sandy, and I was thinking that perhaps it would do better on such ground than on our own. Where our plant-beds have been manured heavily for several years the ground has a tendency to get light so it dries out easily. I believe this stamping will correct this trouble to a great extent. Remember, however, that all the stamping and pounding must be done when the ground is dry and fine. Mash all the lumps; have the soil soft and fine for a foot deep or more; then pound it down as hard as you choose. Of course, out in the field we would roll it with a heavy roller and some heavy horses to pull it, and also to stamp it with their big heavy feet. But you can test the matter on a small bed, to show what compacting will do.

Our bed of Nick Ohmers and Margarets is just beginning to ripen, and they are little "peaches," without question. Mrs. Root was looking at them to-day, and she asked if almost any strawberry would not do wonders in a similar manner if I were to give it such rich soil and so much petting. Of course, we must allow for this. In the open field Michel's Early are just beginning to ripen. We shall probably make our first picking to-morrow morning, June 4. I do not think there is any other variety on our grounds that shows any ripe berries in the open field. In the plant-beds, where we kept off the frost by the use of glass, we are getting Marshalls, and have been getting them for two weeks past. The Jessies are also be-

\* This new kind has another peculiarity that makes it wonderfully attractive. When it begins to color it is a light rose pink—almost exactly like the blush on a peach; and the strawberry, when ripe, is of a pinkish red instead of a brick red; the shape is also almost perfect, and, taking it all in all, I do not wonder that the originator named it "Darling." To be fair, however, I must tell you that, out of six plants we obtained last fall for trial, one of them has not borne a berry; four of them produced fruit fairly; and it was only the fifth that gave us these little beautiful handsome berries that made me feel like saying, "O you precious little darling of a strawberry-plant!" In point of earliness I think it will be fully as early as the Michel, and next to the one called the "Earliest."

ginning to ripen in the beds where they had a little protection. You can hurry strawberries along very much indeed by covering them during severe weather; and a covering of cloth, while it protects the blossoms from frost, will also do quite a little toward making the strawberries ripen earlier.

#### CRIMSON CLOVER AT THIS DATE, JUNE 5.

Just before decoration day, people were stopping their teams to inquire in regard to the beautiful new plant that decked the field by the roadside; and when it came time to prepare bouquets for our national day, great crowds were begging permission to gather some of the heads. In this way it was paraded and shown and admired all over our county, and people have been coming constantly to see it. It is now a miniature sea of crimson, and it is certainly as heavy as any clover of any sort ever grown on our premises. In one of the agricultural papers I saw a criticism to the effect that it did not produce any such stand as the common red clover. Now, I don't think I ever saw any more clover of any kind on a piece of ground, unless it was at T. B. Terry's; and if he were to grow the crimson I do not know but he would make it come fully up to his red clover. But, dear friends, suppose the crimson clover does not give as large a stand as red clover. Please consider it is a catch crop, or a stolen crop, if you choose. The seed was sown after taking off that heavy crop of potatoes. The ground was not plowed at all—simply harrowed over hurriedly. The cost of the seed and fitting the ground was not more than \$1.50 per acre (say 75 cents for seed); and nothing more has been done to it till the present time. We are letting it mature seed in order that we may have not only home-grown but northern-grown seed to offer for sale.

There is plenty of time yet to plow it under, either for corn or potatoes. If the farmer should be short of feed, there is an immense lot of it that is equal to any clover known. It occupies the ground when the latter would otherwise be barren and useless. I believe, with the *Rural New-Yorker*, that, even if it winter-kills, it furnishes enough fertility to pay all the cost of seed and putting it in. To get it in after potatoes, I presume an early variety should be selected and planted early. Where our clover now stands we planted New Queen potatoes last year the 10th of May. They were dug somewhere between the 1st and 15th of September, and the clover was sown just as fast as we could get a strip through the field wide enough to cultivate. The potato-tops were used to mulch strawberries near by. Some of them were afterward scattered evenly over the crimson clover. We managed this without very much labor by throwing the vines off to one side, and, as soon as the clover was sown, throwing the same vines back again, taking pains to spread them over the ground evenly. Most of the clover has fallen over, or partially so, in consequence of its heavy growth. The bees are, of course, making a constant roar over the whole field. Two or three swarms have come out while the clover has been in bloom; and as it comes in just after apple-blossoms are gone, it hits the needs of the bee-keeper to a dot. If the clover is saved for seed it will furnish honey all through the interval between fruit-blossoms and white clover.

#### A NEW PLUM—THE PRIDE OF FLORIDA.

I send you to-day by mail a sample of a new plum, Pride of Florida. I send it to you because you are a lover of fine fruit, and because I hope to advertise it in GLEANINGS next fall, and wish you to know

that the claims I make for it are true. It is a seedling of the Kelsey plum, the earliest shipping plum, and a good bearer. The plums I send are from one-year-old trees, and have suffered in size from the long dry weather. AUG. LEYVAZ.

Francis, Fla., May 22.

Every one of the plums reached us in perfect condition; and just as soon as I tasted one it brought back old memories of finding plum-trees in the woods in my boyhood days. I showed one to Mr. Green; and before he tasted it he said, "This is an American plum, and it will grow just as well here in Ohio as in Florida." Of course, they are not very large, but they are perfect in shape and color; and in flavor I should put them ahead of many of the very large plums. They have something of the appearance of the sloe, but are considerably larger. I presume our friend means the trees bear fruit one year after being planted from the nursery. This seems to be, however, a good deal owing to the Florida climate. We should be satisfied if we got plums in two years.

#### THE NEW STRAWBERRY "EARLIEST."

*Friend Root*:—I notice you mention the Earliest strawberry in your May 15th issue as showing very early blossoms. Well, Mr. E. C. Green may be right. It may be all runners and no fruit in Ohio, but here during the past season it gave a fine lot of berries that (because of its earliness) sold at 15 to 20 cents per quart, while large fine berries a little later sold down to 50, 75, and \$1.00 per 32-qt. cases, and some of our growers could not sell them at all after paying picking. Our Earliest, we can say, for dollars and cents, has brought more money than any thing else, per acre. It is not the best berry, nor is it the most productive; but it is productive enough to pay well here. Don't let the plants stand too thickly. Give them a chance. It will (or does with us) do better the second year than the first. We shall be pleased to hear how it does with you, this year, any way. The Carrie has done nobly here this year. We shall just about cease picking Friday.

□ Rio Vista, Va., May 27.

M. T. THOMPSON.

All together this new berry pleases us so well that we have decided to put down runners and offer plants for sale. We can, perhaps, furnish a limited number by mail, say about the first of July. Some of the plants have furnished a pretty good lot of berries. The shape is perfect; the color is perfect also, but it is rather light. In flavor it is one of the very finest of the tart berries. The plant is a rampant grower. Those set out last fall have now a mass of foliage as large as a bushel basket. As I have said before, I think it will be a very nice thing to plant to a limited extent on account of its extreme earliness. With us it has been at least two weeks, in time of ripening, ahead of Michel's Early.

#### THE BELMONT OR GATE APPLE.

I hope you will follow it up and see if they are surely the same. I believe the genuine Golden Gate has smoky blotches on the skin. I consider the genuine old-fashioned Golden Gate one of the best apples on earth. I have been trying to get a tree to plant in my lot, but failed. Storrs, Harrison & Co. could not furnish it. I understood it did not grow well in nursery rows, and the best way to get it is to top-graft another apple-tree. I hope you will do all you can to revive this and the Rambo. Fruits of great merit should not be allowed to die out through neglect or inattention caused by newer things not so good. PHILoS. DILWORTH. □

Ingram, Pa., May 22.

#### A RATIONAL REMEDY FOR THE APPLE-TREE BORER.

I have protected my trees completely for 30 years from the apple-tree borer by wrapping the base of the trunk with any old cloth or carpet, or old feed-sacks, or cloth of any kind, putting them about 18 inches high, not too tight. They are held in place with strings. This does not hurt the trees, as about the second year the string bursts, and the rags, or

# A BICYCLE TOUR

Three gentlemen for a European tour purchased new hundred dollar bicycles. One a Columbia—the others of well-known high-grade manufacture. They had an agreeable trip—particularly the Columbia rider. Before returning to America, it being late in the year—and wishing to buy new machines in 1897—they sold their wheels to a London dealer. The Columbia bicycle brought \$65.00. The others \$40.00 and \$35.00 respectively. But one of the many proofs of Columbia superiority. If you look a year ahead there is wise economy in

*Columbia*  
Bicycles

\$100 TO ALL

## Look Here!

Do you need queens? the purest and best. If so, we are prepared by return mail to ship the 3 band and golden Italians, and silver gray Carniolans, untested, warranted purely mated, for 50c; tested, 75c; breeders, \$2.25.

JUDGE E. Y. TERRAL & CO., Cameron, Texas.

# BEES QUEENS

Smokers, Sections, Comb Foundation, And all Apianian Supplies cheap. Send for FREE catalogue. E. T. FLANAGAN, Belleville, Ill.

## What More?

**GUARANTEED**  
Queens from best working stock.  
Reared by best methods.  
Cells and queens selected.  
Poor queens replaced free.  
20 years' experience—7 as a q. breeder.  
7c; six, \$3.50; twelve, \$6.50.  
Promptness.  
Safe arrival.  
Free catalogue.

J. B. CASE, Port Orange, Fla.

## QUEENS BY RETURN MAIL.

Daughters of best imported queen mother, warranted purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded.

L. H. ROBEY, Worthington, W. Va.

**BIG WONDER!** The Smoke Engine goes without puffing; burns in the center; heats only the top; burns chips without drizzle; makes all the smoke wanted, without work; the best bee-smoker ever made; doesn't tip over.

T. F. BINGHAM, Farwell, Mich.

## WEED DRAWN FOUNDATION.

We have been compelled to disappoint a good many who have ordered a supply of drawn foundation. Our machine was finished for a strip only two inches wide, and that not as perfect as we wanted to make it. A mishap occurred to the dies, making it necessary to repair. In doing so we have made them over new, a-d full size, 5 by 8 inches, and they are almost completed. We expect to have the machine running by the time this number is mailed. We have a number of orders waiting; but with increased capacity of the machine we hope to be able to supply promptly all that will be needed from now on for experimental use this season. If you have not seen any, and wish to try it, send on your orders. Pieces 4x8 inches (or 2 4x4), 5c each; 6 for 25c. A box of 1/2 lb., 75c, or prepaid for 90c. There is still time to give the drawn foundation a good test this season.

## BUSINESS STILL BOOMING.

There is very little let-up on orders yet; and as the season advances the demands for immediate shipment become more imperative. We are in a little better shape than we were June first, but are still several days behind. If this week does not bring too many new orders we hope, by the end of the week, to have almost all orders filled. We continue to send out three full carloads a week, besides the multitude of smaller orders. We are shipping this week the ninth carload for the season to Jos. Nysewander, Des Moines, Iowa, and the fourth car to Syracuse, N. Y.; have shipped the fourth car to St. Paul, and also to Chicago; the third to Geo. E. Hilton, Fremont, Mich., and the first to Byron Walker, Ewart, Mich. We have also shipped a carload to L. A. Watkins Mdse. Co., Denver, Colo. Our records show that, up to this date, we have shipped over fifty full carloads this season, while up to the same date last year we had shipped forty cars. We are still running night and day, and are likely to continue the rest of this month, from present outlook.

## KIND WORDS FROM OUR CUSTOMERS.

## ROOT'S CATALOG.

A short time ago I had occasion to look over your catalog more closely than usual. I read a few paragraphs here and there; and the more I read, the more I was interested in its contents, until I had the whole pretty well perused. It is not only a catalog or price list, but it is a veritable bee-keeper's cyclopedia. It contains a little of everything, and that "little" seems to be the cream of all bee-literature. It contains more matter of real value on its few pages than some 300-pare volumes. I am surprised that we have not before realized its worth, or, if we have, have not mentioned it. There is hardly a question in the line of apiculture that the pamphlet does not answer in some way. Its condensed information makes it valuable, not only to the amateur and professional bee-keeper, but to every one who is the least interested in bees. I should not consider a library complete without it.

Naples, N. Y.

G. C. GREINER.

Mr. Root—Yours was a kindly, generous thought, to send out potatoes to your GLEANINGS family; and when the nice new barrels came so promptly, filled with choice potatoes, it was too much, and we hoped it might be returned to you, "in basket and store," pressed down, full, and running over, for many years.

Mt. Carroll, Ill., June 9.

LIZZIE HURLEY.

My dear friend, you do not know how your letter softened up some of our faces, and brought a smile to the face of one overworked faithful clerk. We had just been trying to untangle a snarl because two barrels of potatoes got "swapped," in our hurry in

getting off over 500 bushels of premium potatoes in a little over a week. The two barrels of potatoes that got swapped contained other things of value, which made the matter more complicated. After some search among the records, overhauling the clerks, etc., I uttered an exclamation when I picked up your letter. The clerk mentioned said, "Oh dear! I hope it is not another mistake." In reply I handed her your brief but kindly epistle. Had you seen her face soften you would have felt amply repaid for your kind words. May God bless you for them. Such letters are sometimes like glimpses of oases in the desert of business, especially when business is rushing and crowding until almost everybody is overworked.

## Single-tube Bicycle Tires.

Good ones, too, for

\$5.00 Per Pair.

Including repair kit and pump. We have given them a thorough test and find them well made and durable.

## IF YOU WANT BEES

that will just "roll" in the honey, and that are wonderful red-clover workers, also gentle to handle and exceedingly hardy, then try **MOORE'S STRAIN OF ITALIANS**, the result of 18 years of careful breeding.

Warranted queens, 75 cts. each; 3 for \$2.00; or doz., \$7.50. Select warranted, \$1.00. Safe arrival and satisfaction guaranteed. Circular free. Those who have never dealt with me I refer to A. I. Root, who has purchased of me over 850 queens.

J. P. Moore, Morgan, Pendleton Co., Ky.

## For Sale.== Bees and Queens.

Queens, \$1.00. Bees by the pound, \$1.00. Nuclei, two frames, with queen, \$2.50; one frame, \$2.00. Also Barred and White P. Rocks, Silver Laced Wyandottes. Eggs for sitting, at \$1.00 for 15.

MRS. A. A. SIMPSON, Swarts, Greene Co., Pa.

## BEES FOR SALE.

In 8-frame Dove-tailed hives, queens from imported mothers. Price \$3.00 to \$4.00 per colony.  
EDW. SMITH, Carpenter, Ill.

## Gleanings at Reduced Rates.

With a view to encouraging membership to all kinds of bee-keepers' associations whatsoever, local or otherwise, we have decided to offer **Gleanings** at 75 cts. per name to members of such organizations. Old or new subscribers may take advantage of this offer; but in the case of the old, all back subscriptions must be paid up before the 75-cent rate for a year will be allowed; otherwise only 9 months will be credited.

We must either require all subscriptions at this reduced rate to come through the secretary, or we must have evidence of some sort that you belong to some bee-keepers' society. Simply a line from the secretary, stating that you are a member in regular standing, will suffice. At your next annual meeting, bear this in mind; and if you wish to become a subscriber to this journal, hand 75 cents to your secretary, and when that amount is received by us your name will be placed on our subscription list for 12 months.

If you do not now belong to any association, send \$1.75 to us or to Secretary Dr. A. B. Mason, of the United States Bee-keepers' Union, at Toledo, Ohio, Station B. This will entitle you to a year's membership and protection in the Union, and one year's subscription to this journal.

**The A. I. Root Company,**  
Medina, Ohio.

### BUY DIRECT

and pay but one profit. Our assortment is one of the best and most complete in

**FRUIT and ORNAMENTAL TREES, SHRUBS, PLANTS, ROSES, VINES, BULBS, SEEDS**

Rarest new, choicest old. Send for our catalogue to-day; it tells it all; an elegant book, 168 pages, magazine size, profusely illustrated, free.

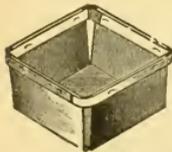

Seeds, Plants, Bulbs, Small Trees, etc. by mail postpaid, safe arrival and satisfaction guaranteed. Larger by express or freight. 43d Year. 32 Greenhouses. 1000 Acres'

### Confidence Restored.

Not **Page** confidence, that was never lost. Sales increased every year through the late "unprosperousness." Now comes 35 per cent increase for the month of April. This shows that people like the **Coiled Spring** and like to buy it of the owner, rather than those who attempt to appropriate it without leave or license.

**PAGE WOVEN WIRE FENCE CO.,** Adrian, Mich.

In writing advertisers please mention **GLEANINGS.**

### ONE MAN WITH THE UNION COMBINATION SAW

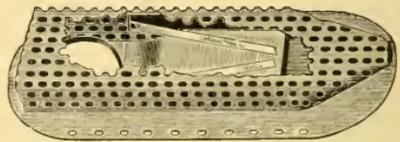

Can do the work of four men using hand tools in Ripping, Cutting off, Mitering, Rabbeting, Grooving, Gaining, Dadoing, Edging up, Jointing Stuff, Etc. Full Line of Foot and Hand Power Machinery. Sold on Trial. Catalog Free. 1-24ei

Seneca Falls Mfg. Co.,  
44 Water St. Seneca Falls, N. Y.

**The King Windwheels.** Only 1 inch thick edge-wise. Six-foot wheel does all general work. Weight of wheel 61 lbs. Latest and highest standard of excellence. Best of galvanized towers. Write to day for full information to

C. O. WEIDMAN, Sole Mfr., Medina, Ohio.

### Porter Honey-House Bee-Escape.

Have you seen it? Just the thing to put on the doors or windows of your bee-rooms. Indispensable, you'll say, after you have tried it.

Price by mail, 25 cents.

### Cowan and Novice Extractors.

These are the best. We are prepared to furnish on short notice, from any of our several branches, 2, 4, and 6 frame Cowans, and 2-frame Novices.

If you want the genuine, see that they bear our name.

A 36-page catalog sent free on application.

Next Annual Meeting at Buffalo, N. Y., Aug. 24—26, 1897.

Honey Column.

CITY MARKETS.

SAN FRANCISCO.—Honey.—Fancy white, 9@10; No 1 white, 8@9; fancy amber, 7; No. 1 amber, 6@7; fancy dark, 5@6; No. 1 dark, 4@5; white extracted, 4 1/2@4 1/4; amber, 3 1/2@3 3/4; dark, 2@3; beeswax, 24@25. Honey crop is of unusually fine quality, and yield is fairly large. The demand is not active, and apiarists are unwilling to sell at prevailing prices.

HENRY SCHACHT,  
 San Francisco, Cal.

June 14.

CHICAGO.—Honey.—Not any new comb honey on the market. Some new extracted is offered without sales of consequence, yet those effected are such as to establish a decline of half a cent per pound from our previous quotation. Beeswax without special change.

R. A. BURNETT & Co.,  
 163 So. Water St., Chicago, Ill.

June 24.

NEW YORK.—Honey.—No comb honey on our market. Some demand for white comb at 10@11. Extracted is arriving freely from the South, and selling fairly well at 50-52c per gallon for average grade, finer grades at 55-60c per gal. New California is beginning to come in, and sells at 4 1/2@4 1/4 for light amber, and 5 1/2@5 1/4 for white. Beeswax in fair demand at 26@27.

HILDRETH BROS. & SEGELKEN,  
 120-122 W. Broadway, New York.

June 22.

MILWAUKEE.—Honey.—The supply of honey in this market continues to hold out equal to the demand, although the choice quality is getting reduced, and the demand exists for such, while the common and poorer grades are hard to move at any price. Can quote white choice 12@14; white common, 10@11; dark, 8@10; extracted white, in barrels and half-barrels, 5 1/2@6 1/4; ext. amber, in barrels and kegs, 5@5 1/4; ext. dark, 4@4 1/4; beeswax, 25@27.

A. V. BISHOP & Co.,  
 Milwaukee, Wis.

June 23.

KANSAS CITY.—Honey.—Fancy white, new, 13@14; No. 1 white, new, 12@13; fancy amber, new, 11@12; No. 1 amber, new, 10@11; fancy dark, new, 9@10; No. 1 dark, new, 8@9; No. 1 white, old, 10@11; No. 1 amber, old, 8@9; No. 1 dark, old, 7@8; extracted white, old, 5@5 1/4; amber, old, 4 1/2@5; dark, old, 3 1/2@4; beeswax, 25@30.

C. C. CLEMONS & Co.,  
 423 Walnut, Kansas City, Mo.

June 22.

PHILADELPHIA.—Honey.—Old comb honey mostly cleaned up. Odds and ends sold at any reasonable offer. Very little new in yet—not enough to establish a price, and will be no call till September. Extracted dark, 3 1/2@4; amber, 4@4 1/4; light, 5@5 1/2. Prices will rule low; big crop everywhere. Beeswax, 25.  
 W. M. A. SELSER,  
 June 22. 10 Vine St., Philadelphia, Pa.

CLEVELAND.—Honey.—Fancy white, 12@13; No. 1 white, 10@11; fancy amber, 9; fancy buckwheat 6@7; beeswax, 28@30. Honey is moving very slowly.  
 A. B. WILLIAMS & Co.,  
 June 21. 80-82 Broadway, Cleveland, O.

CINCINNATI.—Honey.—There is a fair demand for extracted honey at 3 1/2@6, according to quality. Demand for comb honey is slow at 8@13. Considerable new extracted honey has been arriving for the past two or three weeks, and finds a pretty ready sale. Demand for beeswax is fair at 22@25 for good to choice yellow.  
 CHAS. F. MUTH & SON,  
 June 22. Cincinnati, O.

BOSTON.—Honey.—Fancy white, 13; No. 1, 11@12; No. 2, 10; white extracted 7; amber, 5@6.  
 E. E. BLAKE & Co.,  
 June 25. 57 Chatham St., Boston, Mass.

ST. LOUIS.—Honey.—Fancy white, 12@12 1/4; No. 1 white, 11@11 1/4; amber, 9@10 1/4; extracted amber, 4 1/2@4 1/4; white, 4 1/2@5 1/4; beeswax, 25 1/2@26. We quote you nominal price of honey. Not much being sold at present, and what is, is a speculative way.  
 WESTCOTT COMMISSION CO.,  
 June 26. 213 Market St., St. Louis, Mo.

DETROIT.—Honey.—Fancy white, 10@12; No. 1 white, 10@11; fancy amber, 8@9; No. 1 amber, 7@8; white extracted, 5@6; amber, 4@5; beeswax, 25@26.  
 M. H. HUNT,  
 June 25. Bell Branch, Mich.

COLUMBUS.—Honey.—Very limited demand for honey. No new crop on the market, but expect small lot next week. Do not look for very good prices. White clover selling at 12 1/2@13; amber, 7@8.  
 THE COLUMBUS COM. & STORAGE CO.,  
 June 23. 409-413 N. High St., Columbus, O.

MINNEAPOLIS.—Honey.—Best white-clover comb honey, 14; amber, 10@12; water-white ext., Wis., 6 1/2@6 3/4; amber, ext., Wis., 5@5 1/2; Cal. water white, 6@6 1/2; Cal. amber, 5@5 1/4. Market nominal.  
 S. H. HALL & Co.,  
 June 22. Minneapolis, Minn.

FOR SALE.—Fancy extracted in 60-lb. cans, and fancy comb (Danzy sections) mangrove honey in 30-lb. cases. Cash offers wanted, f. o. b. here.  
 H. PRICE WILLIAMS, Miami, Florida.

Italian Queens, either golden beauties stock, 90c each; imported, 55c each; 6 for \$3.00. One tested queen to new customer, 50c; breeders, \$2.00 to \$3.50 each. P. O. M. O. office, Lavaca.  
 E. A. SEELEY, Bloomer, Ark.

QUEENS, Pure Italians, 3 or 5 banded, tested, \$1.00; untested, 50 cts. I have 500 nuclei. Can send queens by return mail.  
 DANIEL WURTH, Falmouth, Rush Co., Ind.

Tested By mail, in July and August, 60 cts. each.  
 Italian Queens J. C. Wheeler, Plano, Ill.

Headquarters for Red-clover Bees. Tons of honey are what they are gathering now. Queens wholesale and retail. One queen, 50c; 3 for \$1.25.  
 G. RUTZAHN, Menallen, Pa.

WARRANTED Three and Five Banded Italian Queens at 50 Cents each.  
 GEO. W. COOK, Spring Hill, Kan.

# What Has Been Told Lately

In the *Bee-keepers' Review*? did you ask? Well, in the Jan. issue Mr. Aspnvall explained a simple plan whereby the mating of queens at the home yard may be secured with almost *absolute certainty*. R. L. Taylor, in the February issue, describes an experiment made to determine if honey stored in the super of a foul-broody colony was infected with the germs of foul brood. In the March number, Isaac Lundy told "How to Get Drawn Combs right in the Sections, and Secure Comb Honey at the same Time." In the April issue, R. L. Taylor tells at what a high temperature he kept his bee-cellar last winter, and the results. The June issue contains a long article from Mr. Lundy, explaining his methods, and giving the details of a plan whereby he secures drawn combs during the white-honey harvest. Of course, there are other articles, editorial comments, extracts, notes from foreign bee-journals, Hasty's "View of Current Bee Literature," etc.

The *Review* is \$1.00 a year; but for the sake of getting new subscribers I am offering it for 1897, and 1000 first-class sections, for only \$2.50; or the *Review* and a Bingham Conqueror smoker for \$1.75; or the *Review* and a fine tested Italian queen for only \$1.50

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4-inch Smoke Engine too large. January 27, 1897. Truly, W. H. EAGERTY, Cuba, Kansas.

**T. F. BINGHAM, Farwell, Michigan.**

# A Penny Saved is a Penny Earned.

Yes, it's better than that, for the saved penny you don't have to earn twice. Well, the **Weekly American Bee Journal** will help you save your pennies. It is a real money-saver to the bee-keeper who will read and practice its teaching. The regular price is \$1.00 a year, or only about two cents per copy. But in order that new readers may give it a trial we will send it for **only 50 cents from the time we receive your subscription to the end of 1897.** Now, the sooner you send the half dollar, the more copies you will receive. Send in stamps if more convenient. Sample copy free.

**GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.**

# GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED  
SEMI-MONTHLY  
Published by THE A. ROOT CO.  
\$1.00 PER YEAR MEDINA, OHIO.

Vol. XXV.

JULY 1, 1897

No. 13.

## STRAY STRAWS

FROM DR. C. C. MILLER.

WHEN NIGHTS ARE SO HOT one can't sleep, bees seem to get in their best work.

WHAT SIZE should starters be in sections? is asked in *American Bee Journal*. Three of the 21 repliers want small starters, the rest full sheets.

I'M RATHER GLAD friend Thompson's figures as to economy of making one's own foundation are countered on page 446. I'd rather not believe it's cheaper to make my own foundation. Don't want the bother and worry of it.

NEVER BEFORE, I THINK, were railroad rates so low to a big bee convention as to the Buffalo convention, Aug. 24—26. As attendance is generally in proportion to cheapness of travel, this ought to be the biggest convention we have ever had.

F. L. THOMPSON is right, page 445, in thinking you can't drain the liquid part from all kinds of granulated honey. It's only that with coarse grains, and T. F. Bingham thinks it can be done in no case with properly ripened honey. Possibly that's true.

JUNE 9, No. 156 was unqueened. June 15 it had an egg in a queen-cell. Where did that egg come from? Had it remained there 6 days without hatching? or was it the product of an aspiring worker? I incline to the latter view—have had several such cases.

WHEN YOU HAD such a tough time with that swarm, Ernest, p. 458, didn't it meander along your backbone that it might have been better to have had the queen clipped? [Yes, if we were not selling queens right along we would clip all our queens after they were laying. See editorials; also Doolittle's article.—Ed.]

N. E. FRANCE, the Wisconsin Foul-brood Inspector, writes *American Bee Journal*. "I find many Wisconsin bee-keepers who did not know

their bees were diseased, and nearly every case is where they do not take a bee-paper." May be one section of a foul-brood law ought to compel every bee keeper to take a bee-journal.

IT IS POSSIBLE that the Monnier treatment for paralysis, page 447, had nothing to do with the cure. It is also possible that it had every thing to do with it, and it is so easily tried that many ought to report as to its efficacy within the next two months. Won't some of you paralytically, for the general good, try it, and promptly report success or failure?

IN REPLY to your question, p. 441, Mr. Editor, R. Wilkin wants a term that in one word comprehends the hive with its contents—bees, combs, and all. What word have we now for that? [There is no term covering such an idea. Perhaps "stock" would come the nearest to it. This term is sometimes used in the sense above described, and sometimes applying in a sense to the bees only.—Ed.]

THE FEW LINDENS to be found here are doing better than your Medina trees. Most of them are loaded with blossom-buds. [I hope your basswoods may more fairly represent those over the country generally. It would be worth much, if we could know the probable prospects from basswood over the country. If no bloom is to be expected, then this will have a tendency to stiffen prices a little on white clover.—Ed.]

IT LOOKS STRANGE to see supers nearly filled with honey, and no sealed honey in the brood-frames; but that's common this year. Strong colonies and a sudden flow of great abundance. [We do not find that condition here at Medina. I suspect the reason is, that our home apiary is overstocked. We are this week starting an out-apiary to give some relief to the home yard. Later.—Yard is located. Bees at the out-yard are doing better than at the home yard.—Ed.]

AN UNUSUAL FEATURE of swarming this year is the very little preparation made in advance. The old rule, that the swarm issues when the first cell is sealed, is utterly ignored, and in most cases queen-cells have only eggs. It may

be different later. Possibly it may be accounted for by the change within a week from very cool to very hot weather, and from the point of starvation to a flood of honey. [There are some other unusual features about swarming this year. See editorials.—Ed.]

PROFESSOR COOK is right, page 449, and he's wrong. We ought never to have had two organizations, and we never would have had them if he and the other members of the old Union had understood correctly. But when amalgamation was killed, there was nothing left but to start the new organization. If wise counsels prevailed there would even yet be a union of the old Union and the new Union. [Many of us hope that wise counsels will yet prevail.—Ed.]

TRANSFERRING 21 days after swarming is perhaps better than during fruit-bloom. [Yes, perhaps; but during fruit-bloom there is very little honey in the combs, comparatively. Twenty-one days after swarming the combs may be crammed full. I have transferred a good many colonies after the honey-flow, and it was no pleasant job. It also occurs to me that, 21 days after swarming, robbing would be bad, and cutting up combs filled with honey would only aggravate matters. During fruit-bloom, combs would be comparatively light, and bees would be busy on fruit-blossoms.—Ed.]

THERE! I'm glad we have a standard set for rapid section-folding—1000 in 40 minutes. But, say, that girl has the advantage of long and exclusive practice, and common people needn't be discouraged at 1000 or less in an hour. Now give us a mark to aim at in using the Daisy foundation-fastener? How many starters does your expert put in in an hour! [Our people have never timed themselves on starting sections; but a fair average speed is about 500 an hour. They say they could do it a little faster, but never tried to see what they could do at their best.—Ed.]

THE A. I. ROOT Co. will take hold of a uniform honey-package if some organization will. Page 444. Why wait for some organization? But I suspect there was a shortage of "nots" in the printer's case when he set that sentence. [You are right, doctor. One little *not* was inadvertently omitted. I tried to say if no one else would take hold of the cheap extracted-honey package the A. I. Root Co. would. But we do not care to do so unless the demand is made sufficiently strong to warrant us in laying in stock at our branch offices and agencies.—Ed.]

JOHN MCARTHUR, in *American Bee Journal*, thinks it is ridiculous to describe the markings of workers and not of queens and drones. It does seem a little so, but I couldn't give a distinct description of an Italian drone; and while belaboring me for my ignorance he fails to give

such description himself. [The fact of the matter is, that the color of the drones and queens may vary all the way from black to a light yellow in very pure stock. On the other hand, workers themselves must show uniformly three yellow bands. When these three show, the other characteristics are present. Some of the blackest queens we ever had, produced uniformly nicely marked three-banded Italians. The drones from one of the best breeding-queens we ever had were almost black.—Ed.]

THE *Bee Master* is the name of a new bee-journal published in England. It makes the unique statement that it has no editor, and its columns show it; for a good editor would not allow so many abusive personalities. It is for Punic bees and against the *British Bee Journal*. [While nominally there may be no editor to this new bee-paper it is pretty evident that John Hewitt is the presiding genius. The fact of the matter seems to be that this gentleman is sore over the fact that the *British Bee Journal* and GLEANINGS said some plain and truthful things about Punic bees. Having started a journal of his own he is again extolling the merits of Punic bees—a variety that is cross and bad propolizers, with hardly a redeeming quality.—Ed.]

AIKIN AND YOU, Mr. Editor, don't agree as to the advisability of selling consumers candied honey. I'm with Aiken. C. F. Muth has for years had his customers educated to demand candied honey. Suppose you sell it liquid. Before it's half used up it candies; and the customer, knowing nothing about properly melting it, considers it spoiled, and doesn't want any more honey. Wouldn't more honey be sold in the long run if it were sold granulated, and people instructed what to do with it? [Aikin may be right for his class of trade, especially if he has educated his customers up to the idea of candied honey; but the general run of consumers do not take very kindly to candied honey. The retailers nearly all say that the honey should be liquid, and kept so. Mr. Chalon Fowls, M. H. Tweed, and numerous others, hold to this idea. They visit the grocers selling their honey, and any bottles containing honey candied, or partly so, are exchanged for those that are liquid. *Later*.—After writing the above, J. A. Buchanan, who retails so many carloads of honey, says Aikin's idea "looks well on paper, but in practice it is different." He promises to write an article explaining his position more fully.—Ed.]

CONFLICTING TESTIMONY as to foundation without papering comes from two southerners, p. 453. Now, whose testimony shall be taken—that of the man who, without saying he has tried it, says it *would* get matted together, or of the man who says he tried it and it *didn't* get matted together? This week I used brood

foundation made five years ago, kept in boxes without papering, standing through one summer where the sun shone through the window directly on the boxes, and it was as good as ever. (Since those items were published in regard to papering we have received a letter from a customer in the South, who, having ordered the foundation unpapered, reports back that some of the sheets stuck together. We have hardly dared not to paper unless we have received special directions to the contrary. It makes lots of extra work in unpapering, and if it could be dispensed with it would save one extra automatic attachment to our machine, for the great bulk of our foundation is now all papered by machinery. So far as we are concerned, it makes very little difference whether we paper or not. If I were in the North, however, I think I would order all my foundation unpapered. In the South it might make trouble to leave the paper out.—Ed.)

*Bu R. C. Aikin.*

#### BEES EVAPORATED; A NEW MALADY.

In the spring of 1891, when I had the care of Mr. N. C. Alford's apiaries at Fort Collins, Colo., I had an experience that I had never heard the like of before nor since until the past spring.

The bees I had charge of were in three apiaries—one in town, and two about seven miles out. The out-apiaries were about  $1\frac{1}{2}$  miles apart—one on the river-bottom, and the other a mile or so from the river. It was my custom in the spring to go to each apiary about once in two weeks or thereabouts, my visits becoming more frequent as the season advanced to near the honey-flow. The books in which I made the records were, of course, left with the proprietor when I left his employ in the fall of 1891, so I shall have to speak from memory and approximate the dates, etc.

I had been watching carefully the progress of brood-rearing, and had the colonies quite strong in both bees and brood. The bees had been packed in chaff, and all in ten-frame hives. Many colonies were so strong that they were clustering out, although we had not unpacked yet. This was in May. While they were so, I had looked all over and equalized stores and brood, then was absent about ten days, I think. About the last days of May or first of June I went to the out-apiaries to again

inspect as to stores, remove packing, and do such work as would guard against swarming. I had not noticed anything wrong at the home apiary, nor any very marked features indicating wrong conditions at the first apiary visited; but when I reached the river apiary, and began to look at the hives, I was astonished at the very few bees in them. I went to some hives that I knew had been clustered out about ten days previously, and I found not enough bees to cover the brood. The weather was warm, the bees packed in chaff, and the few bees left were spread all through the hives caring for the brood. The weather was so warm that there was no loss of brood; and as they had from four to seven combs well filled, the hives were soon very populous again.

My employer said the high winds had blown the bees into the river. The stream is only a small one, from 10 to 25 feet wide. The other apiary,  $1\frac{1}{2}$  miles away, showed some loss too, as a careful inspection showed, though, as I said before, it was not so marked as to call special attention to it until I had visited the river apiary. There was also another apiary some three miles away that the owner said was afflicted in the same way. Some of the colonies were so depopulated that, when I lifted combs, I could lay my open palm on the face of a comb of brood and scarcely touch a bee. It was not what I understand as spring dwindling. The bees were mainly young, for bees had been hatching for weeks. At the time, I doubted the loss being the result of winds, though I could not account for it in any other way, so I said little or nothing more about it, because others said it was the wind.

From the above experience until the last spring (1896) I did not see or hear any thing more of the trouble; but the apiarists about Denver had a rather vivid experience last spring, that brought the matter up in a very serious light.

At the annual meeting of our State Association that met in January we had arranged to hold a spring meeting. In arranging dates through the executive committee I was in correspondence with Mr. Frank Rauchfuss—our secretary—who lives near Denver. I live 50 miles north of Denver. Mr. Rauchfuss reported that he thought it useless to do any thing toward a meeting, for all the bee-keepers thereabout were completely discouraged, because their bees were nearly all dead. However, we went ahead and had a meeting, although but few came out, and they all had the blues.

The trouble about Denver covered a diameter of fifteen or twenty miles, as nearly as I could find out. The Rauchfuss Brothers are good apiarists and close observers, and they told me the trouble came very suddenly. I think they said it lasted only three or four days. The time, I think, was about the middle or last of

May. There were many hatching bees, and brood in three to five combs. The bees just vanished, and were nowhere to be seen. If they had died in or about the hive, possibly we might have found out what was the matter; but they seemed to evaporate, hence I have called it "evaporation." The trouble this time was more sweeping and disastrous than in my experience in the spring of 1891. The loss of bees was so complete that many colonies had not half a teacupful of bees left, where, less than a week before, they covered brood in three combs and upward. The queens, it seems, were always left; but the workers so completely evaporated that the brood perished. The Rauffuss Brothers reported they had over 200 colonies, and there were not enough bees left to make 25 good ones. All apiaries were not alike affected—that is, to the same extent. I saw but one of the apiaries affected (the malady did not extend to my territory), and that was a few colonies that Mr. W. L. Porter had in North Denver. Those few colonies had three to five times more brood than they could care for. In fact, they were so very weak that it was only the most favorable weather that would enable them to pull through, and this was about the second week of June.

As I said of the experience I had in 1891, many said it was high winds. Others said it was the smelter smoke that killed them. It was just as windy at Loveland, and in badly affected districts protected apiaries were as bad off as unprotected ones. Then, too, it hit hard where the smelter smoke did not go, and places it did go were "O. K." It seems that it could not be accounted for by fruit-bloom spraying, either, though it occurred about that time. It remains yet a complete mystery. Should it strike a whole State as it struck Denver last year, the consequences would be almost annihilation of the bee-business. I hope our Colorado apiarists will be on the lookout this year to watch the trouble if it should appear.

*Later.*—Since writing the above the Colorado State Association has had another meeting. I understand the new disease, or whatever it is, was largely discussed, but I believe without any definite results. Paralysis has been more or less in Colorado, but I can not think this trouble is the same. I have several times had some loss of bees in May, especially if there came a cold rainstorm. Bees would bloat, and crawl out and die about the yard, many getting from twenty to thirty feet from the hive, jumping and hopping in their effort to fly. Some call this "Hoy sickness." It comes about the time of apple-bloom. I had one colony that was afflicted in this way last year, and it did not get over it for a number of weeks.

Before this is published I may possibly learn more of these matters. I hope to see many of the apiarists in Colorado in April and May—at

least by May; and as I shall be going by wagon I shall have some opportunity to gather information.

Loveland, Colo.

[What you have described does indeed seem to be a new sort of disease—at least I never heard of it before, or at all events where the malady seemed to be so destructive and far-reaching. At two different seasons in our own apiary we noted quite a loss of the workers. Examination of the grounds showed that hundreds and almost thousands of workers with defective wings were flying about, and crawling up blades of grass. The bees were not bloated nor distended, and were apparently perfect in every respect save the wings. I believe I am quite familiar with bee-paralysis, and I feel very certain that it is nothing of this order. It is possible that what I have described was a milder form of what appeared about Denver. In our own case we could scarcely account for the trouble—at least, why the wings of the bees should be defective. It is possible that a peculiar kind of flora tore the wings as the bees went in and out of the blossom in quest of honey or pollen. I should be glad to have our readers report any similar cases that may have come under their notice. By comparing notes we may be able to determine what the trouble is.—Ed.]

---

#### RULES FOR GRADING HONEY.

THE IMPERFECTIONS OF THE ACCEPTED GRADING; CRITICISMS AND SUGGESTIONS.

By J. E. Crane.

On page 157 of GLEANINGS, W. A. H. Gilstrap says, "I never heard of a half-crop of honey in this valley that was *actually* water-white, or that had sections actually unsoiled by bees. I hope grading-rules will not be among the *impossibilities* next season." I have underscored the last sentence in this quotation, and will use it as a text for a short discussion of that already much-discussed subject, *Grading*.

□ The bee-keepers of this country were two or more years in discussing and making rules for grading; and now we have had two or more years in which to practice these rules; and our bee-journals have certainly done their duty in trying to enforce them or bring them into general use. May it not be well, before another crop is gathered, to inquire what have been the results, what the advantages to bee-keepers, what the defects, if any, in those rules? And yet very few, I fear, will care to stand up and express their dissatisfaction, however they may feel, with these rules adopted by the assembled wisdom of the American International Bee-keepers' Association; yet Mr. Gilstrap gives us to understand that those grading-rules are among the impossibilities. He does not say they are impossibilities, but hopes rules will be adopted that are *not* impossibilities.

For one I should like to know how many bee-keepers have tried to grade exactly by those rules, and their success. How many dealers

bought and sold honey graded accurately by those rules, and their experience?

Experience-meetings are often of value. The last year we had an unusually fine crop of honey in this section, and I said to myself, "I will try to grade my honey just right if I can. I even cut out the rules, as adopted by our International Association, from one of our journals, and tacked it up on a door close by where I was at work, that they might be handy to refer to often, as I was in doubt. Let us see how it worked.

I pick up a section. It is unsoiled, either wood or comb; is of even thickness, and comb to wood attached all right; but, alas! it is not "Fancy," for a dozen cells on one side, inside of the outside row, at the bottom, are unsealed! It does not matter that the outside rows on both sides of the comb are nearly all sealed; those unsealed on the next row from the bottom condemn it.

I next handle a section that seems all right; but, hold! the separator was a little warped, and the comb is not exactly of even thickness. Not one person in twenty would notice it; but a bee-keeper will, and it must be thrown out.

Again, I find a section that fills the bill; but, again, I am disappointed; for on one side, near the bottom, a little brownish tint shows travel-stain. This section will not even answer for No. 1, for is not No. 1 to be without travel-stain? And yet I would as soon place this comb on my table as any other, even if President McKinley were my guest.

I pick up another section; and, while the comb is faultless, the section is a little stained with propolis. The propolis has been removed, but it does not look "unsoiled." This must not be labeled No. 1. Let us be accurate.

The next comb proves a great success. It is "Fancy" in every respect. We are more hopeful. We shall yet have a few cases of real orthodox "Fancy;" but the very next comb, although otherwise all right, has two little cells with their eyes open, inside of the row next to the wood. Half the cells next the wood are sealed; but nothing is said about that in the rules, and we are going to grade our honey by rule. So this section is not fancy—only No. 1.

Again we try it, and are rewarded in finding one or two fancy combs with another equally good; but a small knot-hole in the separator caused a little bulge on one side of the comb, while another is "just a little" soiled on one side by the very industrious Italians bringing up cappings from the brood-chamber and mixing with the new wax, and thus soiling it enough to be perceptible, and we can not even grade it No. 1; but as there seems to be no grade below that, what shall we do with it? I believe some of our largest dealers say they have no use for only two grades. And so I might go on giving my experience in trying to

grade by rule; but after trying it a while I gave up in disgust. It seemed as if the bees had never been informed that these grading-rules had been adopted in Washington some years ago by a lot of very wise bee-masters, and so they have kept right on finishing off their surplus without any regard to them in more than twenty different ways, putting pollen into some of the whitest combs, leaving a cell uncapped here and there, or forgetting to attach the combs at their edges firmly enough to satisfy the rules, although strong enough to bear transportation to the ends of the earth. Worse than this, they have desecrated and tramped over their own work until it is unfit for any grade according to the rules.

I said I gave up trying to grade by rules adopted by our N. A. B. A., and so I did—not because it was impossible, perhaps, but wholly impracticable and unwise. Had I succeeded in getting one-fourth or one-half of my honey to correspond with "Fancy" of the rules laid down, I have no reason to believe I should have received a penny more for it than for it as graded, while I should have been quite sure to receive less for the remainder.

I asked one of the largest dealers in New England to make any suggestions or criticism upon my honey, or find all the fault with it he could. He wrote me it was entirely satisfactory, except that it was rather heavy weight. The season being good, the boxes were heavier than usual. I took 24 cases out of a pile of several tons, and shipped to Liverpool, and soon had an order from there for 240 cases just like those I sent, which sold in the open market there at the same price as very best grades of English honey, notwithstanding the English prejudice against foreign goods.

In looking it over I do not see how I could have graded my 1896 crop of honey to any better advantage than I did. And, again, I feel that had I tried literally to follow the rules laid down I should have missed it. It is undoubtedly desirable to have some general rules in grading for commercial purposes, or to facilitate the trade of honey in large lots. I do not see how half a dozen lines can describe the process of grading so as to do justice to both producer and purchaser. Much must depend on the good judgment of the one who grades, as well as in following the rules.

Brevity is said to be the soul of wit; but I doubt if brevity in rules for grading honey is any part of wisdom. According to the rules as they now stand, a speck of propolis on the outside of a comb, or even the section, would spoil it for "Fancy" or even No. 1, while a heavy base or septum of wax, or even several cells partly filled with pollen, might pass for "Fancy."

I take up a bee-journal and look at the quotations, and I am not surprised to find consider-

able variation in the price in the same market of a single grade of honey. In the *Bee-keepers' Review* for March, now before me, I notice that R. A. Burnett, of Chicago, one of the largest wholesale dealers in the country, quotes "Fancy" at 11 to 12 cts., while No. 1 white he quotes at 10—as much difference between different lots of "Fancy" as between "Fancy" and No. 1.

Batterson & Co., of Buffalo, in same issue of *Review*, quote "Fancy" 9 to 10 cts., and No. 1 white 8 to 9—quite as much difference in price in the same grade as between different grades. Middlebury, Vt., May 7.

[For some little time before the article above came to hand, we had been having some correspondence with a number of bee-keepers, asking for their private opinion in regard to the grading rules adopted by us and other publishers of bee-journals. Up until a year or so back there had been no grading-rules in force, and it finally occurred to me that the bee-journals might themselves adopt a set of rules without reference to any convention or organization, and I selected, for GLEANINGS therefore, those prepared by Dr. C. C. Miller, which I herewith give you at this time along with the Washington North American grading side by side.

## WASHINGTON.

FANCY.—All sections to be well filled; combs straight, of even thickness, and firmly attached to all four sides; both wood and comb unsoiled by travel-stain, or otherwise; all the cells sealed except the row of cells next the wood.

NO. 1.—All sections well filled, but combs uneven or crooked, detached at the bottom, or with but few cells unsealed; both wood and comb unsoiled by travel-stain or otherwise.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark. That is, there will be "fancy white," "No. 1 dark," etc.

## MILLER.

FANCY.—All combs straight, white, well filled, firmly fastened to wood on all four sides; all cells sealed; no pollen, propolis, nor travel stain.

No. 1.—Wood well scraped, or entirely free from propolis; one side of the section sealed with white cappings, free from pollen, and having all cells sealed except the line of cells next the wood; the other side white, or but slightly discolored, with not more than two cells of pollen, and not more than ten cells unsealed beside the line of cells touching the wood; the comb fastened to the wood on four sides.

No. 2.—Three-fourths of the total surface must be filled and sealed; wood well scraped of propolis.

No. 3.—Must weigh at least half as much as a full-weight section.

For the classes of honey I would suggest the terms already in use, sufficiently understood from the names alone, namely, LIGHT, AMBER, DARK, MIXED.

After I started to put these in force for GLEANINGS, Mr. Hutchinson, of the *Review*, wrote, asking why we should adopt a new set of rules when the Washington grading had been adopted by him for two years, without one word of dissatisfaction or complaint. This seemed like a clincher, and accordingly I threw Dr. Miller's grading overboard (and I guess I must have shut my eyes when I did it). I adopted the Washington grading, and immediately suggested the wisdom on the part of the publishers of the other journals to help us put the grading rules into force. Some of the brethren (not the editors) demurred, but (again I shut my eyes, I think) demurrers I would not accept any more, because I thought it was high time that we should try something, and not keep continually "talking," and doing nothing.

Well, two years have elapsed. The Washington grading has been tried and found wanting; referring to which, one intelligent bee-keeper, in a private letter, says:

"The first thing that strikes me is a feeling of wonder that a set of honest and intelligent men could agree to the Washington grading. I can see how intelligent rascals or honest ignoramuses might do so, but not men both intelligent and honest."

Now that I have my eyes wide open I do not know whether to call myself an "honest ignoramus" or one belonging to the other class. Whichever it is, I am in good company. Brother Crane himself was present in Washington when the grading rules were adopted, and so was Mr. Secor, Mr. Frank Benton, and a score of others; and later on was added to the list the editors of the various bee-journals.

Mr. Byron Walker at the very outset showed that the Washington rules were drawing things down too fine—that it was impossible to grade honey strictly according to them. To prove his assertion he actually advertised to pay \$1.00 a pound for "fancy" honey graded strictly according to the Washington grading. I was almost inclined to refuse his advertisement, for I hardly thought the man was in his right mind to offer such a price on honey. But you see he had his eyes open (though mine were shut) and knew what he was doing. It is needless to say that he failed to get a single pound of honey. I suspect that, if we had sat right down, as Mr. Crane did, and actually tried the rules in Washington, that city where wisdom sits supreme, we should have seen they were practically good for nothing.

I asked some of the brethren, with whom I had been having correspondence, to give us their ideas regarding the rules already in force, and to make such amendments as, in their judgment, would make them all right. The following letter from Byron Walker has been lying on my desk for some time, and will explain itself:

I find it quite difficult to make any amendments in a few words that would give my ideas of what the grading should be. Mr. Thompson's suggestions are mainly in the right direction; but I think it necessary, in order that such rules be of practical use, that more definite terms be used with reference to the matter of discolored and unsealed combs. In fact, I see no reason for materially altering the criticism in my article on this subject, published in the *American Bee Journal*, vol. 28, page 817. Certainly more than two grades are necessary to include the bulk of marketable comb honey; but the suggested fourth grade could be dispensed with. I would suggest that combs varying considerably in thickness, but which would otherwise find a place in the fancy grade, be assorted so that they will not vary in weight more than two or three ounces in any shipping-case. I have no doubt that too much stress has been placed upon sections being entirely free from propolis, in order to be ranked as fancy. The fact is, while reasonably neat sections are quite desirable, the suspicion of there being manufactured comb honey on the market is so prevalent, both among grocers and consumers, that at least a slight softening from propolis will, as a rule, help rather than detract from the sale of even the fancy grade.

Chicago, Ill.

B. WALKER.

The following is the draft of the grading-rules amended by him. By referring to the Washington rules above, the reader will see just where they differ. You will notice that he leaves out some things that are almost impossible of attainment in "Fancy," and makes No. 1 flexible enough to take in the great bulk of the best honey of the bee-keeper.

#### WALKER'S AMENDED WASHINGTON RULES.

FANCY.—All sections to be well filled, combs straight, of comparatively even thickness, and firmly attached to three sides, the comb unsoiled by travel-stain, or otherwise; all the cells sealed except the row of cells next the wood.

No. 1.—All sections well filled, but combs uneven or crooked, detached at the bottom, or with one-eighth part of comb surface considerably soiled or unsealed, or the entire surface slightly soiled. While a slight soiling of sections by propolis should not exclude them from the fancy grade, the sections must be reasonably neat in both grades.

Prior to the reception of Mr. Walker's letter and his rules of grading, I had received a draft of the rules from Mr. B. J. Thompson, of Waverly, Wis., which he had modified to read as follows:

#### THOMPSON'S GRADING RULES.

FANCY.—All sections to be well filled, combs straight, and firmly attached to all four sides, the comb unsoiled by travel-stain, or otherwise; all the cells sealed except the row of cells next the wood. The wood, if stained, to be thoroughly cleaned in every grade.

No. 1.—All sections well filled, but combs uneven or crooked, detached at the bottom, or with but few cells unsealed; comb may be soiled a little by travel-stain, propolis, or otherwise.

Dr. Miller, having seen both Mr. Thompson's and Mr. Walker's drafts, wrote as follows:

After carefully comparing the gradings, putting much faith in Walker's grading as an honest man of intelligence and much experience, and after considerable discussion with Emma, who doesn't entirely agree with me, here's what comes:

FANCY.—All sections to be well filled, combs straight, firmly attached to three sides, the comb unsoiled by travel-stain or otherwise; all the cells sealed except the row of cells next the wood, the outside surface of wood well scraped of propolis.

No. 1.—All sections well filled, but combs uneven or crooked; one-eighth part of comb surface soiled or unsealed, or the entire surface slightly soiled. Outside surface of wood well scraped of propolis.

Mr. Thompson leaves out of fancy "of even thickness," and Mr. Walker says, "of comparatively even thickness." I leave it out entirely. If you have "combs straight" there won't be much trouble about "even thickness," and "comparatively" is indefinite at best.

Both men omit "both wood and," which I think is all right; but by putting nothing in its place they jump to the other extreme, and you will see that allows a man to put in fancy honey all his sections without a knife ever touching one to scrape the propolis. So I add "outside surface of wood well scraped of propolis." Walker comes at it indirectly by saying, "reasonably neat in both grades."

In No. 1 I omit "detached at bottom." as that is not necessary, being already allowed in fancy by saying, "attached to three sides." I think it might be better to word No. 1 thus:

"No. 1.—The same as fancy, only the combs may be uneven or crooked, one-eighth part of comb surface soiled or unsealed, or the entire surface slightly soiled."

The other way leaves it that the comb need be attached only at the top, which would hardly do for shipping. Please understand that this last No. 1 stops at the paragraph quoted.

I've tried without prejudice to say what change would allow such men as Walker and Muth to use the grading; but no amount of tinkering will make it right to call the bulk of the crop fancy and the rest No. 1. It isn't honest, and that's all there is about it.

Emma objects, and with no little reason, to "combs unsoiled by travel-stain or otherwise." If it were *really* fancy it would be all right. But as fancy is really the bulk of the crop, and No. 1 the seconds, it will be impossible to get more than half the sections to come up to the requirement in that particular. It isn't the general thing to take off a super of sections in which every section is snow-white. Some of the comb surfaces are *slightly* discolored before three-fourths of the sections are sealed. A very slight discoloration does not and ought not to rule them out. But perhaps that can stand, as in practice it can not be strictly adhered to.

I don't like any of it, but I think I've tried to follow out the spirit of what you want.

C. C. MILLER.

Marengo, Ill.

[Now, I am not going to say at this time which set of rules is best; but one thing is certain: Before we adopt another set for GLEANINGS, we shall need to know that the set we *do* fix upon shall receive the approval of the brethren who have so kindly shown up the mistakes of the accepted Washington grading. I am not sure that any thing we can patch up of an old thing will be as serviceable as something that has been made by one person and is brand-new. What think you of the first set of rules, or the one originally proposed by Dr. Miller? As for myself I am at present inclined to believe that the Washington grading as amended by Walker or Miller would be as good as any. They would have the advantage that they would be the same as the ones with which we have been familiar, without their objectionable features. Of the two, the Miller-Washington is the briefer. Let's have brief expressions on postals from a large number. The revised rules, to be of any use for this season, ought to be ready for our next issue.—Ed.]

## RETAILING FROM SQUARE CANS.

IS GLUCOSE A LEGITIMATE ARTICLE OF COMMERCE?

By R. McKnight.

"Selling Extracted Honey;" "Valuable Secrets." Such is the caption over an article published in GLEANINGS over the signature of Mr. Chalon Fowls, and copied into the *American Bee Journal*. Doubtless Mr. Fowls is satisfied he has discovered the secret of selling extracted honey. Let us look up for a moment what he considers these *secrets* to be. It is to be "of the finest flavor, and in color the whitest." These are certainly requisite in the rapid sale of honey. It is to be liquid in form—this is also desirable. Then it is to be put up in flint glass jars holding a pint each, and in third-pint jelly-glasses. This is not a good way to sell *much* honey *rapidly*. At the present price of honey it is folly to put it up in any kind of package that compels one to sell it to the trade at what Mr. Fowls says he charges for it—23 cents a pint. True, the Mason jar is worth its value to the purchaser; but as a rule people won't buy honey or any other article of food because of the character or quality of the vessel that contains it. It is very necessary that this should be neat, clean, and attractive. I think bee-keepers may settle down to the conviction that, all things considered, tin vessels are the best and most economical receptacles for extracted honey when put on the market. These should be of such size as to meet the requirements of the purchaser. Few people care to buy more than 20 pounds of honey at a time, and five people will buy five pounds for one who will buy twenty pounds. For the general retail trade a 20-pound package is the largest needed. More extracted honey can be sold when put up in from five to ten pound tins than in any other form.

For some years past I have found a seven-pound square tin package the most popular with both the merchant and his customer. A few years ago they retailed readily for a dollar each. I never could understand why the orthodox 60-pound tin is so generally used to put up honey in. It certainly is not a suitable package for the retail trade.

A dozen years ago or so I was in a neighboring town. While there I called upon a grocer who happened to receive an order for two pounds of honey while I was present. He dragged a 60-pound tin of candied honey from under the counter, and through a four or five inch opening in the top he proceeded to extract the 2 lbs. of extracted honey asked for. Before he was through with the job his knuckles were daubed with honey to an extent calculated to make him forswear handling such stuff in future. I then and there made up my mind I would never send such a package to a grocer, and I

never have. The best plan is to put it up in quantities of from 5 to 10 lbs. I am sure the lady who ordered the 2 lbs. I have referred to would have bought a 5-lb. package if the merchant had had it.

When liquefying honey, Mr. Fowls tells us he never allows the water surrounding the vessel containing it to boil. Can he assign any good reason for such caution? It is not wise to allow honey to boil; but honey can not be made to boil by surrounding it, or keeping it surrounded with *boiling* water. It requires a good deal higher temperature than 212° to cause honey to boil.

I should like to enter my protest against the frequency with which bee-keepers (Mr. Fowls included) refer to glucose as "vile stuff." Glucose is not vile stuff. It is a legitimate article of commerce, and its production and sale are as honorable as the production and sale of any other article of commerce when sold for what it is. We are apt to boast of the healthfulness of honey. The sugar of glucose is chemically identical with the saccharine matter of honey. It, too, ought to be healthful.

R. MCKNIGHT.

Owen Sound, Ont., Canada.

[Square cans are used very largely by producers for putting up honey in bulk, in the same way that barrels are used; but, unfortunately, some climates will not admit of the use of these latter, owing to the shrinkage of the staves. In cases where the square cans are used for retailing from, a honey-gate should be used, costing only 15 cts.; and the producer who does not supply his grocer with such a gate is very shortsighted. When a grocer daubs his knuckles as you describe, just because he has not a proper appliance, both he and his customer are liable to become disgusted with the whole business. Perhaps in many instances it would be wise to let the grocer have only 2, 5, and 10 lb. cans of honey, and perhaps he would daub his knuckles any way, for some men are always daubing.]

I believe nearly all our readers will take exceptions to your last paragraph; at least, from a bee-keepers' standpoint it can hardly be regarded as orthodox. In the first place, I can not agree with you that glucose is not "vile stuff." The article that is ordinarily used for purposes of adulteration is hardly fit to put into the stomach of a pig, let alone that of a human being. A few years ago, in testing samples of glucosed honey I made myself sick, and it took me nearly a week to get over the effects of sampling the "vile stuff." It was nauseating, to say the least; and even now it brings to my mind the horribly nasty taste that clung to me for days after tasting it. I grant that there is a glucose of very fine quality that does not taste bad; but we seldom find such used as an adulterant, because the cheaper grade when put into honey looks just as well, and fools the uninitiated just as easily as the better grade.

You say, further, that glucose is a "legitimate article of commerce;" I don't know how you make that out. If glucose were not used for adulterating syrups and honeys it is doubtful if there would be a glucose-factory on the continent. It is true, glucose is sold in bulk for what it is; but to whom, pray, does it go? To the mixers, who will put it into syrups and

honey, cover up its identity, and who will name it either "pure maple syrup," from Vermont or Ohio, or "pure farm honey," etc. If glucose is to be ranked as an honest product in the sense that honey, flour, and meat are, why do we never see it advertised in the general run of papers? In common market quotations it is never mentioned—is not this fact alone enough to convince any one that this stuff goes directly from the factories into the vats of those who mix it with the product of honest labor to rob the farmer to just the same extent they enrich themselves? Did you ever hear a grocer recommend an article because it contained glucose? Does he not always carefully conceal that fact if he can? It signifies nothing to say that it is a legitimate article of commerce. So are whisky and opium, but surely in this case the altar does not sanctify the gift.

I have been told that glucose has been used to preserve dead bodies; that, when immersed in the "vile stuff," said bodies will keep indefinitely. There are other "vile stuffs," such as alcohol, etc., that have the same property. But alcohol has a few legitimate uses; but glucose, beyond the possible one mentioned, is used first, last, and all the time for cheating and defrauding, unless when it is used for making beer or spirituous liquors.

I will grant that the sugar of glucose is chemically identical with the saccharine matter of honey. Chemically the diamonds in the British crown are identical in substance with charcoal.—Ed.]

## BEE BUZZINGS.

### EXTRACTING.

By E. H. Schaeffle.

I prefer to take off honey very early in the morning. Over night the honey has all been evaporated, and there is then no thin honey requiring after-evaporation, or souring for the want of it; the bees are not flying, and so do not become excited. During the day the combs are all extracted, and returned late in the evening, thus preventing robbing as the combs are all cleaned up over night, and do not attract the robbers on the following day. As a rule I leave an unfinished comb in the super for the bees to store in during the day's absence of the other combs.

### EXTRACTOR.

I use a Cowan, and should like it still better if there were a groove in the bottom, where the gate enters the can, so that all of the honey would drain out with the can standing level. Frequently a black mixture of iron and honey oozes out of the bottom bearing, and is a nuisance to scoop out of the honey. This, I think, could be remedied by reversing the position of the bottom pin and bearing, and using ball bearings placed above the honey. As the extractor is now built, if five gallons is allowed to accumulate, the honey works into and the iron out of the bearing, and trouble follows. It is not possible to oil the lower bearing; but with ball bearings this would not be required. The machine would run far easier, and, with a more rapid gear, make extracting less laborious.

With the present slow gear the operator must, if the honey is as heavy as that which I am extracting, run at his utmost speed. I do not find it necessary to evaporate my honey after extracting, as I allow the bees to do that for me. While I may not secure quite as large a crop in consequence, I am satisfied it is enough better to offset the loss. I find a light block and tackle a great convenience in extracting. With it I can pick up the extractor, when full, place it on a table, strain out the honey, and drop the extractor back on to the floor, without any special effort.

### FEEDING.

In a recent number of GLEANINGS a subscriber advised the use of honey only in feeding. Recently there has been a pure-food crusade in San Francisco. One of the city's leading grocers was arrested, fined, and greatly injured in trade by an analysis showing the honey he sold to contain a small per cent of cane sugar. Now, this grocer, to be sure of the purity of the honey he sold, bought direct from an apiary whose owner guaranteed the purity of the honey under a penalty of \$150; but the chemist said "cane sugar," and the grocer suffered; the bee-keeper lost a good customer (yours truly got him). I feed only pure honey, and fear no honest analysis.

It is evident that the bee-keeper had fed sugar syrup in the fall or spring feeding, and the bees, when crowded, had extracted a portion of it to make room for the queen, and carried it up into the super, where it was thrown out with the other honey, and while the per cent must have been exceedingly small, the chemist found it in his test, and the fines and losses followed.

### HONEY YIELD.

February, March, and a portion of April was an almost continuous shower, with an unusual amount of bloom in April, and one of the best spring flows that the State has ever produced. Since then it has turned hot and dry, with the result that reports from all parts of the State agree that the flowers are withered and gone, and the remainder of the season will be very light, and in some sections feeding will be required to carry the bees over to the fall flow. This in most sections is barely sufficient to furnish the bees with a good supply of winter stores. With me it varies. Some seasons my fall flow is better than that of the spring; as a rule, however, it is only fair.

### PRICES.

The dealers write me that I must be mistaken about the yield, as the bee-men, jobbers, and country storekeepers are all trying to force their honey on to them in large amounts. This, I think, is the result of the past short seasons. The bee-keeper is hard up, and hastens to realize, fearing a drop in price, with the result that the price is forced down, notwithstanding the

crop is small; and now that glucose is barred out, the consumption is double that of former seasons.

#### TAKING OFF SECTIONS.

Smoke excites the bees, and causes them to uncap the honey, as does any rough handling. I find the following method works nicely: Early in the morning pry up the super containing the sections, doing it as gently as possible; move along to the next hive; and when you have three or four loose, go back to the first hive, where the bees have quieted down, and quickly raise the comb super; slip on the bee-escape board, and replace the super. The bees are slow to move early in the morning; and if care is taken in prying up the super, giving them time to quiet down, and skill used in slipping on the escape, the bees will not become excited, no caps will be cut, and the bees will work out as nicely as though they had been driven wild with smoke, and remain gentle.

#### PRIMING SECTIONS.

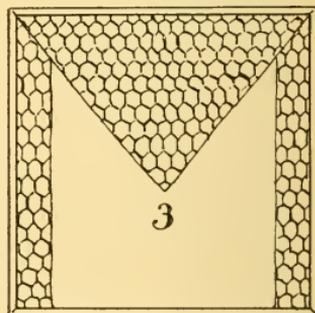

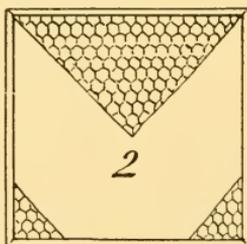

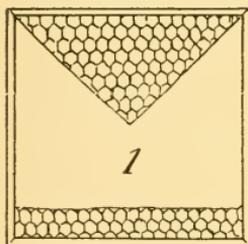

By reference to old articles of mine I think you will find that I used both a bottom and lower corner starter. With me the bottom

are unnecessarily heavy. A steel fire-box and a perforated cover are all that is required, which, with a tin bellows, would decrease the weight a half.

Murphy's, Cal.

[We formerly made extractors with the groove in the bottom where the gate enters the can. After we changed to our present plan we found that it is not only cheaper, but bee-keepers appreciate it. The directions that go with the machine are to screw it down so the honey-gate will be directly over the bung-hole of the barrel or other receptacle. It is not designed to let the honey accumulate in the can. When that is desired we make deeper cans and raise the bearing up a few inches. Of course, we have to charge extra for such change. The great difficulty with the old grooved bottom was in cleaning. With the present plain bottom slanting toward the honey-gate, every portion of it is "gettable."

The Crane smoker will not go out, usually, if you get it well going in the first place, and use the right kind of fuel. The Corneil, however, seems to have the preference nowadays; and while it does not give as strong a blast it will never go out as long as there is fuel to burn and of the right sort. We prefer the stringy sawdust that comes from making the hand-holes in hives. Planer-shavings answer nearly

starter had a bad habit of curling over. The corner starter seemed to work for a time, but in the end I found there were more of them gnawed out by the bees than there were left standing, so I left both bottom and corner starters out. At present I use a strip down both sides, and a triangular piece in the center.

#### BEE-SMOKER.

I found my Crane smoker had a bad habit of being out just when I needed it badly. To remedy this I punched a  $\frac{3}{4}$ -inch hole in the front, just above the floor, and covered this with a piece of finely punctured tin. Now when I get the smoker going it keeps a going. For convenience in handling I have a strap nailed across the top, with sufficient room under it to slip the hand in. I find the strap comes in very nicely in going to and fro in the apiary after combs when extracting, as with it I can hang it on to the handle of the barrow, and it always keeps right side up. The body of the bellows should be of tin to make it lighter. Smokers

as well. Small sticks of stovewood we have used some, but very much prefer the loose material, as it gives a denser smoke.—Ed.]

#### THE NEW DRAWN FOUNDATION IN ENGLAND.

APIS DORSATA, BY ONE WHO HAS SEEN THEM IN THEIR NATIVE HOME.

By F. W. L. Sladen.

Mr. Root:—I am in receipt of your letters of May 1st and 17th. The sample package of foundation, containing a small piece of the new drawn comb, also came safely to hand. With regard to the drawn comb, I congratulate you on your marvelous achievement, which must ever stand out in bee-history as a record of advance. I think the new drawn comb will prove particularly useful in the rapid harvesting of honey, and also for the prevention of "pop-holes," which are frequently nibbled

through foundation, next the wood, in frames and sections. The use of the new drawn foundation will make the adulteration of comb honey hardly any easier than in the past. It is always possible for unscrupulous persons to get the bees to fill their combs with syrup, whether drawn comb, ordinary foundation, or no starter at all be given.

I am pleased to see in GLEANINGS that you are taking practical steps to sift the *Apis dorsata* mystery, and wish you every success. As, perhaps, you know, I took a voyage to India last winter for health, and spent a month there taking specimens and getting information about the various types of bees to be found in the country, especially of the genus *Apis*. I set out with the firm belief that any of the Indian honey-bees, to be of any value to us, in our climate at least, should come from the mountains and not from the plains; and after my month's tour I felt more than ever convinced of this. Now, *A. dorsata* is essentially a plain bee, though I did meet with a deserted comb at 2000 ft. elevation on the southern slopes of the Himalayas; and I am almost afraid that you will make nothing of it—at least in honey-producing. If properly managed in the Southern States it might give wax, but I doubt if you could make Weed foundation of quality as at present with *dorsata* wax. I met with *A. dorsata* fairly commonly in a ramble taken at Siligari at the foot of the Himalayas. The sky was cloudless, the air still, and the thermometer stood at 75° in the shade (this in January), but *A. dorsata* did not see fit to appear for more than three hours in the day; viz., from 10 A.M. to 1 P.M.

My heart sank at first sight of a *dorsata* worker on the wing. With its heavy, dusky wings it emits a low-pitched hum, indicating the slowness of vibration. It goes from flower to flower in a lazy, unsystematic way, frequently pausing for rest on a prominent leaf, forcibly calling to mind Cheshire's interesting illustrations of the comparative feebleness of large creatures. To say that *A. dorsata* bears the same similarity in behavior and appearance to an ordinary honey-bee that a hornet does to a wasp would give a very good idea to an observant Englishman of the "nature of the beast."

I made a dissection of two of *A. dorsata* on my return, and the following figures may be of interest to you. I have had to suspend all this kind of work for the present until the winter.

|                                          | L'gh of body. | Approx. l'gh of tongues (ligula). |
|------------------------------------------|---------------|-----------------------------------|
| <i>A. dorsata</i> (from Siligari)        | 15 m. m.      | 4 m. m.                           |
| <i>A. mellifica</i> (England)            | 12.5 m. m.    | 3.6 m. m.                         |
| <i>A. florea</i> (Calcutta)              | 7.8 m. m.     | 1 m. m.                           |
| <i>Bombus hortorum</i> (England), worker | 15 m. m.      | 9 m. m.                           |

I brought a case of specimens of wild bees back, many of them of exceedingly interesting structure, which I have not time to enter into

here. I have a large collection of wild bees from many parts of the world. If you know of any one in the Northern States who takes an interest in these things would it be too much to ask you, when communicating with him, to give him my name and address, as I should be pleased to make exchanges? I have a correspondent in New Mexico, and several in Canada, but none at present in the Northern States.

Ripple Court, England, June 8.

[This is very interesting and valuable, especially the comparative measurements of *Apis dorsata* and other bees. It would appear from the foregoing that their tongues are but little longer than those of the common bees, while the tongue of the bumble-bee is more than twice as long as that of the so-called giant bees. The claim has been made that these bees would be especially valuable in this country, for the reason that they could get honey from red clover and other flora having deep flowerets; that they would be able to do for us in the way of fertilization what the bumble-bee does, and more. If the comparative measurements of bees' tongues are correct the claim is rather flimsy. We should be glad to hear from Mr. Sladin further on the subject.]

After the article above was in type, the following, from our old friend and correspondent, A. Bunker, the one who has written in years gone by, on the subject of *Apis dorsata*, and who has been living right in their native climate for a good many years, is especially opportune and valuable:

*My dear Friend and Bro. Root:*—Once more, after four years' absence on the Burman field of missions, I am permitted to greet my family. I find a large place empty by the death of my boy while away. God has, however, given me many spiritual children to make me glad. We baptized 457 converts during the last two years; added over 1600 to the attendance at our Sunday-school, and organized five churches during the last year. Praise the Holy Spirit, who gives the increase.

I see considerable speculation about *Apis dorsata* in your journal. Having studied that bee in its native habitat I am afraid it can not be domesticated more than it has been. It is a migratory bee. During the dry season it travels south, and takes up its home, usually in the same place, from year to year, among great flowering trees. As the rains come on, it leaves for the North, and I have found its home in high mountainous tracts, where the natives plant stakes in the side of a hill horizontally, digging a ditch under them, and leaning a few boughs against the stake for protection.

The amount of honey gathered by this bee always seemed to me to be small when compared with that gathered by other bees, and taking into consideration the size and numbers of the bees. It is possible their habits can be changed, but I doubt it. If any one wants to study them for himself tell such a person to go to Tongoo, Burma; get a camping-out kit, and go back into the forest 20 miles to the east of

that city, in December, and he will find many swarms for study; or, if he will apply to the missionaries at Toungoo he will get guides who will take him to the bees, and secure swarms for him if he wishes them to do so.

Bro. Root, I prize your Home Papers very highly. They are practical; and religion, if not practical, i.e., reduced to practice, is not worth much. Long live GLEANINGS. Its editor, A. I. Root, will live forever, because Jesus lives. A. BUNKER.

54 Willow St., Providence, R. I., June 24.

[I believe there is no one in the world who is more competent to speak on the subject of the general characteristics and habits of *Apis dorsata* than is Mr. Bunker. Both he and Mr. Sladen, as well as others, express strong doubt that these bees can ever be domesticated. It is claimed they could be, and are kept in common hives in this country. It looks as if this claim were made in the interest of a fat government job for some one; and if so, bee-keepers all over the land should enter a most decided protest against the use of public funds for this purpose. The missionaries already in or about to be in the field, Mr. A. Bunker and Mr. W. E. Rambo, can conduct experiments, and, if necessary, ship the bees to this country, at a merely nominal cost—a cost so low, in fact, that the expense can be borne easily by private enterprise.]

We had lost sight of Mr. Bunker; and had I known where I could have written him I would have asked his opinion long ere this. Now that we have got hold of him again, we shall hope for his advice and co-operation, in connection with the proposed efforts on the part of Mr. Rambo, in securing these bees.

I am sure our readers will deeply sympathize with Mr. Bunker in the loss of his son. At the same time, we shall also rejoice over the grand and noble work that he has done through Christ. The self-sacrificing work of such a missionary leaving home, family, and friends, to carry the gospel to heathen lands, to express it mildly, commands our admiration. Could any work be more noble and unselfish?—ED.]

THE MONGOOSE IN JAMAICA; WOULD THE IMPORTATION OF *APIS DORSATA* BRING DIRE RESULTS?

I send you a clipping from the *American Field*, in reference to the mongoose in Jamaica. I fear *Apis dorsata* might prove to be a similar curse to bee-keepers in this country. I for one am satisfied with Italians.

The introduction of the mongoose into Jamaica marks one of the standard instances of unexpected results following upon an attempt to artificialize the process of natural selection, and takes rank as a warning with the plague of rabbits and thistles in Australia, says the Academy. The mongoose was introduced from India, in 1872, in order to abate the pest of rats which infested the sugar-canes; and after performing this salutary duty it increased and multiplied to such an extent that not only the rats and mice but most of the living species of the island were threatened with extinction. Poultry suffered first; but the depredations extended to young pigs, kids, lambs, newly dropped calves, puppies, and kittens. Game of all kinds was attacked, both living and in the egg. The marauder ate even fish, and made such a specialty of snakes, ground-lizards, frogs, turtles, and land crabs, that many kinds of these entirely disappeared. Finally the mongoose developed a ravenous desire for bananas, pineapples, young corn, avocado pears,

cocoas, yams, and the sugar-canes, which it had been called in to protect, winding up its tastes with an appetite for salt meat. The result was a wholesale disappearance of species. A few birds, like the ground-dove, had the sense to shift their breeding-places to the tops of the prickly cacti, where they were safe; but other animals, and the reptiles in particular, suffered so severely that many kinds were believed for years to be extinct. As a consequence there arose yet another plague. Insects like the ticks and "jiggers" (or chiggers), which used to be kept down by the snakes, increased so overpoweringly that men and cattle were grievously infested. One could not walk without being covered with them. The victory over the island remained with the tick and the mongoose, until, within the past year or two, a fresh stage set in. The mongoose suddenly began to be less plentiful, and it was found that he had fallen victim to the tick. The results of the diminution are shown in a gradual reappearance of other beasts, birds, and reptiles. Among the snakes there is a very marked increase; and even the ground-lizard, supposed to be quite extinct, has become common again. The balance of life has begun to reassert itself, and naturalists will watch with curiosity for a complete reinstatement of the previous fauna. The renewed depredations of rats are hailed as an advent of salvation, and, odd as it may sound, the increase in numbers of the crocodile is taken as a happy omen. The Jamaicans are not likely to make further experiments in this interesting domain of natural history, but will adhere in future to such present evils as they have. For them, at any rate, it has been no "imaginary mongoose."

Chambers, Ala., May 24.

J. M. CUTTS.

CLIPPING QUEENS' WINGS.

*Question.*—Do you believe in clipping queens' wings? If you do, will you tell us in GLEANINGS all about it—how you clip, why you clip, etc.? I am told by a neighbor that it is too much bother to hunt up the queen, and that it is a delicate job to clip her wings when she is found, and that there is more harm than good in doing it, anyway. Is this neighbor right?

*Answer.*—While there may be a grain of truth in what your neighbor tells you, yet when we come to "count noses" the greatest weight of evidence from the "dollar and cent" apiarists of our country is in favor of clipping queens' wings; and as I believe in so doing I will give some of the reasons for such a belief.

By having the wings of all queens clipped you have the bees perfectly under your control, and can handle them as you wish, separating them with pleasure when two or more swarms cluster together, and hive them without climbing trees, etc., on the returning plan, when they come singly, they virtually hive themselves. In using this plan all you have to do when the swarm issues is to step to the entrance of the hive with a little wire-cloth cage into which the queen is let run, when the cage is stopped and laid in some convenient place. The old hive is now moved to a new stand, and a hive fitted for a new colony set in its place. In from a few minutes to half an

hour the bees miss their queen and come back to her or their supposed old home, which was there when they went out. On changing hives the queen was placed near the entrance, so that, as soon as the bees returned, they might find her, and not scatter about the apiary to other hives, as they sometimes will if they do not have ready access to their queen. As they return they will commence to run into the new hive with fanning wings, when the queen is liberated and goes in with them. I have followed this plan for more than a quarter of a century, and know it to be a good one, as good yields of honey will testify—no climbing of trees, cutting off limbs, or lugging a cumbersome basket or swarming-box about. It is straightforward—remove the old hive to a new stand, put the new hive in its place, and the returning swarms hive themselves with little or no trouble, save the releasing of the queen.

Again, I clip the larger part of the queen's wing off, so that she may be the more readily found. In making nuclei, changing frames of brood and bees, extracting, making swarms artificially, if we wish, etc., if you find the queen you can always know that she is just where she belongs, and not in some place where she ought not to be. By having her wings cut short you can see her golden abdomen as soon as your eyes strike the side of the comb she is on.

Once more: There is no loss of bees by going to the woods when the queen's wings are clipped. That bees do go to the woods, all can assure themselves by reading the reports given in our various bee-papers, if they do not know of the same by actual experience. The bees may try for the woods, and they often do; but as soon as they miss their queen, back they come, for they realize that swarming is of no purpose to them unless they have a queen with them to repopulate their home after they die of old age. Many a time have I had swarms start for the woods and be gone from sight and hearing for some little time; but as soon as they missed their mother, back they would come, setting up a joyful hum when they found her.

But how to find the queen, and how clip her wing, is something we must know about if we practice this method. The time of the year in which we undertake this matter has much to do with the pleasure of this work. If we wait till just as swarming is upon us, and attempt to hunt up a queen in a hive that is overflowing with bees, and especially one which will probably swarm in a day or two, when the queen has ceased her laying pretty much, so that a burden of eggs need not hinder her from flying with the swarm, and thus cause her to become no larger than she was when unfertile, we shall well speak of the matter as "a bother;" for to find a queen under such circumstances often baffles the most experienced apiarist. But if

we do this work in fruit-bloom, when there are comparatively few bees for the brood they are covering, and the queen very large from her prolific egg-laying, using the time from 9 A. M. to 3 P. M. to look for queens, it will be a rare thing that one will evade the efforts of even the novice. Take along an empty hive and set it where you can easily place the combs, as handled, into it, when you will proceed to open the hive, using just as little smoke as possible—only just enough (or none at all) so that the bees are kept from stinging. Do the work carefully, so as not to jar the hive or frighten the bees. Carefully lift the first frame; and as it comes from the hive, glance at it to see if there is brood in it, for it is useless to look on combs having no brood in them if you have not stampeded the queen by careless operations.

As soon as you find brood, look closely for the queen, glancing first down the side of the comb next to you in the hive, and then on the opposite side of the one you hold in your hand, holding the comb a little obliquely as you look, for the side of the queen gives a better view than straight on her back. As the combs are taken from their hive, set them in the one you brought, so that, should you not find her the first time over, you will be likely to do so in setting them back. In this way, after a little practice, you will have little or no trouble in finding any queen, even should it be a black or German queen. Having found her I take her by the wings with the thumb and forefinger of my left hand, when, with my right, I place the sharp blade of my jack-knife on the part of the wings I hold in my left, lowering both hands to within an inch or so of the tops of the frames, when I draw the blade just a little, thus severing the wings, when the queen runs down into the hive the same as if nothing had happened. There is no danger of cutting fingers if you stop drawing the knife as soon as the queen falls. Some use scissors; but after clipping off a leg or two with them I took to the plan here given.

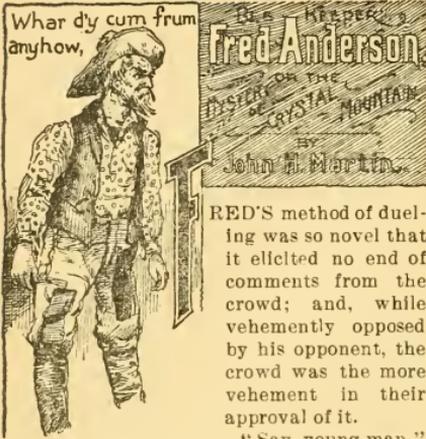

---

*J. R. W., Ill.*—Drones from pure Italian queens vary all the way from black to quite yellow, while the bees should be uniformly marked, having three distinct yellow bands. The fact that drones from a yellow queen do not show any bands whatever is no evidence that the queen is not pure. It is also true that queens vary just as much as the drones in color. See paragraph on this subject on page 29 of our catalog.

---

#### CONVENTION NOTICE.

The Texas Bee-keepers' Association will meet at Cameron, July 16, 17. All parties will purchase one-way ticket, paying full fare, take receipt at time ticket is sold, and these receipts, after having been signed by the secretary at Cameron, and stamped by agent, will authorize return tickets at one-third fare, provided there are fifty certificates presented.

RED'S method of dueling was so novel that it elicited no end of comments from the crowd; and, while vehemently opposed by his opponent, the crowd was the more vehement in their approval of it.

"Say, young man,"

said Slim Jim, "whar d'y come from, anyway?"

"I came from Maine," replied Fred.

"Jest as I mustrusted," said Jim; "fur nobody but an infernal Yankee'd ever think of sech a way of fitin' as that. My way is pistils, and it's pistils or nothing."

"I don't see that there is any difference as to how we fight, if it is only with deadly weapons," said Fred; "and I'll guarantee that the bees are as dead shots as any pistol you can produce."

"Yes," said Jim, "they may be deadly to me, but how's it to you? You mout be one of them fellers that bees won't sting."

"Well, then," said Fred, "I would have about the same advantage that you would with a gun. You are a dead shot, and I am not. I had a right to choose my weapon, and will fight with no other; am I right, gentlemen?" said Fred, turning to the crowd.

"Right! right!" assented the crowd.

Fred knew that, in drumming bees from a hive, they would fill themselves with honey, and be comparatively harmless, and could be thrown promiscuously into a crowd, and no stings result. But to those ignorant of the traits of the bee, the idea was full of terror; and Slim Jim's view of it was of the nature of a lingering death.

Fred was thoroughly opposed to dueling in every form; and in making his proposition he sought to make as much of a burlesque of it as possible, and was happy over his success; for after much talk, Slim Jim, after many imprecations against the "onusual ways of the infernal Yankees," made an ignominious withdrawal.

With Slim Jim out of the way, young Armstrong directed his attention to Dr. Hayden. The doctor told the story of the valley, his finding of it through the Indians, etc.; and when he had concluded, he said, "Now, if you doubt my word, here are my companions. Ask them."

Sam Johnson, in giving his experience in the valley, dwelt more upon what Dr. Hayden had done for him morally than he did upon a description of the valley, and concluded by saying, "Dr. Hayden am elevated me from de mire ob de dirty slough to de beautiful heablenly gardens; and though de beautiful valley am gone, de heablenly gardens remain in my soul, glory halleluia!"

Fred interested the crowd with a description of his first acquaintance with the doctor, and of his wonderful success with bees in the valley.

"Well, now, by snumm," said one of the crowd; "that explains a mystery. I've hunted bees all around Crystal Mountain, and the lines always led me right into them: glass knives. I calculated there was a big cave in there somewhere; but instead there was a whole valley, and who'd a thought it?"

Gimp Dawson gave some of his experiences with Sam Johnson, and said:

"When I was fust pitched inter the valley I hated that ar'nigger," pointing to Sam; "but afore I came out I come to conclude that, though he's black, thar are some white streaks in his heart. D'y'e see that ar'scar on my hand, and that on my shin" (pulling up his trousers)? "then thar is another on my hip—got cut on them glass knives. Wall, Sam done 'em up like a horsepital man, and on the hull we had a happy time, as Sam says, in de heablenly valley."

When Alfaretta told her story there was a visible effect upon the crowd. Many had heard of and a few had seen the "mad beauty" of the Sacramento; and now to have her in their midst, sane, and talking to them so pleasantly, was too much for them, and they broke, from murmurs from one to another, into a hearty cheer, and the cheer was as pointed for Dr. Hayden as for Alfaretta.

"Well, Dr. Hayden," said Pete Armstrong, "we had an impression that you were an evil genius, and an all-round bad man. Now, there is such a man and a murderer somewhere around that mountain. My father was shot in cold blood; that Dutchman Kishinka was also killed, and no telling how many men have been driven from the vicinity by burning of cabins or killing of stock."

"But why should I do such things," said the doctor, "while living peacefully inside the valley? No one was injuring me, and I am not a vicious man, as you have now learned. As to who has committed these crimes, I have nothing to say; but if you look sharp you may now find some one outside the valley who is interested in running people off a certain tract of land."

There was considerable quiet thought over the matter, and finally Pete Armstrong said, half to himself, "If I only knew!—but, wait; there is an Irishman squatting on a parcel of land on

the west end. We will see what becomes of him."

It was well into the evening before the conference ended; and that which started out with a prospect for a duel ended in a general peaceful hand-shake, and our party of homeless valley exiles were cared for in the combined grocery store, hotel, and saloon.

Late in the evening parties came in from Ukiah, and brought news of a startling nature about the earthquake. The State Capitol building at Sacramento had been demolished, and at Napa and Winters there had been a general wreckage of buildings and loss of life.

his early life and schooldays with Clarence Bull; "and now," said he, "it seems strange to know of him as Buell."

"But, doctor," said Alfaretta, "do you not think Buell much the prettier name? and only one little letter makes the change."

"Oh, yes!" replied the doctor; "it does sound pretty, but not so strong. Bull has an aggressive sound; and when you change it to Buell you sort o' knock the horns off, and make a muley of it; but, I beg your pardon for my blunt speech," said the doctor, as he observed a trace of a pout on the fair lips. "I will try to conform to the new order of names. It is

"A VERITABLE CONCERT WAS ENJOYED."

"Of course," said the doctor, "these are but rumors, and the damage can scarcely be expected to be as extensive as reported."

The next morning the party proceeded leisurely on their journey, and followed the old trail over the mountains toward the Sacramento River.

It was a constant cause of wonder to Alfaretta as to how she could have traversed those regions alone and in the night.

"Why," said she, "I should be afraid to travel this road alone in the daytime; but pony Jack, you say, was my guide and guardian. Dear Jack!" said she, patting the pony on the neck.

During the forenoon, as they rode along, the doctor conversed with Alfaretta much about

very handy to address you as M'ss Buell; but should I see my old friend I fear I should say Bull to him unawares."

"Well, doctor," said Alfaretta, with a smile, "my papa is good-natured, and you shall have that privilege. I anticipate the great pleasure it will afford him to meet you."

After the noonday lunch the doctor relapsed into silence, and rode some distance in the rear. Fred never enjoyed himself better than during that afternoon ride. Their pace was not rapid, for the ponies packed with the camp material could travel no faster than a walk. The homeward journey was a happy one for Alfaretta, and as much so for Fred, for he felt as though he had been in some degree instrumental in restoring his fair companion to health again,

and he knew there would now be joy in the Buell home where there had been sadness before. Their exuberance of spirits found expression in snatches of song; and around the campfire that night a veritable concert was enjoyed, Sam contributing an important element to it with his plantation songs.

The next day, in his conversation with Alfaretta, the doctor dwelt much upon filial love, and said:

"Alfaretta, I suppose that, after your recovery now, you feel the same love for your parents as before."

"Love them!" said Alfaretta. "Ah, doctor! It seems that I should love them more and more. Dear mamma and papa, always so tender, so kind, and the agony they must have endured these five long years!" and she brushed away a tear.

Again the doctor rode a long time in the rear.

He called Sam to his side, and their conversation was earnest and long. That evening the doctor was quite jovial, furnishing his quota of entertainment with reminiscences of his South American travels.

When Alfaretta retired to the little tent and cot provided for her, the doctor took her by the hand and bade her good-night.

For a long time Dr. Hayden sat gazing into the campfire. Fred addressed him a couple of times, but he seemed as abstracted as when Alfaretta first entered the valley. Fred, realizing his mood, rolled himself in his blanket and was soon sound asleep.

It was past midnight when Fred was aroused by a gentle shake. Upon opening his eyes Sam Johnson was kneeling beside him. In an undertone he said, "Fred, de doctor wants to see you jess beyond de sycamore-trees yonder. I guess he have suffin' to say to you."

Look out for irresponsible or new commission houses. They will offer big inducements and talk big about their ratings. They are still abroad in the land, and are waiting to rope you in if they can.

It is reported that the glucose-factories have formed a trust aggregating two millions of dollars. We bee-keepers hope this trust will put the price of the stuff up so high that it will not pay to use it in honey. Sometimes a trust is a good thing. Perhaps this will be an example.

THE convention of bee-keepers which is to be held in Buffalo, Aug. 24-26, will be a big one, from present prospects. The unusually heavy flow from clover throughout the country, and the very low rates of travel (one cent a mile) are two of the elements that will contribute to make the next meeting of the United States Bee-keepers' Union a grand success. Plan to go if you possibly can.

THE following clipping was sent to us by some unknown person. It is a gratifying piece of legislation, and we hope it will be contagious in our different legislatures until they all "catch" it as severely as the law-makers in Vermont did. It is just what we need:

One of the shortest laws we have seen is the following, which was passed by the last Vermont legislature, and approved Nov. 20, 1896:

SECTION 1. If a person sprays or causes to be sprayed, or puts or causes to be put, any Paris green, London purple, or other poisonous substance upon fruit-trees while in blossom, he shall be fined not more than \$40 and not less than \$10.

SEC. 2. This act shall take effect from its passage.

This law was passed at the request of the Vermont Bee-keepers' Association, which asserted that honeybees may be poisoned by visiting trees that are sprayed when in bloom. This assertion is, doubtless, correct; and since it is not necessary to spray fruit-trees when in bloom, this law will not prove injurious to fruit-growers. The best advice now is to spray after the blossoms fall, since we can then do most injury to the insects.

This goes to show that State and National associations will be heard if only the right methods are employed.

JUDGING from present prospects it looks as if there were going to be an enormous crop of honey from white clover. The tendency on the part of a good many will be to rush their honey off to the cities, and, of course, this will make a glut on the market. Bee-keepers ought to make every effort possible to dispose of their honey around home. Create a home demand. Make it as attractive as possible, and help the grocers to sell for you. In the next issue I will tell you about how to draw a crowd around a grocery window. I would tell you now; but the boss printer says, "No more room."

#### OUR BASSWOOD OUT-YARD.

It has been a very noticeable fact, during the white-clover year, that our home-yard has been much overstocked. During those seasons when we have a flow from basswood, the difference is very much less. Notwithstanding there is only a couple of trees in our whole orchard that has any buds on it, it seemed wise to "relieve the pressure" in the home yard by removing some of our best colonies there. The wisdom of this move was almost instantly apparent. Those same colonies at the home yard were gathering honey very slowly; but almost on the first day in the new location they began to pile in the honey. In four days they almost completely filled full-sized eight-frame sets of

extracting-combs. At the rate they were storing at the home yard it would have taken them almost two weeks. As the pressure does not yet seem to be "relieved" in our main apiary, we expect to take down another lot of colonies.

The home yard is located on one side (west side) of the town, and as the town is a mile wide and long the bees have no pasturage except on the west side. Then besides there are something like 150 colonies.

#### OFF TO CALIFORNIA.

"TIME and tide wait for no man," and the time to start for the Christian Endeavor convention at San Francisco has come. Business at the Home of the Honey-bees is still booming, and it is necessary to continue running our factory day and night to keep pace with the orders which come by wire as well as by mail. Usually business has slackened up so much by this time of year that there is opportunity for vacations. Most of them will have to be deferred a little this season. The San Francisco convention can not be deferred, and, having made my plans to go, I am off, feeling sure that the wants of our many friends will be carefully and promptly looked after by the many faithful helpers left behind.

I expect to be in Salt Lake City July 3d to 5th; Reno, Nev., 5th; San Francisco, care of Mechanics' Pavillion, July 7th to 14th; Los Angeles, care John H. Martin, box 152, from 15th to 19th; and, unless I change my plans, I shall be back to Medina by July 24th. I hope, in later issues, to tell something of my trip, and may also bring you some views, as I take along a Kodak with me.

J. T. CALVERT.

#### BETTER PURE-FOOD LAWS.

A SHORT time ago I indorsed the suggestion, made by some of the members of the new Union, that its first work, as soon as its funds should be available, should be to work for the passage of pure-food laws in every State in the Union where such laws were needed. I suggested that, in the city of Chicago, where adulteration is practiced more extensively than in any other city (for the reason that the State lacked a good pure-food law), the Union begin its work in Illinois first; and that C. P. Dadant and James A. Stone should be the men to buttonhole the members of the Illinois Legislature. In referring to this in the *American Bee Journal*, Mr. Dadant says:

Mr. Root has evidently more faith in my capacity as a lobbyist than I have myself, for I would make a sorry politician.

But, let me ask, is it really necessary to have more laws than we now have to prevent the sale of glucose under the label of honey? Can a man sell you salt for sugar, or dust for pepper, garlic for onions, or silver for gold, with impunity? If so, we are not a civilized race, and all the vaunts of the so-called progressive men are empty bubbles.

I am not a lawyer, and perhaps my reasoning goes astray; but, in my opinion, we need less laws than action.

I have no doubt that, if such laws as are already on the statute-books were rigidly enforced, the adulteration evil would be largely curtailed. But I understand the laws in Illinois are not as strong as they might be, or at least have been so garbled, or amended in the interest of the adulterators of food, that they are practically a dead letter, and that this is the reason why adulteration in Chicago is much more rife than in New York, where there are better laws. In Cleveland, for instance, it is very risky business to handle adulterated honey, or, in fact, in any city in Ohio, because we have good pure-food laws and an energetic food commissioner. The daily papers have contained accounts of the good work already done.

Let there be an equally good law enacted in Illinois, and efficient officers appointed to see that such laws are enforced, and the adulteration evil will begin to wane at once, just as it has done recently in California. In this latter State, you will remember that the effect of the pure-food law was almost instantaneous. I do not believe it is so much the *lack* of action as it is the *lack of good laws* to make an action, when begun, *result in something*. An action backed by a weak law seldom amounts to anything.

I have every confidence in Mr. Dadant's capacity. The henchmen of the food-adulterators have done so much lobbying that it is time, or will be, when the new Union has funds to back it, to do some lobbying too.

#### CANE SUGAR IN HONEY.

THE following letter received from Mr. W. A. Selser, an expert analyzer of honey, will explain itself:

Mr. E. R. Root:—In your issue for June 15, page 457, you make a statement that is not correct; and, knowing you are misinformed, I want to set you right. As you may know, I have taken a special course in analytical chemistry, in its bearing on honey; in other words, I consider myself a honey specialist. When honey shows 10 per cent of adulteration with cane sugar, it does show downright rascality, and proves the adulteration by man's agency of 10 per cent with cane sugar. I consider a man a rascal if he steals 10 cents from my pocket or 75 cents. I see no difference, except that the 10 cents won't do him much good, neither will honey adulterated with 10 per cent of cane sugar. I can explain just where this mistake occurs. It is in mixing up chemical and commercial terms. Pure honey (or nectar either) does not contain any cane sugar commercially speaking; that is, there is no sugar of any kind, as sold in the market, that is found in pure honey; but there is a very large percentage of sucrose, and sucrose is a chemical term for cane sugar, but it is not the cane sugar of commerce, under any circumstances. If you ask a chemist what sucrose is he will tell you cane sugar, but also tell you, not as you understand cane sugar of commerce, and has not the same chemical properties by any means. I am very sorry that another chemical word has ever been adopted to distinguish the difference.

I have been doing some expert work on honey adulterations for parties in comparison with general chemists, and my analysis has proven the most satisfactory. We also find a large percentage of what chemically is called reducing sugar in pure honey. This is another purely chemical term. Kindly correct your item and let the bee world understand that there is not one per cent of cane or

common sugar in pure honey. In this statement I defy contradiction. WM. A. SELSER.

Wyncote, Pa., June 22.

In referring to Wiley as authority for the statements I made on page 457, I had reference to a special bulletin on the subject of honey and syrup adulterations that was issued in 1892. The chief chemist, in speaking of the properties of pure honey, says: "The amount of cane sugar varies from nothing to eight to ten per cent, according to quantity of cane sugar in the nectar, and the extent of inversion to which it is subjected in passing the organism of the bee." In September of the same year, in GLEANINGS, page 688, Prof. Cook speaks of the difficulty of detecting cane-syrup adulterations, especially if they have passed the organism of the bee.

It may be, as Mr. Selser points out, there is a confusion in terms, and that the cane sugar of the market is different from that referred to by the chemist. The point that I made, however, still holds good—that, if one is dishonest enough to adulterate at all, he will not stop at 10 or 15 per cent, but will put in enough to make it pay. It does not seem right that small percentages of cane syrup or sugar, when found in honey, should be taken as absolute evidence of fraud, either on the part of the dealer or the producer. Witness, for example, the case spoken of by E. H. Schæffle in this issue. Only a small per cent of cane sugar was found in the honey, and yet it is evident that neither the producer nor the dealer meant to defraud.

#### THE BEE-KEEPERS' UNIONS; A REPLY TO PROF. A. J. COOK.

The following is just received from General Manager Newman:

*Editor of Gleanings:*—In your issue of June 15, page 449, Prof. Cook attempts to show that the members of the National Bee-keepers' Union did not understand what they were voting on at the last election. As my name is connected with that statement, allow me a few remarks.

I give the members of the Union credit for more sagacity than that, and I do not think the professor will dare to stand by his published statements.

In the first place, Prof. Cook makes this statement: "Mr. Newman says the old Union can not attack any evil but such as it has combated in the past." I beg to say that I never made any such statement, either to Prof. Cook or any one else, and I demand the proof, or the withdrawal of that assertion. Let me state a few facts which none can dispute:

Thirteen years ago the National Bee-keepers' Union was formed in order to defend bee-keepers in their rights as citizens of this republic. This it has done to the satisfaction of all. The Advisory Board has been consulted in every important case, and the General Manager has always been in perfect accord with the Board, there never having been a single disagreement. Indeed, there has been such unanimity up to this time that there has never been a dissenting voice relative to the course to be pursued. The instructions given by the Board in the past have been by me carried out to the letter; and what the Board decides to do in the future will be done; but I can assure Prof. Cook and every other member that neither the decision of the Board nor the vote of the members will be *disregarded*, as he advises in the third paragraph of the article in question. Such a thought is unworthy of a loyal member of any organization.

Last fall the Board gave every instruction necessary to the voting, how the ballots were to be disposed of, who were to count them, etc. For extra caution, as I imagined there might be a question, I directed that they be counted in the presence of a public official, and they were so counted and certified by the County Clerk, and the correctness of the count was attested by him under the seal of the Superior Court.

At Lincoln, Neb., last fall, a new "Union" was formed for doing the particular work of prosecuting the adulterators of honey. Its originators offered to amalgamate with the National Bee-keepers' Union, and that amalgamation was submitted to vote—the result being for amalgamation, 51; against it, 106—more than two-thirds vote against it, when it would have needed two-thirds for it to have carried. This was an overwhelming defeat.

As Prof. Cook says he voted against amalgamation, he voted with the great majority to continue the two organizations as they were before, even though he now says it was "senseless" to do so. He now intimates that the line of defense which has occupied the Union for the past 13 years is "no longer important." The many bee-keepers who are being legislated against all over the country, and are in danger of being fined or sent to prison, will certainly demonstrate that the defense of the pursuit is yet quite "important."

Again, the Professor says, "The old Union has got to fight living issues or die." Why, my dear sir, that is just what it has been doing all the while—living issues—yes, and for the pursuit, the very *right to live*—its very existence. It will still be "fighting living issues" when its enemies are no longer able to "kick."

The editor is right in saying that there is now as much room for the two organizations as formerly—for the old North American Bee-keepers' Association simply changed its name to be able to prosecute adulterators. The two lines of work are distinct—one to *prosecute* adulterators, and the other to "defend" bee-keepers; and, if the members so decide, there is no reason in the world why they should not remain separate organizations and each do its work, and prosper.

If the next meeting of the North American Bee-keepers' Association at Buffalo shall amend the rejected constitution so as to be consistent and effective (as indicated in my criticisms of that document), and it is desired by the Advisory Board of the National Bee-keepers' Union to resubmit it to the members, I shall be pleased to have it done at the next election. If not, then the two organizations should act in harmony, and let the matter of amalgamation drop.

If I am standing in the way, as Editor Root intimates on page 450, let the members of the Union elect Manager Secor, or some one else, and I shall gladly welcome my successor, as I have often plainly stated before. Until then, let us have peace.

THOMAS G. NEWMAN.

San Francisco, Cal., June 22.

If Mr. Newman did not utter the sentiment attributed to him by Prof. Cook, he has said something very much like it. I have not the time to go back over his official utterances, but I do find in the last report he says: "The National Bee-keepers' Union was brought into being for a special purpose—that of defending bee-keepers in their rights as apiarists." And again: "If the Union is to be reorganized to do this work, it will subvert its original purpose and mainly change its character." And again: "The funds in the treasury were accumulated as a defense fund, and should not be appropriated to other uses, without a full and well-understood vote." After this vote was taken, in an article in the *American Bee Journal*, page 291, Mr. Newman again says, with an air of triumph: "The National Bee-keepers' Union decided by an overwhelming vote that it would not consent to amalgamation nor to the use of

its funds for a purpose for which they were not created." It will be seen from the quotations above that Mr. Newman practically recommended that the Union continue in its old line of work, and the voters simply followed his recommendation; that, while the thought set forth in the quotations may not be precisely the same as that attributed by Prof. Cook to Mr. Newman, it is so much like it that, to argue the point, would be splitting hairs.

I am with Mr. Newman and Prof. Cook both in wishing for peace; I am also glad to note that Mr. Newman will be willing to submit the question of amalgamation, providing a union of the two organizations is still sought by both.—Ed.

A VISIT TO VERNON BURT'S APIARY; HANDLING SWARMS AT AN OUT-APIARY RUN FOR COMB HONEY.

ON Thursday, June 24, I called upon our old friend Vernon Burt (about three miles out), who has the reputation of securing a crop of honey every season, good, bad, and indifferent. I had not seen Mr. Burt this season; and as clover was unusually abundant, I had a curiosity to know how he was coming on. I strapped the Kodak on my back, mounted the wheel, and in a short time I was at his home yard. He had just returned from his out-apiary, that he is running for comb honey without an attendant, and I had caught him nicely at home. The bees were roaring and pouring in at the entrances, not in the pell-mell style as they do on basswoods, but in that quiet way they do during clover bloom. Said I:

"They tell me you have just returned from the out-yard. How do you manage about swarms during your absence without an attendant?"

"All my queens are clipped, and I make sure to see that they have plenty of room."

"Well, what do you do when swarms come out when you are away?"

"I let them come out and go back again. I visit the apiary about every day, and if they come out while I am away, they will also be likely to come out again when I am there, and it is *then* that I hive them."

"How do you hive them?"

"I move the parent hive to one side, put a hive of empty combs in its place, and on this I put the super that was on the old stand with its sections completed and partly completed. All the flying bees will, of course, go back to the old location."

"What do you do with the cells in the parent hive?"

"Let them alone. The colony will be so depleted that there will be no after-swarms; and the first swarm itself will not swarm again, but go right on storing in the supers."

"But don't you lose any swarms in that way?"

"Not that I know of," said he.

"How do you manage with swarms at home?"

"In the same way."

"Who looks after your bees here?"

"Mother. She lays a stick on top of the hive from which the bees came out, and lets them fly around till they get ready to go back. When I see a stick on the hive, or some unusual marking, on my return, I know what it means, and treat them accordingly."

"Have you come to any conclusion as to what size of hive for general purposes you prefer?"

"I did think at one time," said he, "that I preferred the ten-frame. I can get the bees in shape easier in the spring in that size than in the eight; but lately I have found that I can increase the bees up to the proper strength in the small hives, and they are more easily handled."

"Which hive do you use at your out-apiaries?"

"The new dovetailed eight-frame. I leave all double-walled and ten-frame hives in this yard."

"I notice your bees appear to be quite busy. You will probably secure 50 lbs. per colony."

"Oh, yes! I shall do as well as that, any way."

Then he opened several hives and showed me how his bees were working in supers. I noticed particularly that the bees were doing just as well on the outside rows of sections as on those in the center; and the sections in all parts of the super seemed to be keeping pace with each other. He went over his hives at random, and every one of the supers seemed to show this even building of the combs.

"How do you account for this?" said I.

"By the slow even flow from clover and plenty of bees."

I then took several snap shots with a No. 5 Kodak, and if all goes well I will show you how nicely Mr. Burt keeps things in and about his apiary. He seems to take things pretty easy, notwithstanding he has 125 rousing colonies at his home yard, and 100 at the out-yard.

"You do not seem to be in a great hurry or excitement," I said.

"No," he replied; "my queens' wings are all clipped; and before the honey-flow sets in I have every thing all in readiness—supers, sections, etc., so that, during the harvest, I do not have to be bothered with starting sections or any thing of the sort. I simply pile on supers, and watch the bees pile in honey; and the swarms, when they come out, we'll—I take care of them when I get ready."

"Do you use bee-escapes?"

"Yes, sir. I hardly know how I could get along without them."

And a man's foes shall be they of his own household.—MATT. 10:36.

□ In my last I told you that in my trip from Bannock to Barnesville I met with about the usual number of adventures, and I want to tell you something more about it. When I got off at Bannock Station I found the pike without any trouble, and started off in a southerly direction. It was sprinkling just a little at the time; but I always enjoy a sprinkle that will lay the dust; and when I am on a stone or graveled pike, so far as I am concerned I do not mind quite a little shower. Mrs. Root does, however, and she always objects to my riding in the rain unless I have on some old clothing that is of no account; but with this old clothing I am not presentable before strangers. Well, the gentle sprinkle changed to a pretty smart rain after I had gone a mile or two; and in looking about for shelter I discovered a large wide-open gate with a graveled drive that led up among beautiful flowers and shrubbery; yes, and in the midst of the shrubbery was a fountain playing. Of course, the summer shower made every thing look still more lovely; and the beautiful lawns spreading out on either side made me wonder for a time if I had not alighted upon enchanted ground. Come to think of it, I think there *was* some enchantment about the place. Now, do not look disgusted when I tell you that I soon discovered I had wheeled into the open gates of the Belmont Co. infirmary. It is a beautiful place, any way, and does credit to the people of that county. After I had had a pleasant chat with the gentlemanly superintendent the shower abated, and I took another graveled driveway out to the main road again. When I came *into* the grounds I was well satisfied that the main road or pike ran south or pretty nearly so. It might have been somewhat southwest. When I got on to the same road again (out of the "enchanted" ground) it seemed to be going westward; and by the time I had got to the bottom of the long hill, I was going just about north, as it seemed to me; and here the pike from Bannock struck the national pike just as I had been led to think it would; but it did not occur to me at the time that it was a little *strange* that I should come into the national pike from the *south* side instead of the north. Never mind; here was the pike, sure enough, and, no matter how I got there, the thing to do was to turn westward to Barnesville, and this I proceeded to do, feeling as happy as a schoolboy because I was away from business, and out on a vacation, with nothing to do but to have a good time.

Well, I admired the pike, people, and the scenery, even if it did rain. Finally, in order to be a little sociable with my fellow-men, more than because I had any doubt about the proper course I should take, I asked about how far it was to the Barnesville pike.

"Barnesville pike! Why, my good friend, you are going *away* from the Barnesville pike, and at a pretty good pace too. If you want to go to Barnesville you want to turn around and go the other way."

Now, I was as much astonished at this piece of information as if I had seen the sun setting in the east. (By the way, I have several times, in traveling, been greatly astonished to see the sun doing this very thing.) I reflected a little,

and finally, in a sadder and wiser frame of mind, I turned around and climbed the great long hill that I had just ridden down. The hill was wet and slippery, and I was having quite enough exercise without running down hills and then turning around and climbing them again just for the fun of it. I tried in vain to convince myself that west was in the direction the man said it was; but that stubborn part of a person when he is turned around would not be convinced. It made me think of the old adage, "A woman convinced against her will is of the same opinion still," and I mentally decided that, if any *woman* was as contrary as this other part of myself, she must be pretty bad indeed.

Permit me to digress just a little right here. I have before alluded to the fact that there seems to be in every one of us another person—a somebody who seems to be *involuntarily* managing for us. If we fall into the water this other self draws in a great big breath or a sort of gasp. I do not know what he does it for unless he thinks he may get under water and not find plenty of air, so he will lay in a great stock. If somebody goes up behind you noiselessly, this other chap makes a great start. You do not do it. In fact, you have nothing to do with it. You could not help yourself, even if you tried. This queer fellow is right along with you, sleeping and waking. You do not seem to be able to get along without him, and sometimes it is a pretty hard matter to get along *with* him. He and I had quite a tussle about this matter of getting lost. I was vexed because I had lost so much time and strength in going several miles out of my way, through the rain and mud, and I threw the blame all on him. Said I:

"Why, you might have known when you came into the big pike that you were to turn to the *right* to go to Barnesville. What on earth possessed you to turn to the left?"

But this fellow said:

"I think the left is the right way yet. I am sure it is straight west, no matter what the man said. I do not believe he knew."

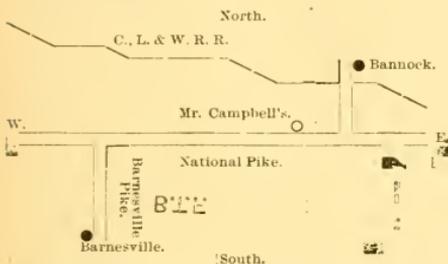

And (would you believe it?) this fellow was so contrary I asked another person. Then said I:

"Why, you stupid idiot, how *could* you get into the national pike on the south without crossing it somewhere, when you started out on the north side?"

At first this other fellow would not say any thing; but when I insisted on some sort of answer, he said he did not know how "we" got there on the south side of the national pike, but we certainly came into it on the south, and he would always stick to it. Did you ever hear of any thing more illogical or provoking? Of course, we two dropped the subject. There did not seem to be any thing else to do under the circumstances; but in spite of every thing I could do he would have it that we were going to Barnesville by traveling *eastward*; so I at last gave up; and when I got mellowed down a little I began to enjoy that beautiful pike. Of course, there were great hills to climb, and it was rainy enough to make the stone roadway a little slippery; but the grand country that showed itself at the top of every piece of rising ground was ample compensation. It seems to me I never saw so much white clover before in all my life as on that trip. I was told there used to be quite a business in keeping bees, but most of them had given it up in consequence of the repeated poor seasons. Just now everybody told me, however, they were having a great flow of white-clover honey.

The rain began to increase again; but I tied up my coat on my handle-bars so it was pretty

safe, and while in my shirtsleeves I greatly enjoyed "letting it rain;" in fact, I was feeling about as happy as I usually get, riding in that summer shower. I began to feel somewhat thirsty; but the great delicious breaths of that damp water laden air gave me a peculiar enjoyment that I have mentioned once or twice before. If one could get intoxicated on *pure soft water*, I do not know but I should call it a grand kind of intoxication. When I was breathing the heavy spray at Niagara I felt the same exhilaration. I finally came to one exceedingly long hill, still traveling east, as it seemed to me. The rain was increasing to such an extent that I knew I should have to stop at the first convenient dwelling. On top of the hill there was a very pretty little home, on the right hand side, and on the south side of the road—at least this other fellow I have been telling you about insisted it was on the south side, while I was traveling east to get to Barnesville. I have made a little diagram below to show you how I was situated.

You will readily notice the Cleveland, Lorain & Wheeling Railroad where it crosses the pike at Bannock. I have put on the points of the compass so you will have no difficulty in understanding the situation. When I left Bannock I was all square with the world. When I got to the national pike I was turned exactly around. If you take your book and turn it upside down you will see how I was turned around. I was going to Barnesville by traveling from left to right, or at least so it seemed to me in my turned-around condition. I reached the top of the great hill, turned down a little lane, and pushed my wheel into an empty coal-house or shed; but as it continued raining I told the good people who I was, and finally induced the proprietor to take his team and carry me to Barnesville; and the course he took seemed just like going back to Bannock; but yet we found Barnesville all right. Of course, I was turned around all the time I was there; and when I started to go home I left the place exactly as it seemed to me as I left Bannock the day before.

Now, my good friend Campbell, when he carried me with his team the day before, took a common road over the hills; therefore when I took the pike to go home with my wheel it was a road I had never traveled before; but I should get on to familiar ground when I reached Mr. Campbell's, where I had left some of my wet clothing.

Now comes the strange part of my adventure. In running from the Barnesville pike down to the national pike I went through the same kind of experience that I had in leaving Bannock. I started, as it seemed to me, going southward toward the national pike. When I reached it I was turned around again, and came into it from the *south*. Getting turned around twice brought me right.

When I discovered this second change I

thought of the man who was "clothed and in his right mind," and felt happy that I could make the rest of my journey by the points of the compass, and have them seem as they really were; and I began speculating, before I reached Mr. Campbell's, as to what the probable result would be when we came to the house where I had stopped in the rain the day before. In my present "frame of mind" I should find that house on the top of the hill on the opposite side of the road. I could not make it seem possible. Now, let us imagine that there was a discussion between myself and this stubborn, contrary other part of myself. I said:

"Now, look here, old fellow, you were pig-headed yesterday, and got me into a lot of trouble. I tried every way in the world to convince you by solid reason and plain facts that *east* was not *west*, but you would not give up. Now, sir, I have got you in a corner. When you come to Mr. Campbell's, where we stopped yesterday, you are going to find it on the other side of the road. Yesterday you declared he lived on the south side of the road. Now, when you find his house, barn, and coal-shed all moved over on the north side, what are you going to do? My good sir, how will you explain your inconsistency and foolhardy course?"

Would you believe it? The fellow would not say any thing, except that I would find the house on the south side of the road, just as it was the day before. In fact, it seemed to me I was traveling the same road I traveled the day before, or at least in the same direction, but the scenery was different.

Just before reaching Mr. Campbell's from the west I passed through one of the most beautiful valleys I have ever seen—in California, Arizona, Florida, or anywhere else. I do not know of a more beautiful spot on the face of the earth. I got off from my wheel and gazed my fill again and again; and then I drew in long breaths of life-giving air, and rejoiced that God had given me a human life to live. Yes, I rejoiced in the thought, even though God had seen fit to send this other fellow I have been telling you about along with me to trouble and perplex me, perhaps until the last day of my life.

I was nearing Mr. Campbell's home, and so I got off from the wheel and walked. If the whole face of creation was going to swing half way round all of a sudden, as they swing a locomotive on a turntable, I wanted to see the thing done; and so I kept saying to this other fellow, "Now, then, old chap, which way are you going to have it? Are you going to stick where you are now, or are you going to whop over when you see the old familiar landmarks of yesterday?"

□ I waited in breathless silence. I looked before me over the hill toward the place where the sun rises, and barely caught a glimpse of Bro. Campbell's house, and, as sure as you live, *his whole farm and surroundings* had been moved during the night to the opposite side of the road. This illusion was only momentary, however; for, just as I was going to crow over this other fellow, quicker than the wind I *myself* was swung around to the east, where I had been looking, and approached my friend's home in the very direction I went from it the day before. My right position of the compass was only short-lived. This other fellow triumphed, and I went all the way back to Bannock turned squarely around; but I inquired my way, so that I did not get into any more mishaps.

I have told this little story, dear friends, simply to illustrate to you the fact that there is a part of myself—yes, a part of your old friend

A. I. Root—that will not listen to reason or common sense. He is a dangerous adviser and an unsafe counselor; but yet I can not get rid of him. He has been with me as long as I can remember—at least I can remember of being bothered by getting turned around in certain localities, even as far back as when I was four years old; and that very spot where I was turned around at that time bothers me to this day. The sun does not come up in the right place, neither does it set where it does here in Medina, and I have to be constantly figuring and planning when I am in that locality unless somebody is with me to keep me straight.

I shall have to explain to the friends in Belmont Co. that I started on my trip with such a sudden rush that I actually forgot to look up our list of subscribers in that locality. And another thing, work was so much crowding here at home that I had absolutely no time for more than a flying trip. I was so much pleased, however, with the beautiful country, nice farms, and farmers' homes, that I contemplate another visit after we are through with our present rush. So don't think your old friend purposely passed by you.

#### GUIDE-POSTS.

My story in the present issue, about getting turned around, missing trains I expected to meet, etc., illustrates the great need of legible guide-posts throughout our land. Since the wheelmen have agitated the matter, however, we have a good law in this State, a copy of which is as follows:

SECTION 4734. The township trustees shall cause to be erected and kept in repair, at the expense of the township, at all intersections of the public ways of the township which lead to any city, town, or village, depot, or other important place or road, post and guide boards, displaying, in legible letters, the name, and indicating the direction and distance to all such places to which each of said roads leads.

Upon presentation to one of the trustees of a petition signed by ten free-holders, electors of the township, asking for the erection of a post and guide board at any designated intersection of the public highways of such township, and naming the inscription desired thereon, the trustees shall forthwith cause the same to be erected; and, failing or neglecting to do so for the period of sixty days, the petitioner may cause the same to be erected, and collect the cost thereof, not exceeding five dollars for each post so erected, from the township trustees.

SECTION 2. This act shall take effect and be in force from and after its passage.

In spite of this, however, I did not see a single guide-post on my route, although I looked carefully and anxiously for them.

---

## OUR HOMES.

---

And the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul.—GEN. 2: 7.

Dear friends, it may not be true that this perverse part of us that will not acknowledge the truth when it is presented to us (when we are "turned around") is the *evil* part of humanity, but it is certainly a stubborn and perverse spirit that exists in us all, or at least nearly all. When I can plainly see the sun rise and set, then this stubborn, unyielding spirit *usually* gives up, but not always, even then. Instead of confessing that he is wrong, he sometimes insists that all creation, including the sun itself, is out of joint rather than acknowledge his own blundering. As I am saying, it may

not be true that this unreasoning spirit is the spirit of evil that is within us all, yet in some respects it is much like it. A good Christian mother was reasoning with a little boy: She said:

"Sammy, aren't you sorry you were so naughty?"

But he shook his head. She repeated the question, and insisted on his answering. But he only replied that he was not sorry. Poor Sammy! He was perhaps depraved and wicked, but he was truthful; and even since I have got to be 57 years old I have had some experiences like Sammy's.

One day when I was tired out in both mind and body, and thirsty besides, and suffering also for my morning nap, I came into the house for my daily drink of hot water. I felt so tired and worried I would have gladly kept out of sight of anybody until I could reach my desired resting-place. But it did not seem possible unless I went without the cup of hot water I longed for. In securing it, something vexed me and I uttered some impatient words. Then came a conflict that lasted not only several hours, but I felt some of the effects of it for several days. The bad spirit said, "It surely is your privilege to have rest and a drink of water if you ask for nothing more, even if you do make somebody else a little trouble in getting it."

But another spirit (and I trust it was the ruling one) kept remonstrating by saying:

"Are you living for self or for the good of others? Are *you* going to take care of yourself through life? and when you come to die are you alone equal to the task of closing your dying eyes, or do you expect others to care for you when you can not care for yourself? Is your life in this world 'to be ministered unto or to minister' to others?"

And then comes the thought of my favorite text, about bearing not only our own burdens but those of other people, for Christ's sake. Christianity opposes point blank the idea of self and selfishness. At such times this other spirit, or "other fellow," will say:

"Oh! these nice texts are all very pretty to talk about in prayer-meeting. The idea of self-sacrifice is very well to sing about in hymns; but when it comes right down to living it out in every-day life, it is a good deal humbug and folly."

Yes, dear reader, it is true that I, who have been a Christian, or at least have called myself one, for 25 years or more, have something within me that suggests thoughts like the above. There is the selfish, unreasoning brute nature remaining still. Somebody has suggested that we were created brutes or savages, and would have remained so had not God himself breathed his spirit into us; and, in the language of our text, from that time forward "man became a living soul." That word "living," I think, should be taken in the sense that our Savior uses it in speaking of life—John 10:10: "I am come that they might have life, and that they might have it more abundantly." We do not understand by this simply animal life, but spiritual life born of God. The Bible enjoins us on nearly every page to beware of this selfish animal nature. In some places it is spoken of as the old Adam. In one text it says, "He that ruleth his own spirit is greater than he that taketh a city."

There is a suggestion that the God part within us should hold in check this unreasoning animal nature. This "other fellow" that I have spoken of in my travels in this issue would urge to strike back when we are injured. The God part says, however, "Love ye your enemies;

do good to those that hate you." In one of the recent prizefights it is reported that the crowd cheered on one of the parties, urging him to *kill* his opponent. In the last fight of all, it is said that even a *woman* used such an expression. Now, there is not only no Christianity in such an attitude of the human heart, but there is no sense or reason, and Christianity should be reasonable above all other things. A small boy pushed a larger one off from the walk into the mud, and soiled his clothing badly. The larger boy got up, but did not do any thing by way of retaliation. Somebody asked him why he did not give that boy as good as he got. He replied good-naturedly, "Then there would have been two suits of clothes to be cleaned instead of one."

The boy might have added that two tired mothers would have been obliged to clean up two suits of muddy clothing instead of one. This boy was not only a Christian but a philosopher. He let sense and reason guide him instead of the low passion of revenge.

A few days ago one of our boys came to me saying a man who works near him had struck him several blows. The man admitted he did, but said the boy called him a bad name, and for a time he insisted that it was the right and proper thing to do—that a man is justified in striking a boy just because the boy "sasses" him. How sad it is that so many people will still hold fast to this old-fashioned silly idea, that, to make things right, one man must strike another, or strike a boy, if he chooses, simply because of something he says! This "other fellow," of whom I have been talking, says, "Knock a man down when he abuses you." Sense and Christianity say, "Not so;" and *Jesus* tells us to turn the other cheek also when we have received a blow. After I had talked a while with these two friends of mine (the man and boy) the older one got the upper hand of the brute spirit within him so far as to tell me he was sorry that he let his temper get the better of him, and finally he told "*Johnny*" he was sorry, and asked his forgiveness. When he had got thus far, *Johnny*, not to be outdone—for a good spirit is catching as well as an evil one—said, "All right, I am willing to let it go, and I will ask him to forgive me for my foolish talk, which would not have happened if I had been attending to my work."

Many great and good men would have been almost perfect in their characters had it not been for their tempers. Our lamented friend and teacher, Drummond, in his little book, "The Best Thing in the World," says a bad temper is "the vice of the virtuous." I suppose he means by this that people who are so intelligent and well bred that they would be above any other sinful habit are sometimes guilty in just this one respect. I told you that this "other fellow," who *always* goes with me, had tormented and vexed me since I was four years old. Well, I can remember that this same "other fellow," or one of his relations, used to torment and vex me when I was scarcely more than *three* years old. We lived then in a log house with only one *other* apartment, and that was the woodshed. Sometimes when mother's boy was persistently bad she would say to me, "Amos, I think you will have to go out into the woodshed and stay there till you can get rid of the bad boy." Well can I remember of going out there and sitting down and endeavoring to quell the tumult in my childish heart. Sometimes mother would call to me, "Have you got rid of the bad boy yet?" But I think I was like Sammy. I could tell the *truth*, even if I could not drive out the evil spirit. So I replied, "Not yet, mother." In due time, however, I would come in smiling:

and in answer to her inquiry, "Are you sure the bad boy is all gone?" I could look up frankly and smilingly into her face and say, "All gone, mamma," and then I was happy, and *she* was happy too. I presume that old mother will read these very words, and remember the incident as vividly as I do now.

Our older readers will remember of a minister who was a bee-keeper who used to write for these pages some years ago. Although he was a minister of the gospel, and a good one too, he was all his life tormented by a disposition such as I have described. It even followed him at times into the pulpit, and again and again the evil one was driven away only by earnest prayer to the Savior and Redeemer of mankind. On his deathbed he said to his wife and children something like this:

"Dear friends, I feel and see that the evil one has finally lost his power and hold on me for ever and ever. Nevermore, through all eternity, shall I feel his touch and abiding presence again; and I glory in the thought of being with *Jesus*, where sin and temptation and remorse shall never reach me again."

Now, then, friends, the question comes home to you and to me, "Who is going to rule and guide—the 'other fellow,' who would lead us into trouble and snares, or shall sense and reason, and the influences of the Holy Spirit, lead your life and mine through the remainder of the years we have to live?"

Return, O Holy Dove! return,  
Sweet messenger of rest;  
I hate the sins that made thee mourn  
And drove thee from my breast.

#### REPORT ON THE NEW VARIETIES OF STRAWBERRIES IN THE MIDDLE OF JUNE.

The Marshall has done grandly, both under glass and in the open air. Brandywine is just beginning to ripen, and grow berries that can hang on the vines for two or three days, and still be so firm and solid that they may be tumbled about like potatoes. The Wm. Belt is well loaded with fruit, but only just beginning to ripen. Margaret has given us some of the largest and finest berries I ever saw; but the Nick Ohmer caps them all, not only in great size, but in producing berries as round and symmetrical as a peach, and pretty nearly the size. I kept one on the vines for three days to show to visitors, and it was very solid and firm when picked. It weighed almost an ounce and a half. This was from a plant set late last fall. The runners were not picked off, and it was allowed to mature a full crop of fruit. Carrie, a seedling of the Haverland, is a much larger berry than "her mother," and considerably firmer, and I hope as prolific, although I am not certain, for I had only half a dozen fall-set plants. The shape of the berry and the appearance of the variety are almost exactly like the Haverland. Clyde started out to give a great lot of berries on spring-set plants. One of the plants set so full, in fact, that, when it got its great cluster of berries almost ripe, it—up and died! I suppose it was the hot weather that did it while the plant stood by itself unprotected. It seemed almost like "cruelty to animals" to let it undertake to ripen such a big lot of berries. Now, when you are testing new plants take a warning from the above.

## WHO WOULDN'T BE A GARDENER?

Sometimes I think it strange that there is anybody in this world who does not have a garden; and then at other times, when prices are low and we can not get the cost of our stuff, and every thing seems to go wrong, I do not wonder that so many people say they would rather buy their stuff, what they want, than to be bothered with any sort of garden. Well, yesterday and to-day have been bright days for the gardening business. After a severe drouth we had a succession of refreshing showers. Our beds were so full of plants that I began to fear we should never have customers for all of them; but after the shower the people came in crowds for plants. I stationed myself near the garden, and called in help for the boys, and it kept me as busy as I could be in answering questions and giving directions.

In putting up vegetable plants quite an amount of time may be saved by a little preparation beforehand, and the exercise of some study and brainwork. Unless I am around to take charge of things, our boys will go with the customer and let him select the plants he wants. Then they will take them up and carry them to a stand or table, and sometimes right into the store, and they used to tie them with wrapping paper and string. But I have shown them a much better and cheaper way. Get some stout paper bags, such as hardware dealers use to wrap up nails, etc., with. Have three or four sizes of these bags at different points, and especially near the beds where the plants are growing. When a customer calls for plants, and tells how many he wants, select a paper bag of the proper size, put your hand in it and straighten it out so the top will stay open; then take up your plants and lay them in a heap, shaking off most of the dirt as fast as they are taken from the soil. When you get the right number, take both hands and press the roots up into a small compass, letting the tops come up between the wrists. Now, if your paper bag was opened properly, and is of the proper size, you can put the ball of roots right down to the bottom. The paper bag protects them from the air, keeps the dirt from rattling off, gives the tops just enough ventilation, and not too much to have them keep without wilting. If you do up your plants first, and handle them twice, you rattle the dirt off a good deal more, and expose the roots to the drying effects of the air. I suppose, of course, no plant grower would undertake to remove plants without first thoroughly soaking the bed with water. Even after we have had a long rain we think it best to soak the ground, either with the hose or watering-pot; then with a good stout trowel push clear under the plant, and loosen it up so all the small fibrous roots will come out along with it. A smart boy who is trained to the business, and carries his paper bags along with him whenever he goes for plants, will wait on a dozen customers, and have things in better shape, in less time than some people would take to wait on a single customer.

While the "boom was on" for plants people began to go for the strawberries lively. They had just got down to 8 and 9 cents, and somebody in the store was complaining that there was not a quart of strawberries to be had, and customers waiting. But there were some big rows of Bubachs, Marshalls, and Brandywines waiting to be picked; and in a twinkling we had a lively time around the strawberry-beds. We might have put up a notice, "Beautiful strawberries picked while you wait." In fact, that is what we did do. With myself on hand to show off the plants, and give the names of the different varieties, it was not at all surprising

that customers would say, "Well, I think I will have a quart;" or, "Why, I will take two quarts of those great big ones, if you give heaping measure like that," etc.; and just when I began to fear there were more strawberries than we could easily get rid of, they were all cleaned up—in fact, so much so that the boys, in their efforts to get a few more quarts for a customer, picked some that were rather green. Oh how the new varieties have brightened up and enlarged since the rain!

This year we are testing our new varieties, as I have explained, by putting them in our plant-beds 18 inches apart. This is just about right; and if you do not step on the beds at all it gives plenty of room for putting down runners. It is wonderfully interesting to me to note the peculiarities and desirable traits in the different candidates for public favor. For instance, Clyde, that has been considerably talked about, is really bearing a wonderful crop—wonderful considering that the plants were put out only this spring. The Ideal, planted at the same time, is giving the handsomest berries in shape and color, almost, that one ever saw. The berry called "Pet" (I do not know where it came from) is the sweetest berry I ever tasted. It really brings forth an exclamation of surprise when one puts it into his mouth. I do not know how good a berry it will be, for all I have mentioned above were put out last spring. Brandywine and Wm. Belt are both doing wonders. These were planted out late only last fall, and yet an acre of such berries as they are bearing would be a pretty nice thing to have, I assure you. Great big berries, with the boxes heaped up, bring just about double the price of ordinary varieties, such as Warfield and Haverland.

Some years ago Peter Henderson recommended a plan for market-gardeners, for growing strawberries. It was to put out potted plants in the fall (of course the earlier the better), on rich ground where some crop had been removed. All the runners were to be kept off, the plants stimulated to their utmost, and then, after they have borne just one crop, eight or ten months after planting, plow them all under and do it over again. On account of the difficulty of working up the ground thoroughly while it is occupied by a crop of berries, and also the tremendous expense of weeding out a weedy strawberry-bed, I often think I should like Henderson's plan pretty well. Work your ground up deeply and thoroughly, after any spring crop comes off, then plant your strawberries, get one crop, and then do it over again.

At present writing, June 22, all of our strawberries may be said to be in their prime; and I tell you we have got some wonderfully nice berries among the new ones that are now before the strawberry-loving public. There are so many splendid berries I really feel troubled in deciding in regard to them. The Marshall has done grandly. The berries are large, there are lots of them, and they are quite early. The color is beautiful, the shape is almost faultless, and the flavor delicious. Our bed where we grew them under glass is even now putting out blossoms for a moderate crop to ripen along in July, just as we had them last year. But, why is not the Marshall good enough? Well, the Nick Ohmer and the Margaret are considerably larger than the Marshall. On my small experimental bed, however, they are not bearing as many berries as the Marshall; but it should be remembered that they were planted late only last fall. The Brandywine comes in just after the Marshall, and the berries are immense; but it does not furnish the quantity that the Wm.

Belt does coming a little later. The plants were, however, put out late last fall, and may not be up to their best; but the Wm. Belt was also planted late last fall. This spring they did not seem to have withstood the winter nearly as well as the Brandywine; in fact, I was somewhat disappointed in regard to its hardiness. But they began to grow, and, almost before I knew it, had put out great fruit stems, and now it is ripening the largest berries I ever saw in my life; and in quantity they are piled up almost like the Haverlands.

As Matthew Crawford says, the first berries to ripen are a good deal cockscombed; but after that you get berries as nice in shape as the Marshall or Nick Ohmer. Just a word about these first cockscombed berries. We had one that seemed to be great flat berries united. There were four lobes to it, in fact, and it was a good deal the shape of a cube. Its weight was  $2\frac{3}{4}$  ounces—I think the heaviest berry I ever grew. If you take a peach or an apple weighing  $2\frac{3}{4}$  ounces, you will get some idea of its size. The cube was  $2\frac{1}{2}$  inches on each side. Of course, the berry had to be eaten as you would an apple, and it took several bites to eat the whole of it. At present writing there are lots of these berries that are simply great chunks of fruit. It is almost as sweet as the old Sharpless, and they are good eating without any sugar at all. When one is tired and thirsty, say along between ten and eleven o'clock, three or four of these large berries make quite a nice little lunch. In Mr. Crawford's spring catalog he answers the question, "Which is the best strawberry?" as follows:

I will say that the Wm. Belt is the best berry that I have ever grown here.

I do not know but I pretty nearly agree with him. He adds further:

For vigorous growth, great productiveness, large size, and good quality combined, I never saw its equal. Under high culture, the first berry on the fruit-stalk is apt to be cockscombed; but who will object to having a few of their berries flat and three inches in diameter? I am not sure that I ever saw two misshapen berries on one fruit-stalk. All but the first one are uniformly of good shape. The color can not be improved. It is neither crimson nor scarlet, but bright, glossy red.

Now, mind you, from my standpoint this 22d day of June I feel like placing the Wm. Belt equal to anything I have ever come across in the way of a desirable berry. Of course, we want some earlier berries, before the Wm. Belt begins to ripen, and we are just now making our last picking on Michel's Early.

Our friend Dan White, of New London, O., was here a few days ago, and he tells me he is putting out an acre and a half this year on the plan I gave on page 782, Oct. 15, 1895. He says there is not a ripe berry to be found among his Gandys as yet, and he places the Gandy as the latest berry to ripen he has ever found.

By the way, the berry that I was so well pleased with last year, and that came as the Great American (see p. 508, issue of July 1st, last year), I am obliged to think is only our old friend Sharpless under another name. The berries are now in their prime; and the reason they were so much later than every thing else last year was on account of their being grown in such a thick solid bed. The rank foliage and the close planting kept the sun out so as to make the berries late. Well, even if it is the Sharpless the incident has opened to me a new possibility in strawberry culture. Make your ground exceedingly rich (it had better be heavy clay soil underdrained), then let the plants grow all over. Let them stand just as thick as they have a mind to. Perhaps some currant

bushes or something of the sort to help shade the ground will assist in making them backward. Now, notwithstanding its cramped circumstances, the Sharpless, after all other berries are gone, will produce great monstrous fruit. Of course, the berries will not be colored up very much, or at least not to amount to much; but the Sharpless is very nice to eat when it is partly ripe. But you will find a purchaser at good prices while other berries are too small to bother with. Besides, such a plantation would be little or no trouble. When once started it would choke out every weed that attempts to grow. I have now in bearing some of the genuine Great American which I received from the originator a year ago. It is a very nice large berry, much like the Marshall, but later; but the plants which were set out last fall do not bear as many berries as the Wm. Belt put out under similar circumstances.

#### SUB-IRRIGATION FOR STRAWBERRIES.

At this date, June 26, right here, we are having a pretty severe drouth, and it comes almost right in the midst of our strawberry crop. It affects us worse because the ground was packed down so hard by our excessive rainfalls that it cracks open and does much damage except where the surface has been fine-tuned by cultivation. Our choice strawberries that were planted out late last fall, and which are in narrow rows, we have cultivated and fined up the space between the rows, so as to obviate the drying and cracking, at least as much as we could without interfering with the mulch. The mulch of straw and potato-tops is not sufficient to prevent damage entirely. Our berries are drying up, the greater part of them, and look as if they had been cooked. Had the soil been worked up down deep after the heavy packing rains, the damage would be but slight. In fact, corn and potatoes planted in well-pulverized ground after the rains are not suffering perceptibly. We have just had an opportunity of testing the benefit of water in one of our sub-irrigating beds. It is planted to strawberries, but no water was turned on during the spring. I purposely left the bed until the berries began to be small and dried up somewhat. Then we turned on water until it came up from below, so as to dampen perceptibly the surface.

In 48 hours the whole aspect of the bed was changed. Every green berry began to fill up and expand wonderfully. Those that had begun to shrivel, plumped out, looked very glossy and juicy, and they were juicy too, I tell you.

There has been considerable said about selling strawberries at the low price of 4 and 5 cts. a quart. Well, that is pretty low; but if we had our beds so arranged that we could water them from below, letting the water gradually rise up until it comes just near enough the surface, I do not know but we could do a pretty good thing by selling water at 4 or 5 cents a quart. Choice varieties like the Brandywine, Wm. Belt, Marshall, and others, bring 6 and 7 cents a quart—sometimes 8.

By the way, the latest berry to ripen on our ground this season is the Champion of England. I think the location of the bed, however, helped to make it late. It was on the north side of a grapevine-trellis, and protected from the sun pretty well all through the day; then it was mulched with potato vines last fall, so that the plants had to creep up through the vines to get out into the open air. This helped to make them late. This morning we made our first picking. A good many of the finest berries were scattered through the potato-vine mulching. The drouth had hurt them but very little, and the great clean luscious berries hidden

away in the dried-up potato-vines were in beautiful shape. To get berries extra early they should be in thin rows, or, better still, in hills, and we should work the ground without any mulching until just before the fruit ripens; but for a very late berry, heavy mulching is needed all through the spring to keep them back, and then the shade of a grapevine or of trees will also help. This, with heavy matted rows, will enable us to have fine large berries after the others are gone; and my impression is, that sub-irrigation, with the water let on at just the right time, will also help to prolong the crop.

#### WINTER OATS—ONE OF MY FAILURES.

Perhaps I have been telling about some of my successes a little too much, while I have said little or nothing about recent failures. A year ago I reported that our Rural New-Yorker winter oats came through all right, or with but little injury. We saved the seed and put in between two and three acres last fall. They came up promptly and showed a good stand all winter, although I remember of several times thinking they looked a little queer for oats. They wintered perfectly, and this spring we had a magnificent stand. In some places they were a little scattering; but they stood out so they just kept down the weeds and every thing else. When they began to head out, my teamster suggested that the cold winter had turned the oats into chaff. I told him what the experiment stations and agricultural papers say about it; but he said he knew all about that; but when I saw a whole field of grain turn into chaff he thought I probably might have my faith shaken a little, or something to that effect.

My oats kept growing, and they kept looking more peculiar. There was some real old-fashioned chaff among the oats, and I sent a man over to the field to cut it out. Another friend suggested there were two kinds of chaff, and that my winter oats looked very much like one of the kinds.

About a week ago, when the oats came into bloom and there were going to be three or four grains where there should be one of oats, I was obliged to give up that something was the matter. I sent samples to our experiment station and to the Rural New-Yorker folks. I also sent a sample of the oats I sowed, and told them something like this:

"We sowed oats such as we send you by this mail, and we have a beautiful crop of green stuff such as I also send you by this mail. We sowed oats, and shall we reap chaff? If not, what shall the harvest be?"

After my two samples and missives had gone I began to feel still more uneasy. I went down to the seed-room and asked for a sample of our winter oats. I showed them to the teamster, to let him see that they *were* oats and nothing else; but while we were looking them over he said, "Why, there is *some* chaff in this oats, as sure as you live." Then I looked over the handful, and, to my astonishment and dismay, I found perhaps one grain in five or ten that was a large kind of chaff. We could easily sort out the chaff from the oats; and my present explanation is that the cold winter killed out every grain of oats and left the chaff. In fact, when we plowed it under we could not find a single stalk of oats in the whole two or three acres; but there was a nice even stand of chaff. It seems to me almost incredible that the few chaff grains should have made so perfect a stand; and it seems also exceedingly strange that not one grain of *oats* survived the winter.

As soon as I discovered the chaff, of course I

notified both the Rural New-Yorker and the experiment station in regard to the matter. Prof. Hickman replied, before he received my second communication, as follows:

*Mr. Root:*—I am sometimes mistaken, but I think you will have sown oats and reaped chaff. I think I am entirely safe in arriving at the conclusion that your experience with the winter oats will be like ours at the station; and that is, that your oats have frozen out, and in their place you have chaff. This is not oats turning to chaff, but simply history repeating itself. Cut the chaff and make hay out of it before it gets too hard, and before the seed ripens or even matures sufficiently to reproduce itself. I thank you for calling our attention to this matter. It is one of interest.

Wooster, O., June 15. J. FREMONT HICKMAN.

Permit me to add further in conclusion, that no such chaff as this has ever been seen before on our premises or in this neighborhood. The stuff was promptly plowed under while in full bloom, June 18, and the ground planted to Thoroughbred and Freeman potatoes.

---

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

### NEW AND DESIRABLE VARIETIES OF STRAWBERRIES FOR IMMEDIATE PLANTING.

We have decided to furnish the following kinds by mail postpaid, at prices given, but can not promise to ship promptly, for the demand may be greater than the supply. All we can do is to promise to fill the orders in rotation. If the drought continues that is with us now, the only way we can furnish plants will be to irrigate, and this of course will make them more expensive. The first three mentioned are offered by the originators only, and at from \$2.00 to \$3.00 per dozen. In view of this we think our prices are moderate as follows:

Carrie, Darling, Earliest, and Nick Ohmer, 15 cts. each, or \$1.25 for 10 plants. You may have all of one kind, or a mixed lot, of all these, as you choose.

Margaret will be 10 cts. each, or 75 cts. for 10 plants.

Brandywine, Marshall, Wm. Belt, will be 5 cts. each, or 40 cts. for 10.

We shall not be able to furnish them in larger quantities than the ten lots until later on. We will let you know when we can make better prices. By way of description we will say Carrie is a seedling of the Haverland, but the berries are much larger and firmer, and the plants seem to be stronger growers. The Earliest is away ahead in point of earliness of anything I ever met before. During the past spring we were obliged to cover the blossoms with glass to prevent them from being killed by frost. For such an early berry it is fairly productive. The Darling is much like the Earliest, but a little later. The berries have a wonderfully enticing rose color when only partly ripe. One of our six original plants bore a very large lot of berries. Nick Ohmer gave us one berry as large as a small lemon, and as faultless in shape as a lemon. As we received the plants only last fall we can not as yet say how productive they will be.

Brandywine, Marshall, and Wm. Belt have been sufficiently described in this and previous issues. We are going to try hard to mail the plants promptly, whether we have dry weather or not; and when you get them we hope you will give them shade and water, so that every plant shall live, whether you have dry weather or not.

A single strawberry-plant put out in July, watered and shaded and cared for, should make at least a dozen before winter comes; and with such plants as the Earliest, Michel's Early, Warfield, and others, that make plants rapidly, I think I could, in our rich plant-beds, increase one plant to 50 or perhaps 100. Of course, this requires much care and pains. During a drought I would not only use water, but shade the plants with cloth in the middle of the day; so you see that, even though you do pay a pretty good price for these choice new varieties to start with, if they should continue to find favor you

would make a very good thing of it raising plants; and, besides, you would "learn the trade" while you made something. See?

STRAWBERRY SEEDS FOR THOSE WHO MAY WANT THEM.

Notwithstanding the fact that there are probably more good new varieties before us now than we shall be able to take care of in the next ten years, there are still many persons who want to try their hand at new varieties. For the benefit of such we have put up seeds from overripe fruit of the following varieties: Sharpless, Warfield, Edgar Queen, and Marshall; and if you were to try your hand at putting in the seeds you would coincide as our women-folks did, that we could not afford a very big lot of seeds for a nickel. It is a rather delicate matter, if I am correct, to get them to grow. Sprinkle them on the surface of some very rich sifted compost or woods dirt; then cover them lightly with sifted moss, just as you would celery plants, and keep the moss damp until your little plants are up. Price of seeds of above kinds 5 cts. per packet.

THE GLEANINGS CONTRIBUTION FOR THE STARVING PEOPLE IN INDIA.

Mr. and Mrs. H. J. Bennett, Fair Haven, N. Y., \$23.60; R. Noren, Waverly, Neb., \$5; Mr. Booth, Medina, O., \$5; Albert Eckermann, Muskegon Heights, Mich., \$1.

## IF YOU WANT BEES

that will just "roll" in the honey, and that are wonderful red-clover workers, also gentle to handle and exceedingly hardy, then try **MOORE'S STRAIN OF ITALIANS**, the result of 18 years of careful breeding.

Warranted queens, 75 cts. each; 3 for \$2.00; per doz., \$7.00. Select warranted, \$1.00. Strong 3-frame nucleus, with warranted queen, \$2.50. Safe arrival and satisfaction guaranteed. Circular free. Those who have never dealt with me I refer to A. I. Root, who has purchased of me over 850 queens.

J. P. Moore, Morgan, Pendleton Co., Ky.

**BEES** FOR SALE. In 8-frame Dovetailed hives, queens from imported mothers. Price \$3.00 to \$4.00 per colony.  
EDW. SMITH, Carpenter, Ill.

"Weren't **POUDERS**?"

SEE THAT WINK?  
BEE SUPPLIES.

Nothing in the market approached the value of these bicycles at the former prices; what are they now?

**POPE MFG. CO., Hartford, Conn.**

Catalog free from any Columbia dealer; by mail for a 2-c. stamp.

**B. Hendrickson, Agent.**

Medina, Ohio.

### Are You Going to Buy Apiarian Supplies or Bees?

If so, You Want the Best.

This is the only quality we offer. Our prices are right, and our '97 catalog describing them, and the management of bees, is yours for the asking.

We carry a large stock, and can ship promptly. Freight is a big consideration, often amounting to 20 per cent of the value of goods. Let us quote you prices on what you need, delivered at your station,

### Freight Paid.

They will cost but a trifle more than others charge at the factory. Our aim is to please.

Apiary,  
Glen Cove, L. I.

I. J. STRINGHAM,  
105 Park Pl., N. Y. City.

**Queens,**

Either Golden or Imported by return mail. Untested, 75c; Tested, \$1.00; Breeders, \$2.00.  
W. H. LAWS, Lavaca, Ark.

### Don't Neglect Your Bees.

Bee-keeping may be made uniformly successful by judicious feeding. It is just as important with bees as with other stock.

Success in feeding depends very much on the feeder used. When you have tried the

**Boardman Atmospheric  
Entrance-feeder**

you will be convinced of this.

For descriptive circulars and price list, address

**H. R. BOARDMAN, East Townsend, Ohio.**

**QUEENS.** Either 3 or 5 banded, 60 cents each; 6 for \$3.00. Nuclei and supplies cheap.  
**CHAS. H. THIES, Steeleville, Ill.**

BEE-SWAX.

Those having beeswax to dispose of will do well to ship at once. For any thing we now see we will decline the price at least 2 cts. a pound very soon. The set-off for its heavy consumption in comb foundation is very nearly over; and it has been the experience of past years for prices to rule lower during the late summer and fall. We are now paying 25 cts. cash, 27 in trade, delivered here; but we can not promise this price longer than the next two weeks. If you have enough for a shipment, send it along at once without waiting to accumulate more.

## COMB FOUNDATION OUTPUT.

Our output of comb foundation so far this year is away in advance of any year so far in our history. It is already more than double what we made in a whole year two and three years ago. It is simply phenomenal, the demand we have had, and the satisfaction it gives is daily attested by kind words of praise and admiration which we receive in almost every mail. Truly, if it were not for the inventions of Mr. Weed, and the consequent improved machinery for turning out at a very rapid rate this improved foundation, our capacity would not have been equal to such an increased demand, nor would the demand have increased so much except for the superior qualities of the Weed New Process foundation.

## SECTION BOXES.

Our output of section boxes is also far in advance of any previous year in our history. We have made, during the three months of April, May, and June, more sections than we turned out during a whole year three and four years ago. Notwithstanding the fact that some manufacturers have offered these goods at lower prices, we have not been able to make sections as fast as they were required, and have called on two other factories to help us out to the extent of half a million. Lately we have not been able to supply the No. 2 grade in the quantities that they have been called for, and some who order No. 2 will be compelled to take No. 1 instead.

If any of our readers can use  $4\frac{1}{2} \times 4\frac{1}{2}$ , 7-to-foot, we have some thirty or forty thousand of this size in stock which we can ship promptly. We have also a surplus of  $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ , both 2 and 4 openings.

## DRAWN FOUNDATION.

Finally we have our dies completed  $\frac{3}{4}$ , and in operation, making drawn foundation. We find that our hydraulic machinery for operating the dies is inadequate to the pressure for using the dies full size, and we are making pieces  $4 \times 4$ , just right to fill a section; and until we get more powerful machinery we are not prepared to furnish it larger nor in very large quantities, but such as we can furnish will be much superior to samples from the former dies—lighter and more delicate. It is already too late to test it in the production of early honey; but the tests on a late honey crop, which generally comes in more slowly, will be more severe.

We offer the drawn foundation in  $\frac{1}{2}$ -lb. packages at 75 cts. with other goods, or 90 cts. prepaid; three pieces,  $4 \times 4$ , to fill a section, for 10 cts.; by mail, 12 cts.; 24 pieces, 50 cts.; by mail, 60 cts.; 10 pieces, 25 cts.; by mail, 30 cts. If you have prejudices or preconceived notions in regard to this drawn foundation, send for a sample from the last dies and see it and test it for yourself, and then you will be able to speak intelligently in regard to it. It is not too late to test it this season in very many localities.

**QUEEN**, 60 cents; three or more, 50 cents; dozen, \$5.00; tested young, 75 cents.

J. B. CASE, Port Orange, Fla.

**FOR SALE**.—Large American fruit- evaporator cheap.

EZRA G. SMITH, Manchester, N. Y.

**WHITE** and black Minorcas; eggs, \$1 per 15. 1st-class stock. SARAH SHAW, Winthrop, N. Y.

## Three Car Loads.

My third car of goods from The A. I. Root Co. has arrived, and I am prepared to fill orders for regular goods by next train at Root's prices. Send for my 36-page catalog, or send me a list of goods wanted and I will make you bottom prices.

GEO. E. HILTON,  
Fremont, Mich.

## The Adels, The Adels!

"Sammonsville, N. Y., June 21, 1897.  
"Find \$5.50 for queens. The best stock in 1896 out of 130 was an Adel. The best stock this year out of 165 is an Adel from an 1896 queen from you."

Adel Queens \$1. New catalog now ready.

HENRY ALLEY, Wenham, Mass.

## Requeen, Requeen, Requeen.

Now is the time; queens are cheap.

Best untested Italians 50c, \$6.00 per doz.; tested, 75c, \$9.00 per doz. These are "Shaw queens." Try them. Every one knows they are good as the best. Orders filled by return mail, and satisfaction guaranteed.

J. W. K. SHAW & CO.,  
LOREAUVILLE, LA.

**500 UNTESTED QUEENS** from imported Italian mothers. My queens produce gentle bees and superior honey-gatherers. Fifty cents each; \$6.00 per dozen. How many do you want?

W. C. FRAZIER, Atlantic, Iowa.

## For Sale.—Bees and Queens.

Queens 50 cts.; nucleus, two-frame, with queen, \$1.50; one-frame, \$1.00; three-frame, \$2.00.

Mrs. A. A. Simpson, Swarts, Pa.

**ORDERS** filled by return mail for the choicest untested Italian queens at 60c each. Can furnish 1, 2, and 3 frame nuclei.

A. I. ROOT COMPANY'S SUPPLIES. Send for 36 page catalog.

JOHN NEBEL & SON, High Hill, Mo.

## Wants and Exchange Department.

**WANTED**.—To exchange 25 colonies of bees for bicycles or offers. Also large American fruit- evaporator cheap.

EZRA G. SMITH,  
Manchester, N. Y.

**WANTED**.—To exchange Parker shot-gun (new), cost \$50, and Italian bees for high-grade bicycle or offers. Write at once if you want a bargain.

R. A. PROVINS, Point Marion, Pa.

**WANTED**.—To exchange for something useful, two fine bloodhound pups 5 months old.

Claud Brillhart, Oakwood, Paulding Co., O.

**WANTED**.—To exchange a 5x8 R. O. Co. camera, fitted with Lowe shutter (time and instantaneous)—a fine instrument in A1 condition—for nuclei, camera  $3\frac{3}{4} \times 3\frac{3}{4}$  (Hawkeye or Kodak preferred) or offers. Write J. W. AMBROSE, Box 862, Urbana, O.

## Black and Hybrid Queens for Sale.

I have twenty hybrid queens for sale at 25 cents each or 5 for \$1.00. Address ALBERT HINES, Independence, Buchanan Co., Iowa.

United States Bee-keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest commission-man.

MEMBERSHIP FEE—\$1.00 PER ANNUM.

Executive Committee.

PRESIDENT—GEORGE W. YORK. VICE-PRES.—E. WHITCOMB. SECRETARY—DR. A. B. MASON, Station B, Toledo, Ohio.

Board of Directors.

E. R. ROOT, E. WHITCOMB, W. Z. HUTCHINSON, E. T. ABBOTT, DR. C. C. MILLER, C. P. DADANT.

General Manager and Treasurer.

EUGENE SECOR, Forest City, Iowa.

Next Annual Meeting at Buffalo, N. Y., Aug. 24—26, 1897.

Honey Column.

CITY MARKETS.

MILWACKEE.—Honey.—The market is quiet. The supply is equal to all demands. There is quite a little stock of old comb honey, but nearly all of the common grades. The fancy nearly all sold off, while the common quality is hard to move at any price. Can quote white choice 12@13; white common, 7@11; extracted white, in pails and cans, 5½@6; dark, in pails and cans, 4½@5; white, in b-rs, 5@5½; dark, in barrels, 4@4½; beeswax, 25@28.

A. V. BISHOP & Co., Milwaukee, Wis.

July 7.

CLEVELAND.—Honey.—Fancy white, 12½; No. 1 white, 10@11; fancy amber, 9; fancy buckwheat, 6@7; beeswax, 28@30.

A. B. WILLIAMS & Co., 80-82 Broadway, Cleveland, O.

July 7.

COLUMBUS.—Honey.—Old crop white clover, 12@12½; amber, 7½; dark, 6@7. No new honey offered. Market extremely quiet.

THE COLUMBUS COM. & STORAGE CO., 409-413 N. High St., Columbus, O.

July 7.

CINCINNATI.—Honey.—There is a fair demand for old and new extracted honey, and prices range from 3½@6, according to quality. New honey is coming in plentifully, and some of the finest clover we ever saw. We are receiving the best light honey from the Southern States we ever did. We had a number of arrivals of fine new comb honey which we quote at 12@13. Demand for beeswax is fair at 22@25 for good to choice yellow. CHAS. F. MUTH & SON, Cincinnati, O.

July 7.

BOSTON.—Honey.—Fancy white, 13; No. 1, 11@12; amber, 10; white extracted, 7; amber, 5@6. Beeswax, 26.

E. E. BLAKE & Co., 57 Chatham St., Boston, Mass.

July 7.

KANSAS CITY.—Honey.—Fancy white, 13@14; No. 1 white, 12@13; amber, 11@12; dark, 8@10; extracted, white, 5@5½; amber, 4½@5; dark, 4@4½. Beeswax, 30.

C. C. CLYMONS & Co., 423 Walnut, Kansas City, Mo.

July 8.

CHICAGO.—Honey.—Not any new comb honey on the market. Extracted is offered freely. A few sales are being made on a basis of 5½@6 for best white. Amber, 4@5, with dark grades selling equally well as the white. Beeswax, 26@27—all offering being taken. R. A. BURNETT & Co., 163 So. Water St., Chicago, Ill.

July 7.

ST. LOUIS.—Honey.—Fancy white, 12@12½; No. 1 white, 10½@11; No. 2 white, 10@10½; dark to amber, 7@9; extracted white, 4½@5½; amber, 4½@4¾; dark, 3½@4; beeswax lower, 24½@25. The hot weather restricts demand. No movement.

WESTCOTT COMMISSION CO., 213 Market St., St. Louis, Mo.

July 8.

ALBANY.—Honey.—Fancy white, 11@12; No. 1 white, 9@10; fancy dark, 6@7; No. 1 dark, 5@6; extracted white, 5; dark, 4. There is but a small amount of comb honey on our market, and that is of an inferior quality. We do not look for any new before next month. We have quite a stock of extracted, both light and dark, on hand.

CHAS. MCCULLOCH & Co., Albany, N. Y.

July 2.

PHILADELPHIA.—Honey.—Old comb honey mostly cleaned up. Odds and ends sold at any reasonable offer. Very little new in yet—not enough to establish a price, and will be no call till September. Extracted dark, 3½@4; amber, 4@4½; light, 5@5½. Prices will rule low; big crop everywhere. Beeswax, 25.

W. M. A. SELSER, 10 Vine St., Philadelphia, Pa.

July 10.

MINNEAPOLIS.—Honey.—The demand for comb honey is very light, and prices more or less nominal. We quote choice white clover at 12@14; light amb r, 8@10. Extracted in fair demand, and prices lower. Choice white clover, 5½@6; choice amber, 4½@5.

S. H. HALL & Co., Minneapolis, Minn.

July 10.

DETROIT.—Honey.—New comb honey is being offered, and brings 10@11; old honey, 7@10; extracted, 4@6. Beeswax, 25@26.

M. H. HUNT, Bell Branch, Mich.

July 7.

NEW YORK.—Honey.—No comb honey on our market. Some demand for white comb at 10@11. Market on extracted rather weak. Demand slow of late, and arrivals plenty. Southern, average common grade, 50¢ per gallon; better grades, 55¢@60¢ per gallon; Caliform ia, light amber, 4½@4¾¢ per lb.; white, 5@5½. Beeswax remains steady at 26@27.

HILDRETH BROS. & SEIGELKEN, 120-122 W. Broadway, New York.

July 7.

FOR SALE.—Fancy extracted in 60-lb. cans, and fancy comb (Danz) extracted mangrove honey in 30-lb. cases. Cash offers wanted, f. o. b. here.

H. PRICE WILLIAMS, Miami, Florida.

Honey Leaflet

Dr. C. C. Miller.

Why honey is more wholesome than cane sugar.

Honey as an article of diet; honey cooking recipes.

This leaflet is written for the benefit of consumers, and is put out at an extremely low price so that honey producers may distribute them free to their customers. Prices: 10, 5¢; 100, 20¢; 500, 75¢; all postpaid; 1000, 75¢, carriage extra.

The A. I. Root Co., Medina, O.

ORDERS filled by return mail for the choicest untested Italian queens at 60¢ each. Can furnish 1, 2, and 3 frame nuclei. A. I. ROOT COMPANY'S SUPPLIES. Send for 36 page catalog. JOHN NEBEL & SON, High Hill, Mo.

# What Has Been Told Lately

In the *Bee-keepers' Review*? did you ask? Well, in the Jan. issue Mr. Aspinwall explained a simple plan whereby the mating of queens at the home yard may be secured with almost *absolute certainty*. R. L. Taylor, in the February issue, describes an experiment made to determine if honey stored in the super of a foul-broody colony was infected with the germs of foul brood. In the March number, Isaac Lundy told "How to Get Drawn Combs right in the Sections, and Secure Comb Honey at the same Time." In the April issue, R. L. Taylor tells at what a high temperature he kept his bee-cellar last winter, and the results. The June issue contains a long article from Mr. Lundy, explaining his methods, and giving the details of a plan whereby he secures drawn combs during the white-honey harvest. Of course, there are other articles, editorial comments, extracts, notes from foreign bee-journals, Hasty's "View of Current Bee Literature," etc.

The *Review* is \$1.00 a year; but for the sake of getting new subscribers I am offering it for 1897, and 1000 first-class sections, for only \$2.50; or the *Review* and a Bingham Conqueror smoker for \$1.75; or the *Review* and a fine tested Italian queen for only \$1.50.

W. Z. HUTCHINSON, Flint, Mich.

## Three Car Loads.

My third car of goods from The A. I. Root Co. has arrived, and I am prepared to fill orders for regular goods by next train at Root's prices. Send for my 36-page catalog, or send me a list of goods wanted and I will make you bottom prices.

GEO. E. HILTON,  
Fremont, Mich.

Philadelphia Office of

THE A. I. ROOT CO.,

10 Vine St., Philadelphia, Penn.

Now is the time to order

Shipping - cases, Winter Cases,  
Chaff Division-boards, etc., etc.

Order from catalog; prices are same  
as from factory.

**Italian Queens**, either golden beauties or 3-banded imported stock. Tested, 90c each; untested, 55c each; 6 for \$3.00. One sample queen to new customer, 50c; breeders, \$2.00 to \$3.50 each. P. O. M. O. office, Lavaca. E. A. SEELEY, Bloomer, Ark.

## Root's Goods at Root's Factory Prices

At Des Moines, Iowa.

Immense stock of the latest 1897 goods now on hand, and more to follow.

Thousands of Hives and Millions of Sections are our record, and other goods in proportion. We are sure to please you if the best goods at bottom prices and good service will do it. Eleventh annual catalog FREE. Address

JOS. NYSEWANDER, Des Moines, Iowa.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4-inch Smoke Engine too large. January 27, 1897.

Truly, W. H. EAGERTY, Cuba, Kansas.

T. F. BINGHAM, Farwell, Michigan.

## A Penny Saved is a Penny Earned.

Yes, it's better than that, for the saved penny you don't have to earn twice. Well, the *Weekly American Bee Journal* will help you save your pennies. It is a real money-saver to the bee-keeper who will read and practice its teaching. The regular price is \$1.00 a year, or only about two cents per copy. But in order that new readers may give it a trial we will send it for only 50 cents from the time we receive your subscription to the end of 1897. Now, the sooner you send the half dollar, the more copies you will receive. Send 1c stamps if more convenient. Sample copy free.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

## STRAY STRAWS

FROM DR. C. C. MILLER.

PLEASE, Messrs. A. I. Root Co., don't bring a live *Apis dorsata* into this country until you know they can be domesticated. [You need have no fears on that score.—Ed.]

MANY REPORT honey coming in well, especially in white-clover regions, but figures in Honey Column are not very encouraging. Still, I'd rather have big crop with little price than little crop with big price.

BEE WORK crowds so that I had to get up at 3 this morning to finish these Straws. [I have thought, doctor, that you seemed to be quite busy; but you are rather reticent as to whether or not you are getting honey. I suspect you are.—Ed.]

IN GRADING honey, is there any need of demanding that both sides of a section be immaculately white in order to take highest grading? When on the table, if the upper side is white, does it matter if the other side be darkened?

AFTER SWARMS, Isaac Lundy says, in *Review*, he prevents by putting a cone escape on the mother colony. Why not? If no bees are allowed to enter the hive about the time the young queen emerges, but are compelled by the escape to join the swarm, the destruction of the other queens may be relied upon.

E. H. SCHAEFFLE finds that bottom starters have a bad habit of curling over—p. 486. If top and bottom starter are only  $\frac{1}{4}$  inch apart, the bees fasten them together the first thing, and that prevents curling. [Bottom starters had a fashion of curling over for us last year. It is possible we made them too wide. Ours were about  $\frac{1}{2}$  inch.—Ed.]

PROBABLY it will be the best way for foundation-makers to paper foundation unless ordered otherwise, but I think it will be economy, for us Northerners at least, to order all founda-

tion unpapered. [If our customers will specify whether they want their foundation papered or unpapered we shall be very glad to comply with their wishes, whichever way they may choose.—Ed.]

IF THE FIGURES on p. 487 are correct, it's necessary to make our bees' tongues only one-ninth longer to bring them up to *dorsata*. It ought not to be so very hard to accomplish that, seeing there is considerable difference in different colonies. [It only goes to show how ridiculous are the claims that *Apis dorsata* would have tongues so much longer that they could reach into flora that our own bees could not.—Ed.]

NOW WE HAVE the Medina mark—1000 sections folded in 40 minutes, and 1000 starters put in in 2 hours. Common people who reach the half of that may be well satisfied. One thing that helps the starter business in Medina is that small starters are used and the sections thrown into a basket. With full starters they should be placed directly in the supers—don't know but they ought to anyway—and that takes more time.

E. E. HASTY ought to be drummed out of the regiment—always raising troublesome questions. In *Review* he goes on after this fashion: "Is it not usually the case with any sample of honey, that its flavor is the joint result of two flavors—one secreted by the plant and one contributed by the bee? Is it not possible that most of the flavoring contributed by the plant is taken out of the nectar the day it is brought in, and stored in the bodies of the bees, and restored later on in a somewhat altered and less volatile form?"

L. A. ASPINWALL thinks the chief cause of swarming an abundance of bees of all ages, with the following as adjunct factors: "Temperature, ventilation, drones, pollen, honey, the influence of a honey-yield extending into a failure of the honey sources, the swarming-impulse, the inherent tendency, and, lastly, that under the circumstances of supersedure."—*Review*. [The sentence containing the "ad-

unct factors" is, it seems to me, a little involved—at least I do not clearly understand what is meant, although I think he is trying to tell us what we already knew.—Ed.]

A DISCOVERY is reported in the *Australian Bee Bulletin*, in prevention of swarming. Just turn the hive upside down once in nine days, and the bees will destroy the queen-cells. The *Bulletin* may save its readers much disappointment by saying that the same discovery was made in this country several years ago, and, after extensive trial, it proved a failure. Bees don't always destroy the cells, and, besides, they often swarm with only eggs in queen-cells.

I MUST PUT IN just a word for Punics. You say, Mr. Editor, they have hardly a redeeming quality; but from my limited experience the one redeeming quality is an important one. They're great workers; and if I were working for extracted honey I shouldn't object to some of the blood in my apiary. But they couldn't be tolerated for comb honey on account of filling the cells so full as to make the combs look watery. [I said, doctor, that they had hardly a redeeming quality. They may be a little better than the average Italians or hybrids, for extracted honey, but I doubt very much whether they are. Their bad qualities put them considerably behind in the race with other bees.—Ed.]

IT IS TRUE, Mr. Editor, as you say, that "the general run of customers do not take kindly to candied honey." But that leaves it still an open question whether it might not be best for producer and consumer that they should be educated to it. Muth's experience is not on paper. Better sell granulated honey to a man taught what to do with it than to sell liquid honey to a man who doesn't know what to do with it when it candies on his hands. [There may be some truth in what you say; but it is uphill work to educate the public. Most of the beekeepers and dealers with whom I am acquainted seem to have come to the conclusion that it is better to keep honey liquid as long as possible; and when it candies, exchange it for liquid.—Ed.]

DAVID N. RITCHEY feels sure *Apis dorsata* can be domesticated, and that they should at once be imported to test the matter of their acclimatization. If their domestication is established, no one will object to their introduction. What I object to is their introduction before we know they can be domesticated. [It looks to me, in view of what was published on pages 487, 488, from the pens of those who have been in the native homes of the *dorsata*, that it is exceedingly doubtful whether they could ever be domesticated. But, nevertheless, GLEANINGS desires Mr. Rambo to give the matter a test when he returns to his missionary labors.

In view of this, speculation from those who are not personally acquainted with *A. dorsata* in their native climate is worse than useless.—Ed.]

"BEE-KEEPERS," says Editor Hutchinson, "have one bad habit. If they agree with their editor they write and pat him on the back. If they don't agree with him they keep still. They ought to write to him just the same, if they don't agree with him." All of which is more or less true. But, say, W. Z., some editors have a bad habit. They'll publish only what's written them on *their* side. [Yes, both subscribers and editors are quite inclined to believe the way they *want* to believe. The subscriber is too much inclined to write to the editor agreeing with him; and the naughty editor is very much inclined to publish that side of a question which accords with his views, or, perhaps, more exactly, his *prejudice*. I believe I am as human as anybody else; but I have often tried, to give greater emphasis to the side that is opposed to my own opinions.—Ed.]

THE *American Bee Journal* is now faithfully working on the report of the St. Joe convention that got water-logged more than two years ago. The last five numbers have been occupied with Frank Benton's essay on honey-plants, which has grown so much in two years that it now fills about six pages of the *Old Reliable*. It is, perhaps, the fullest thing of the kind ever written. [Yes, it is no doubt the fullest; but very often I have seen a long list of honey-plants, all of which have practically no bearing at all on the honey market, and the reader is led to believe that they all yield honey to a considerable extent. The honey-plants of importance in this country can almost be counted upon the fingers on one hand. It seemed to me, as I glanced over Mr. Benton's essay, that he was giving the unimportant ones almost as much prominence as the others.—Ed.]

By R. C. Atkin.

ALFALFA HONEY; ITS GRANULATING QUALITIES; A REPLY TO E. T. ABBOTT AND F. L. THOMPSON.

Mr. Editor:—I had not intended writing any thing more in regard to the granulation of alfalfa honey; but it seems to me that, while Messrs. Abbott and Thompson are thumping me, may be I had better hit back a little.

Now turn again to page 115 and see what I

said about it: "Now, while the body, color, and flavor are excellent, there is one feature that is against it; and that is its tendency to granulate. Alfalfa comb honey, as a rule, will not keep over winter without granulating to some extent, both in brood combs and in sections.

I suppose Mr. Abbott's article was intended to show that I misrepresented, more or less, alfalfa honey. That he utterly failed in this, I shall prove by his own words. The first sentence in the third paragraph of Mr. Abbott's article, page 321, admits every thing I said, for it reads: "I know that, generally speaking, alfalfa honey granulates very quickly; but I am inclined to think that this is due more to the way the honey is handled than to any inherent tendency in the nectar of the alfalfa-plant."

I said it has a "tendency to granulate," referring to *alfalfa honey*, then qualified as to *comb honey*, by saying, "as a rule, will not keep over winter without granulating to some extent." Is not that both "generally speaking," and qualifiedly too? The italics I have supplied here. Further, Mr. A. did not know what he was talking about when he intimates that it is "the way the honey is handled" that causes its granulation. More light on this farther along.

Let me quote Mr. Abbott again: "I am also of the opinion that the tendency to granulate is due to a lack of 'body.'" Throughout the article he intimates that producers of alfalfa take unripe honey. In closing his third paragraph he says, "I incline to the opinion that the great tendency to granulate shown by extracted alfalfa honey is due to improper manipulation, and I would advise the other extracted-honey producers of Colorado to take a few lessons from Mr. Foster, and to work for quality rather than quantity, and then they will not say that all alfalfa honey will granulate in a short time. I know from experience that it will not."

Now, Mr. Abbott, just tell me who said, and where, that *all* alfalfa honey granulates, even in a *long* time? I wonder, too, if Mr. Foster's letter, which I quote hereinafter, will not throw some light on your "experience" whereby you "know" about these matters. Friend Abbott, before I leave you just let me ask you how many tons of alfalfa honey have you handled? what per cent did not granulate? was it *heated* after being extracted?

Mr. F. L. Thompson asks a few questions, pages 321, 322, which I will answer. Referring to granulation he asks: "Is it not true that there is a marked difference between early and late honey in this respect?" Yes, there is a difference. The early honey seems thicker, and does not granulate nearly so much in the comb, but does granulate when extracted. My experience with comb (section), kept over win-

ter, is that a small per cent will granulate. I have never kept more than a small amount, always dry but not warm.

The rest of your questions I can not fully answer; but in a general way I will say that my *opinion* is that straight alfalfa comb, kept as 99 out of every 100 bee-keepers or merchants would keep it, would granulate from 5 to 20 per cent. The cells would not become solid, but be a mixture of granules and liquid. My extracted always granulates, and so does all alfalfa extracted I have ever seen. One year there was a flow from red and alsike clover right at the start, and this honey did not granulate so solid as that a few days later, after the clover was cut down.

In order to be more certain, and that others besides myself might testify, I have sent out the following list of questions to a number of apiarists:

1. How quickly, and what per cent of your extracted alfalfa honey granulates?
2. What per cent of your alfalfa comb honey granulates if kept over winter?
3. Do the winter stores in the brood-combs granulate, and to what extent?
4. In the matter of granulation, how does alfalfa compare with other honeys?

Mr. Oliver Foster, Las Animas, Colo., replied somewhat in detail. He has given me his consent to use any part of his letter in print that I may wish, so I am going to use it all. I know that friend Abbott will want a lesson or two from it. Here is his letter:

In reply to your questions of the 22d, I have read with interest your article on the granulation of alfalfa honey, and also that of my friend Abbott. I think you are both in a measure right. My alfalfa honey, both comb and extracted, does, as a rule, granulate, but it does not seem to be confined to rule. Comb honey does not granulate until late in the winter, and then it does not get very hard unless honey has been previously extracted from the comb. I do not think my extracted alfalfa honey granulates sooner than basswood, clover, and heartsease of Iowa. If it did, I should not consider that an objection unless it also granulated quickly after melting, which it does not, if properly melted and if it is well ripened. Alfalfa honey may be very thick and not ripe. I think it can not be produced in perfect quality by ordinary methods. We use 40 to 45 lb. combs to the colony, and then heat the honey before and after extracting to get it out, and through a fine muslin strainer. After storing in 60-lb. cans we let it granulate as hard and as soon as it pleases. Just before shipping, I take 24 hours to melt honey in a water bath. It takes 24 hours to melt honey properly. We leave the cap screwed on tight while melting.

In answer to your questions: 1. Extracted alfalfa usually granulates at the approach of cool or cold weather; the time depends on season of extracting. Perhaps one to three per cent will not granulate at all; that is, of 100 lb. cans filled from the same lot, a few never granulate, whether having been heated or not. 2. I think about all alfalfa comb honey will granulate if kept over winter, unless it is kept in a very warm place—usually by Jan. 1.

3. The winter stores in brood-combs granulated last winter and three years ago to an extent affecting seriously the prosperity of many colonies; but I think it was owing to other than alfalfa honey.

4. In the matter of candying, alfalfa honey compares favorably with other honeys, except in the case of comb honey.

OLIVER FOSTER.

Mr. D. S. Jenkins, also of Las Animas, re-

plied, and I give his replies in abbreviated form, quotation-marks showing his own language:

1. "Comb honey (alfalfa), sealed before about the 4th of July, will keep over winter if kept in a warm place; but the same honey, if extracted, will granulate if not kept at a temperature of 145 to 150 degrees for about 24 hours. If the heat is applied as mentioned it will pass the winter and not granulate; but to start with the honey must be *well ripened*; otherwise it will granulate."

"I have samples of alfalfa extracted honey three years old that were heated, the samples being taken at 145 degrees, and each additional 5 degrees thereafter up to 190. The 145 to 165 granulated in about 68 days." The greater the degree of heat applied, the slower to granulate. "The 190 sample is not fully granulated yet. If Mr. Thompson will take a section of his fine comb honey that will not granulate through the winter, and pick the cappings off some of the cells and stir it with a pin, he will find that the cells so treated will granulate while the others will not."

2. "June comb honey, if kept in a warm room, will keep over winter; but if exposed to the cold I expect all of it to partly granulate."

3. "About 50 per cent."

4. Could not answer, experience being limited to alfalfa and cleome. "Some seasons worse than others." Gathered in damp cool weather it granulates worse than if gathered in hot dry weather.

Mr. W. L. Porter, North Denver, answered, and I give the gist of his replies:

1. "In 30 days, and sometimes sooner; cleome more slowly."

2. Had not observed closely, "but think 10 per cent on an average."

3. This question he did not answer in a general way, but says "winter stores are all granulated hard except in localities where cleome is abundant. I have cleome gathered two years ago in the brood-combs that is still liquid."

Mr. Porter has several apiaries. In regard to tendency to granulate, he puts sweet clover first, alfalfa second, and cleome third.

In 1889 I handled, from three apiaries, 12 tons of honey, principally alfalfa. In 1890 the crop was 12 tons. One year since, I produced 9 tons. The remaining years since 1890 have had from two to five tons each year, a total of over 40 tons in seven years, and about half and half comb and extracted. The comb has, all but a few cases, been marketed early, so I do not know how it kept. Of the extracted, about 99 per cent granulated, and nearly all inside of 30 days.

As to the body of this honey, it could not be extracted except warm from the hives, or by the application of heat. Many a time I have had to stop extracting because it would not

pass through a 1¼-inch hole as fast as extracted in a two-frame machine, but filled up the reel dragged in the honey. Mr. Foster says, "Alfalfa honey may be very thick and not ripe. I think it can not be produced in perfect quality by ordinary methods." I know no reason why not ripe if thick. I know the *flavor* of all honeys changes somewhat as they get older, but I understand the term "ripe" to apply to consistency, in its general meaning as applied to honey. I do not consider *any* honey of "perfect quality" produced by ordinary methods. An apiarist of large experience in the east has often told me that, in Colorado's dry climate, it was altogether unnecessary to wait for the honey to be sealed. I want mine sealed, or largely so.

I have before me samples of honey. First is one of white clover 13 years old. It was never heated, but granulated solid, and stayed so for two or three years, then gradually liquefied until about one-half liquid, where it remains unchanged. It has become about as dark as light sorghum molasses.

Next is a sample of alfalfa eight years old. This was solid for over a year, then became about one-fourth liquid, and remains so. Its liquid portion has become slightly amber in color. It was never heated.

Next is alfalfa five years old, once heated to liquefy. I do not know the degree of heat, but just enough to melt it. This soon granulated again, and is now about five-sixths granules.

I also have a sample three years old, never heated, but put into glass when extracted, and it is apparently *all* solid, and has remained so. This has not even been in a warm room. The first and second samples mentioned were at times in a warm place—one near a stove, the other in the gable of the honey-house. The heat helped to partially liquefy.

I have also a sample three years old, once liquefied, that has gradually granulated, till now it is about one-half to two-thirds granules. The last sample I have is two years old, liquefied by heat, and is now about nine-tenths liquid.

One thing is very noticeable in these samples: The honey in those to which heat was applied, when it does again become solid, is more strictly granules mixed with the liquid portion; but that which was never heated forms a body almost like lard, and quite firm.

I have liquefied tons of honey, but never tested the degree of heat necessary. This is one of the things I have planned to do, but as yet have never found time. I am scarcely an able-bodied man, but must earn my living, so I find it hard to do all the experimental work I wish. Time and money, properly applied, would soon settle many disputed points. Observing, however, as I go along, I have come to the conclusion that a low degree of heat, say but little above 100 F., if applied for several

days and continuously till the whole mass of honey is thoroughly heated and liquid, will do the work all right without injuring the color or flavor. My stove, where the heat is irregular (in water bath), I have never succeeded in liquefying so it would long stay liquid, unless it became so hot as to injure color and flavor, unless I continued the heat for 24 to 48 hours.

But I am drifting from my topic, and must return and bring this to a close. I must admit that my experience with other honeys than alfalfa is quite limited. I have produced some little basswood, a very little mustard, and considerable white-clover, heartsease, and Spanish-needle. I never carried a stock of comb very long, and do not remember to have had any of these granulate; but the extracted did granulate more or less, though none of it so quickly as does the honey here.

My sources here are alfalfa for 75 to 90 per cent, the rest being about equally divided between sweet clover and cleome. I did have some red clover, but it is about all gone now.

I think the time is very near when extracted honey will be marketed granulated, such as will granulate; and if it does become solid it will be no detriment—rather a help. If it is true that other honeys in the comb will granulate as freely as alfalfa, then the latter is sure to take the lead, for its color and flavor will find it a market. I once sent a sample of alfalfa extracted to a Chicago firm who are very extensive honey-dealers, and they said it was "without question the finest sample of extracted they had ever seen." This had been melted before sending, but was of the honey friend Abbott wants improved upon.

Must Colorado apiarists use exceptional methods that are not required by Missouri producers? No, friend Abbott; if we must use other than "ordinary methods," as Mr. Foster does, to get honey that will not granulate, it but proves my statements.

Usually the first honey gathered—that supposed to have the least tendency to granulate—is stored in the brood combs. How comes it, then, that so much of it granulates? The first stored in brood-combs is the last to be used from them, yet we find a large per cent of this granulated.

Loveland, Colo.

### THE ADVANTAGE OF NARROW BOTTOM-BARS.

OSBORN'S COMB-CARRYING CART—OBJECTIONS TO IT.

By O. O. Poppleton.

Nearly a year ago, Dr. Miller, in one of his Straws, asked any bee-keeper, who preferred and used narrow bottom-bars, to give the reasons for his preference. I intended to answer at the time, but it was overlooked.

Unless combs are entirely built down on to the bottom-bars, spaces will be left between the comb and bottom-bars. These spaces above wide bottom-bars are much more trouble to brush bees out of than when narrow bars are used. This, of course, applies to the production of extracted honey much more than when working for comb honey, and to me it is a very important point.

Theoretically, end-bars of frames should always hang in a hive a bee-space away from the sides of the hive, and never be fastened by the bees to the sides; but practically I have never seen that condition. Frames will sometimes get a little out of true; the sides of the hive may get a trifle warped, or something else not just right will diminish this bee space, and the bees will fasten frame and hive together with a mass of propolis. This makes extra work, costs time, is a draft on one's stock of patience, and a general nuisance.

There are several ways in use for remedying this, but I do it with my narrow bottom-bars, which are about  $\frac{1}{16}$  x  $\frac{3}{8}$  inch, a trifle longer than the made-up frame is long, and ends sharpened. These are not nailed on the bottom of the end-bars, but inserted in a kerf sawed in the lower ends of the end-bars, and allowed to project enough beyond the bars to keep them a proper distance from the sides of the hive. The use of these projecting bottom-bars enables one to handle frames more rapidly than otherwise, as they can be taken hold of with one hand, near the middle of the frame, and lifted out quickly and carelessly, with no danger of crushing bees between the end of the frame and the hive. Mr. John Bird, of Bradford, Ia., one of the most experienced and successful bee-keepers in the Northwest, told me last fall that he considered the projecting bottom-bars as one of the most indispensable features of good frames, because of the aid they give to rapid handling. He uses the Langstroth frame. He also told me that he values the narrow bottom-bars for another reason. Nearly every one who has wintered bees in the North knows how the accumulation of dead bees on or near the bottom of hives during long confinement in a cellar causes moldy combs. This can be mostly remedied by occasionally dragging the dead bees out with a bent wire—that is, if the wide bottom-bars of frames don't catch and hold the bees off the bottom-board. Narrow bottom-bars, of course, allow the dead bees to collect where the apiarist can easily prevent any undue accumulation.

On p. 336 of GLEANINGS for May 1st you picture a wheelbarrow for carrying combs of honey, and refer in your footnote to the cart used by Mr. Osborn, in Cuba. I used his cart long enough to learn it had several faults. One was its being so low down that it was very back-aching work to handle combs to and from

steadily all day. Another was that the combs run crosswise instead of from front to rear, and that caused more or less mashing of the combs against each other. Another trouble was the greater difficulty of keeping such a large box covered up from robbers. I prefer two or three smaller comb-boxes, holding the same number of combs in the aggregate, higher up from the ground, and with combs running from front to rear.

Stuart, Fla., June 5.

[Three or four years ago we started making the bottom-bars of all of our frames  $\frac{3}{4}$  square, and personally I was much pleased with the results secured from them in our own apiary; but our customers protested. Finally we compromised by making a bottom-bar  $\frac{3}{8}$  inch wide instead of  $\frac{3}{4}$ , as formerly. The only objection that can be named against the use of narrow bars is that the bees will sometimes build the comb clear past the bar, and attach it to the frame below. This applies only to where the hives are tiered up. Only yesterday (June 25) I was looking at some beautiful solid combs built clear to the bottom-bar. These bars were  $\frac{3}{8}$  inch square; and in only a few cases are the combs built down to the bottom-bars  $\frac{3}{4}$  by  $\frac{3}{4}$  inch. I am half inclined to believe our customers didn't know what they wanted.

The idea of having a bottom-bar project past the end-bars a trifle was used by D. A. Jones away back in 1879 or '80. I know that, at the time I visited him in 1882, he was very enthusiastic over this feature, and wondered why we didn't incorporate it in our apiary. The fact of the matter is, the supply-dealer does not dare to deviate very much from standard accepted lines or he will hear a buzzing, not of bees, but of bee-keepers, around his ears.

Your objections to the Osborn comb cart, I should say, are very well taken. A good cart for carrying combs is yet to be devised. I have thought that a cart might be made having two or three closed compartments, each compartment holding ten or twelve combs, and having lids that will close absolutely bee-tight. This cart should be high enough to prevent back-breaking stooping, and so arranged as to distribute the load on both sides of the axle-tree. After all, I am not sure but a light wheelbarrow, having on it three ordinary bee-tight hives, would be nearly as good. If, instead of the hives, boxes of the same dimensions made of  $\frac{1}{2}$ -inch stuff were used, it would make the load a little lighter.—ED.]

#### LARD-CANS FOR EXTRACTED HONEY, ESPECIALLY FOR THE COLORADO MARKET.

A REGULAR UNIFORM PACKAGE INDORSED; BUT SOLDERED CANS NOT AS DESIRABLE AS THE STANDARD PAILS THAT WILL NEST.

By Mrs. A. J. Barber.

*Editor Gleanings:*—In your footnote to Mr. Aikin's excellent article you ask for the opinions of the brethren on the honey package question. I take the liberty (as ours is an equal-rights State) to give mine. The uniform package and trademark system is, no doubt, a good one, and I hope to see it carried out; but I want to enter a protest against the soldered cans.

To begin with, I do not see the necessity for

sealing at all. Colorado honey granulates so quickly that it is safe for any length of time in tin pails with close-fitting covers. We have sold thousands of pounds of extracted honey in the common lard-pails. The five-pound size holds  $7\frac{1}{2}$  lbs., and the 3-lb. size 5 lbs. Being a standard article, and manufactured by thousands, they come cheap. As they can be nested they take up less room than straight cans, and we get better freight rates on them. The ball or handle makes the pail a more convenient package to handle than a can, and the pail is useful after the honey has been used up. The pails are easier filled and covered than cans that have to be soldered. The pails can be crated as easily as cans. We use 40-lb. apple-boxes. Such a box holds one dozen pails—six of each size. We have used them for two years, and have never had any fault to find with such a crate. It makes a neat package, and holds the pails securely, and is easily handled. Last year we sold several thousand pounds of granulated honey in such pails and crates, and have not had a single complaint, though the honey has been in all the mining towns in this part of the country. I believe it is a mistake to try to keep Colorado honey on the market in liquid form. Any one who knows any thing about this climate knows that honey always granulates quickly here; then why not face the situation squarely, and teach people that granulation is a test of the honey's purity. A neat label on every package, stating the fact, and giving directions for liquefying, will soon do the business.

To sum up: I claim that the pails have these advantages over the soldered cans: They are cheaper, and freight is less, as they come nested. They are much easier and quicker to fill and cover. They are handier for the buyer and seller also, as they have a handle to carry them by. They can be opened for inspection or trial, without injuring or defacing the pail. The vessel is useful after the honey is all used up. You can store a thousand of them in less space than five hundred straight cans would occupy, and you can get them from any wholesale hardware house by simply ordering three and five pound lard-pails instead of having to give a description of cans, and waiting for them to be made.

Now, having presented the case for the lard-pails I should like to hear what the advantages of the straight cans are, if any, over the pails.

Mancos, Col.

[The lard-cans that you recommend have long been used by the Dadants; in fact, that is their standard package for extracted honey when put up in a small way. The fact that these pails will nest together is a big point in their favor; but sometimes the honey will not candy solid. This is especially true of some honeys and some localities; and in some markets partially candied honey will sell at a great discount. Then, again, it is sometimes

desirable to make immediate shipments of extracted honey. If you had an order for a carload of extracted honey put up in lard-cans for immediate delivery, just as the honey came from the hives, it might be a problem as to how you would get this to a distant market without a good deal of leakage. Then, too, a package that is easily opened is liable to be tampered with by naughty boys and freight-handlers *en route*. The standard fruit-can package soldered tight will go safely, whether candied or not. Honey put up in these cans could be shipped immediately. Where honey is put up in nested pails it ought to wait till it is candied before it is ready for market.—Ed.]

### HONEY IN THE DANZENBAKER SECTIONS.

THE OPINION OF THE MAJORITY NOT ALWAYS RIGHT.

By B. F. Ouderdonk.

*Mr. Root:*—The 1000 "Danzy" sections came to hand, and are highly satisfactory; the change in width of bottom and top adding one-eighth will help the appearance of the finished section, and make the weight, when filled, a plump pound. I notice the bees this year draw the combs beyond the wood at the bottom of last year's sections, so the glass presses on the honey. I have taken off three supers of Danzy sections so far, and the lightest weighed  $14\frac{1}{2}$  oz.; heaviest,  $16\frac{1}{4}$  oz.; but the majority weigh plump 15 oz. I sell all I can produce, at 20 cts. each; the  $4\frac{1}{2} \times 1\frac{1}{2}$  at 15 cts. If you look in the

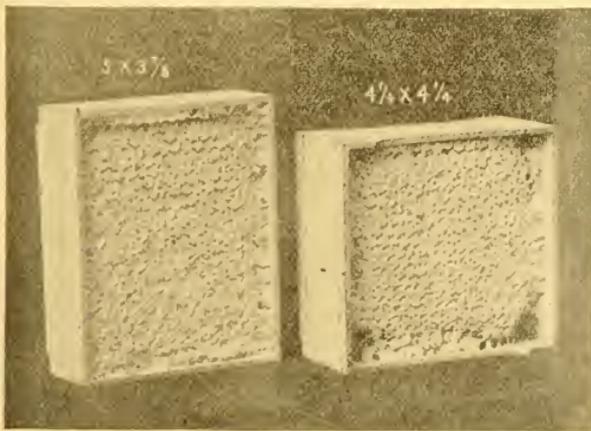

meaning what is arbitrarily styled the standard section.

I know little about bee-keeping. I am an amateur of two years' practice, commencing in May, 1895, with three colonies, and, buying one nucleus of Carniolans, have increased to 30 colonies at this date; but when I see the Danzenbaker section filled solid to the wood all round—sides, top, and bottom, while my  $4\frac{1}{2}$  sections have passageways through each lower corner, and even the whole bottom open, I feel a Christian regret for the experts, and rather hope to die an amateur.

By the way, I have always looked upon the tin strips on super bottoms, to hold the sections, as an abomination, and have found a way out. I drive carpet-staples  $\frac{3}{8}$  inch into the end-bars of holders, and hang them in the rabbets, using a device like the "dividers" one of our friends writes about on one side, and  $\frac{3}{4}$ -inch strips on the other. The bee-space all around seems a great comfort to the bees.

Mountain View, N. J., June 29.

[We have before had reports from those who have been using the  $4 \times 5$  sections and the  $4\frac{1}{2}$ . The former, in nearly every case, I think, sold for a higher price in the open market. Whether this difference was owing to this fact that the  $4 \times 5$  looked larger by *contrast* than the square ones and therefore brought more money, or whether the oblong shape is really more desirable even when alone, is hard to say. If the  $4 \times 5$  sells at a higher price because of the more pleasing contrast, then when the square sections are crowded out of the market I am of the opinion that the  $4 \times 5$  would seek the same level in price as the  $4\frac{1}{2}$ . In the cut both sections weigh the same. Which one *looks* the bigger?—Ed.]

*American Bee Journal*, p. 378, under "Question-box," Prov. 11: 14, you will wonder how scripture texts can be twisted to suit the views of fossils. Captain Hetherington ordered 50,000 cartons for tall sections from one house in New York, and yet out of 22 experts only three in the aforesaid Question-box favor tall sections; and one of them, Rev. M. Mahin, says: "But I am not sure but that, if I used another style of hive, I should prefer  $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ ," doubtless

### HONEY AS FOOD.

ITS VALUE MUST BE MORE GENERALLY MADE KNOWN.

By F. A. Snell.

There is no doubt as to the great value of honey as food and the purest sweet known. Honey strengthens and invigorates the whole system, and acts as a regulator. Honey is easily digested and assimilated, and can be eaten by people suffering from some diseases where sugar would not be allowed by a well-read physician to a patient under his care, so afflicted. For throat, lung, or bronchial trouble it is highly beneficial, and has prolonged the life of many so suffering who have used it. In case of sore throat I have found half a teaspoonful of honey, taken at intervals of fifteen or twenty minutes, very soothing.

Its healing properties are great. Honey for ages was the only sweet used; and its usefulness was well realized. At present its use has been too much superseded by that of sugar and the vile glucose syrups sold at the groceries, and bought by people who think it cheap, when in fact it is dear if health is at all considered. The people must be educated, and bee-keepers have this work to do if it is done; and it must be, as with our increase in production we as apiarists will see lower prices than we have yet, and we all know now, counting the seasons as they come, that it is hard work to make ends meet at the end of the year.

In looking back over past years I can not but think of former prices and those prevailing at present. Comb honey I readily sold at 25 cents per pound in 25-pound boxes; later, in two-pound sections, 20 cents. These prices were for 100 lbs. or over. Our first extracted honey sold at wholesale at 20, 18, and 15 cts. per lb.; and later it has been going lower and lower. Now, what can we do to help ourselves? I think we must all work to increase the consumption of our honey, and unite as one man in a noble effort to stop the infamous adulteration of it, and all enemies who rob us of our legitimate and deserved rights should be thoroughly dealt with.

I have been among bees since I can first remember, and personally engaged in the bee business 39 years, and I have not in the past known of a time when energy, push, and united effort were so much needed as now—energy in educating the people; push, to sell our honey for the best price possible under present conditions; united effort in bringing adulterators and thieving commission firms to justice. In fact, our whole business of the disposal of our honey in distant markets needs systematizing—not in one section, but over the whole country. More money has been lost by bee-keepers through commission frauds during the past year than ever before. Bee-keepers, many of them, have shown lack of judgment in shipping to unknown parties, or those condemned by some of our bee-journals. I too have been caught by a few of them, and lost over \$150, but not for the few years just past.

There is no lack of work for us to do, and we should act for our just rights and best interests as a band of brothers.

Milledgeville, Ill.

[The way to educate the masses as to the value of honey as a food and medicine is to supply your customers with honey-leaflets. They should be distributed freely, and along with them should be a circular or card, to the effect that you or some local grocer has the honey for sale. And, by the way, I would see that the grocers are all supplied with honey-leaflets to distribute to their customers. Instruct them to wrap a leaflet in every package of honey that they put up; and if they read the leaflet, in all probability they will want to buy more.—Ed.]

## THE HOUSE APIARY.

ANOTHER HOUSE-APIARY ON THE PLAN OF THAT USED BY F. A. SALISBURY.

By Dr. J. Q. Mulford.

After reading friend Salisbury's article, page 662, 1895, I immediately contracted the house-apiary fever; but the bees had done so poorly for the two previous seasons that I did not feel like adding on the extra expense. In riding by the Shakers, a sect that live some two miles west, I noticed an old bee-house in which I had done some work in transferring some two years before, and I remember of thinking at the time how foolish in them to keep bees in a house. I was over the fence in a jiffy, and the first thing that attracted my attention was the entrance of those old box hives painted different colors, *a la* Salisbury. Instantly the thought came, "If I had been observant when I was working there, instead of feeling in a ridiculing mood, I might have been the first to tell the bee-keeping fraternity that bees *do* distinguish color.

I at once made some inquiry concerning the bee-keeper, but was informed that some ten years had elapsed since he had been heard of; but the house had been built 20 years before on the same plan as friend Salisbury's, excepting it is not quite so high, and is only 8 feet wide and 30 feet long. I hope no one will accuse me of trying to rob friend S. of the priority of making the house-apiary a success. I am only anxious to show that there is nothing new in the plan.

I hunted up the old doctor who had charge of affairs; and as he wanted strawberry-plants as much as I needed the bee-house, we soon made a trade. I put the house on trucks, and moved it home. The first question that troubled me was, which way to set it—east and west or north and south. After puzzling over the question for some time I decided on northwest and southeast. The next question that troubled me was, how to get the bees into the house. I left them on their summer stands until they had been confined there some three weeks by a cold spell, then moved them in. I am sure quite a number were lost during the first flight; but after that they seemed to get their hives all right. I am highly pleased with the house, and find the feeding-arrangement one of the handiest I have ever seen.

For spring I like best to take the can of syrup and walk along and pour the grooves full. You will be surprised at the amount those grooves will hold.

I am quite sure that a ventilated bottom is as great an invention as the feeder. I did not get all the new bottoms on when I moved the bees in; and during one of our very warm days I noticed the bees of one colony were hanging around the front of the hive, and were fanning

as though they were rather uncomfortable. The next morning I put a ventilated bottom under them, and they have been comfortable ever since. Friend S. writes me that he leaves the same bottoms on during summer and winter.

Now I suppose every one who has bees thinks he must have a house for them; and as there has been so much said in its praise he thinks there is no chance of there being any objections; but I find there is one, and a very serious one too.

Often, in the early spring, the sun shines brightly in the morning, and gives promise of being a beautiful day. The bees sally forth. Some return heavy laden, miss the entrance, and drop to the ground. Those on the east side soon rest, and, taking wing, enter the hive; those on the west side at once become chilled, and, if the day should happen to turn cloudy, they are lost. Those on the east, after 4 P. M. encounter the same difficulty; and if they are not helped into the hives they will surely perish. I have picked up a pint of these bees at a time, and poured them into the first hive I came to, hoping in that way to save them.

A house running east and west would be very objectionable on account of the sun never reaching the north side. The best plan would be a house facing southwest, and bees all on one side.

I am highly pleased with my house, and would not go back to the old way of having them scattered all over the yard, under any consideration. While working with them this morning a shower came up; but I continued the work just as well as if it had not been raining. How often, under just such circumstances, do I remember of hastily scrambling my tools together in order to seek shelter!

As to wintering, I am sure the house will be ahead of leaving out of doors. I lost 10 colonies out of 60; but that was due to my starving them by feeding them candy made after the instructions given in the A B C and GLEANINGS. I have succeeded in studying out a plan that is a success, and will report at some future time.

I am using the poultry-wire staples for end-spacers on my frames, and think very well of them at present. I get them at the hardware store for 10 cts. per lb.

Lebanon, Ohio.

[However near the house-aplary you now have (and which was built twenty years ago) may be like the one now used by friend Salisbury, I am sure he was entirely original in the planning of the general design of the one which he has. It only goes to show that the old Shaker and Mr. Salisbury, realizing some of the defects of the former house-aplaries, set about to remedy them by making one that would not have these faults; and that their minds ran in the same channel is nothing very significant, as many another pair of great minds have done the same thing.]

In view of the fact that our bees at the bass-wood aplary have been tampered with by

thieves, and in view of the further fact that we have no building in which to store tools, we expect this fall to put up a modern house-aplary, *a la* Salisbury, at the basswood yard. The structure will be strongly built, and have a good bar and padlock to secure the door or doors. When I visit Mr. Salisbury this summer I expect to take special note of his house-aplary; and if he knows of any faults, we shall, of course, remedy them, so far as possible, in our new structure.—Ed.]

#### DRONE COMB.

*Question.*—Can you tell me why my bees build so much drone comb? In hiving my swarms I give them one or two combs already built to help them start in their new home, and I find, on opening the hives a few days afterward, that from one-half to two-thirds of the comb they build is of the drone size of cells. Can you tell me how I can prevent this?

*Answer.*—Yes, it is easily told. Put in full frames of nice worker comb, filling the hive full; or fill every frame set in any hive full of foundation. See how easy it is! But I am reminded that you may not want to use foundation, or have not the full worker combs on hand, so I will give a few words on comb-building, in which you may possibly find a solution to your difficulty.

All observing apiarists know that, as the day of swarming draws near, the queen ceases her prolificness, so as to be able to fly and go with the swarm, so that, when the swarming does occur, the old mother-queen is scarcely larger than a virgin queen. Nature has so ordained things for two reasons, the first of which is that the queen may fly; for if a queen is taken from a colony when she is most prolific in eggs she can not fly at all, as she is so heavy with eggs. The second reason is, that the queen need not be inconvenienced with an over-accumulation of eggs before there is time for the bees to construct comb in the new home for her to deposit her eggs in; and so we find that all good queens do not become fully prolific again until about a week has elapsed after the new colony has arrived at its new location.

During this week comb has been built very rapidly, especially if honey is coming in plentifully from the fields, while the queen has not been able to keep up with the workers; the result of which is that the bees commence to build store comb, which is always of the drone size of cells. This comb is mainly filled with honey the first season (although in many cases some drone brood is found if the bees feel disposed to think of swarming again, or feel disposed to supersede their queen, or the honey-

flow slackens somewhat), the main trouble coming by having this store comb filled with drone brood after the bees have consumed the honey from these combs the next spring. Why I said good laying queens, is because some seem to think that no drone comb is built under any circumstances with newly hived swarms, unless the queen is old or beginning to fail.

Now, if we give a frame of comb or two to a newly hived prime swarm, as our questioner did, we make matters doubly worse, in that we furnish a place for the queen to deposit nearly all the eggs she would naturally lay during the first week after hiving, consequently nearly or all the comb built by the bees during this time will be for store comb, or of the drone size of cell, as the queen had furnished for her all the room in which to lay that she needs.

In the above we have the reason why bees build drone comb for the majority of beekeepers.

Now, how is such a state of affairs to be avoided? The way I manage is to give the colonies which are to build comb a brood-chamber of only about half the size of the one from which the swarm came, this smaller size being made by contracting the chamber of the new hive to the size I wish, by means of dummies or division-boards, and also giving them a part of the section or surplus room at the time of hiving them. Where a queen-excluder is used, some of the sections should have in them partly built combs left over from the previous season, and the others supplied with thin comb foundation. Unless a queen-excluder is used, where no comb or foundation is used in the brood-chamber, the queen may go up and deposit eggs in the drawn comb which is in the sections. Preparing the hive in this way gives the bees plenty of room above to store honey, thus not crowding them in the brood-chamber, so that only comb of the worker size is built below, and that only as fast as the prolificness of the queen demands it. As her ability to lay increases, more comb is built; so that, at the end of the season, we have the hive filled with nice worker comb and plenty of section honey.

By the above plan three important items are secured—lots of section honey, no drone comb, and a hive full of nice straight worker comb; and as these latter will, with careful usage, last nearly a lifetime, it well pays to spend a little time on them while they are being built. I hope those who are troubled with too much drone comb in the body of the hive, and those who do not wish to fill their frames with foundation, will try this plan, on a few colonies at least; for if it works as well with others as it does with me it will be quite a saving to them, both in vexation and in not raising a host of useless drones to eat up the honey which the industrious little workers gather. Of course,

all of the above is applicable to only those swarms which have laying queens with them, and does not apply at all to after-swarms or those having virgin queens. With colonies having virgin queens there seems to be no disposition to build drone comb, unless the swarm should be so large that comb is built two or three combs away from where there is any brood, in which case a little drone comb may be built. Nor is there much drone comb built in the old colony after their young queen gets to laying, because, when an old colony gets such a queen, instinct teaches them that they may expect this queen to meet all requirements of a mother-bee for the rest of the season; while drones are necessary only when a change of mothers is contemplated by the bees. Hence no eggs are deposited in drone comb, even where such is already built in the hive, and much less is comb built for this purpose. Taking advantage of this fact I often manage to get one or two nice perfect worker combs built for future use, while the bees of these colonies are at work vigorously in the sections, by taking one or two full combs of honey from the outside (storing it away for feeding-purposes should any colony lack in the fall or spring), and inserting empty frames in the center of the brood-nest of colonies which have cast a swarm, and now have a young laying queen. These frames are filled, apparently, without the cost of any section honey, while it seems to give great energy to the colony so building comb. I also place on these last-named colonies having young queens, all sections (if I have such) containing drone comb, where they are filled without danger of drone brood in them, while much drone brood in sections often confronts the apiarist if such sections are used over prime swarms where no queen-excluders are used. Before I used this plan, and previously to the advent of thin worker foundation and queen-excluders, I was often vexed upon finding the sections placed upon prime swarms, nearly half filled with drone brood. It is unnecessary to say that thin worker or section foundation, and the queen-excluders, do away with all trouble of brood in the sections.

#### THE DEATH OF VOGEL.

One of Germany's most noted bee-keepers has passed away of late; and since GLEANINGS has not yet mentioned it I take it upon myself to here speak of it.

The *Bienen Zeitung* of April 13 brought the sad news to its readers that its editor, F. W. Vogel, had gone to a better world, his death

having occurred April 12. In Vogel the German bee-keepers (and for that matter the bee-keepers of the world) have lost out of their ranks a man of rare ability. He has been trying with untiring zeal to disclose the mysteries hidden in the bee hive. It seems that, where many others could see nothing, he saw clearly. With the microscope he was simply a genius. In dissecting the most minute insects and their organs he was a master with perhaps few equals. How often have I been astonished and surprised at his accomplishments along this line!

During his life's career honors have been bestowed upon him by crowned heads of Europe, they having repeatedly taken notice of him, decorated him, etc.

He was honorary member of quite a number of bee-keepers' associations and other societies for the promotion of science of his own and foreign countries.

For years he has been the leading spirit in the annual *Wanderversammlung* of Germany's and Austria's bee-keepers. The success of these meetings must be largely attributed to him, to his qualifications as a manager, his fitness in general. No discord ever entered into these meetings.

In the May issue of the *Bienen Zeitung* Dr. Dzierzon and Bergfeld sing the praises of Vogel, give expression to their sorrow, and with that they express what all the bee-keepers of Germany feel.

It seems as though I had lost a long-loved friend. Vogel will always be remembered.

Naples, N. Y., June 10. F. GREINER.

#### THE ROBBER-FLY.

*Editor Gleanings*:—I have the following letter from C. R. Decker, Tipton, Cal.:

*Prof. A. J. Cook*:—Inclosed you will find a bug which I saw catch and kill a bee. Will you please give through *GLEANINGS* the name and habits of this insect?

This insect is not a bug, but a two-winged fly, one of the large robber-flies that are well known as bee-killers throughout the whole country. It is one of the robber-flies, or *Asilidae*. These flies are either long, black insects, with tapering bodies, or else yellow, hairy insects, much resembling bumble-bees. They have a strong beak, and are very ferocious. I have known one to attack a fierce tiger-beetle, subdue it, and carry it off. They are very common in California. I consider these robber-flies as very valuable. They are among the best of our predaceous insects, and without doubt destroy a great many of our insect-enemies. I doubt if in many localities they destroy enough bees to do any very serious mischief, while it would be hard to overestimate the amount of good which they accomplish.

#### CALIFORNIA KINGBIRD.

A few days ago a kingbird was shot at Clare-

mont, which had a number of bees in its stomach. I did not see the bird, but my authority is such that I have no doubt of the fact. I should have been very glad indeed to make an examination, as I should like to determine as to the sting of the bees swallowed—whether the bird destroyed the stings before it swallowed them, or whether the sting was lodged in the bird's throat, or whether it was still in the bee after it entered the stomach. The same party killed a kingbird a few days after, and brought it to me, when I carefully dissected its stomach. I found in the gullet, not yet down to the stomach, a large robber-fly. Thus, if the kingbird does kill the bees it also preys in part upon one of the bee's worst enemies, the robber-fly. The other insects in the stomach of this king-bird (and they were a large number) were all injurious species. I think, then, that we may say of the kingbird as of the robber-flies, that, while they do take some bees, they do far more good than harm. It is often said that the kingbird feeds only on drone bees, and does not take the workers. This is certainly not true. They do sometimes capture and feed upon worker bees.

A. J. COOK.

Claremont, Cal., June 3.

[In large queen-rearing apiaries it is sometimes necessary to shoot the kingbirds. I remember one season we lost a good many young queens. We also noted that the kingbirds were quite numerous about the apiary. We shot them off, and there was less trouble. I do believe, however, that any bird that feeds upon insects (unless it be sparrows) usually does more good than harm and their lives should generally be spared.—Ed.]

#### HONEY FROM POISONOUS SOURCES.

On page 376 you can't imagine why W. C. Myer wants his bees to work on poison oak. If it is the same as poison sumac, and I think it is, I don't think it will harm bees or man to use the honey, as there is plenty of it in the swamps here, and I never heard of any ill effects from it. Poison ivy is an excellent honey-plant here, and bees just swarm on it when in bloom. The honey goes in with clover, and you would never know it was there.

My 96 colonies all wintered out of doors. One was queenless, but I gave it a cell and saved it. Only 4 weak in the lot. I never had my bees in as good shape at this time of year. Bees began to swarm the 10th—earlier than ever before since I kept bees. I have, from 76 hives, extracted 880 lbs. of honey up to date; lots of fruit-bloom honey in hives now.

E. D. HOWELL.

New Hampton, N. Y., May 15.

[Prof. A. J. Cook holds that honey from poisonous plants is not poisonous. Perhaps the honey from poisonous sources, when mixed with the other honey, bears so small a proportion that it is only a "drop in the bucket." Some of the most deadly poisons, when diluted much, are perfectly harmless.—Ed.]

THE ACTUAL RELATIVE PRICES OF BEESWAX  
AND HONEY IN MEXICO AND THE  
UNITED STATES.

There appears in the *American Bee Journal* of April 29 an advertisement for the sale of a home in Mexico. Elsewhere a statement is made to the effect that wax sells at 50 cts. per pound, and extracted honey at 10 to 12 cts., and from fruit alone on this place he should realize \$250 to \$300 this year. Now, don't let any one be misled by such statements, as you well know Mexico deals in depreciated money, and one dollar of our money will buy two of theirs; consequently 50 cents for wax is not as good as 25 cents is in the U. S.; 10 and 12 cents for extracted honey is not as good as 5 and 6 cents in America, because flour, one of the staples, is worth more than double in Mexico what it is in this country; besides, there is no society to speak of but Mexicans, and I know whereof I speak. To any that may be looking for a home in the beautiful land of sunshine, there is lots of room in Southern California, and the finest honey-producing section in the world. I have 55 colonies of bees, and up to this date have extracted two tons of the finest water-white honey I ever saw, and shall, without doubt, take two or three tons more before the flow ceases, which will be about the middle of July, if nothing happens to prevent it. Please bear in mind I had, spring count, only 20 colonies, and bought 12; the rest is increase. M. H. DUNN.

Fullerton, Cal., May 30. \*

IS COMB HONEY REALLY BETTER THAN EX-  
TRACTED? \*

*Dr. C. C. Miller:*—I wish you would write up the reality of a fondness of some people for eating comb honey. It is nice on the table, and looks very tempting. I like comb honey, but get tired of it, and catch myself extracting the honey from the wax, eating the syrup, and leaving the wax on the side of my plate, and I see others at the same game.

Now, what is the reality in this? Do I like it better in the comb, or is it a notion, which seems to be proven by the wax by my plate?

Dadant says, page 430, Langstroth Revised, that people go to a great expense in raising comb honey to enable the owner to eat his honey with the wax, when, as every one well knows, wax is tasteless and indigestible. It sells for more than extracted honey, but that may be owing to scarcity or demand. How is it when they claim to like comb honey better than extracted, and deny they like the wax?

Newell, N. C.

JOSIAH W. HUNTER.

[Dr. Miller replies:]

I think I don't need to do much writing up after what Mr. Hunter has said. I think it is true that a good deal is foolishly said about the delicious flavor of beeswax pure from the bees without any intervention of man. A few days

ago I took a piece of freshly built comb, pure and white (it was drone comb that I had broken out), and no amount of chewing could extract from it the delicious flavor talked about. A pine stick has a good deal more flavor, and perhaps of just as good quality. I think the mistake has been made in some cases by comparing comb honey with extracted. It is probably true that the average sample of comb honey is of better quality than the average sample of extracted—not because the honey in one case is intrinsically better than in the other, but because so much honey is extracted before it is fit. Usually the best honey can be found in the comb; but it isn't the comb that gives the flavor, and I suppose the best sample of comb honey ever produced would be improved for the purpose of taste by having the wax removed. C. C. MILLER.

[In addition to what the doctor has said, and which I indorse, the general public, to a great extent, are suspicious of extracted. No matter how pure and good it is, they are apt to think it is adulterated; but honey in the comb they have confidence in. If we *think* a thing is better it tastes better, no matter whether it really is or not. Mr. Hutchinson has suggested that it is the crushing of the comb with its delicious sweetness that tickles the palate.—Ed.]

THE NEW DRAWN FOUNDATION—A BOON TO  
BEE-KEEPERS.

The samples of deep cell foundation came to hand in good shape. You must understand the mail-bag is thrown from an express train going at the rate of 50 miles an hour by our way station. I expected to see it crushed. I consider it a good test of strength.

Having read the criticisms I was desirous of comparing it with natural drawn comb. I have before me several sections from last season, full sheets and starters, drawn from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch deep; and even where the bees have built natural comb containing the starters two-thirds down, your deep cell excels it in transparency and whiteness. I am satisfied that, if you can make this new improvement a commercial success, it will be a boon to bee-keepers. Please send me samples of deep cell,  $\frac{1}{2}$  in., as I propose to make an experiment, alternating each kind with starters and full sheets in one super.

Bees are in fine shape—brood-frames full of brood and honey, and supers on.

B. F. ONDERDONK.

Mountain View, N. J., May 7.

[We should be glad to have you give us the results of your experience later on.—Ed.]

YELLOW-JESSAMINE HONEY; HAVING EYES BUT  
SEEING NOT.

Please tell Mr. Ernest that I am now here to sift that yellow-jessamine story, as I am one of those who do not believe in poisoned honey. People will drink water after eating honey, and

so there happen a great many cases of fermentation in the stomach, called poisoning, to make out a case for some physician. And I believe that your grand botanists may be up to all known classifications of northern flora; but when it comes to the tropical flora and its immense varieties, they are completely at sea, and the reason is obvious. They can not examine and study them in the summer, their right season, but go to the tropics when every thing is dried up and there is nothing to see. Not long ago one of your taxidermists went to our section after birds, in the dry season, and was heard to say that Cuba was very poor in birds. The birds were then in the virgin woods, where they could get something to eat, and he could not find them. The same with many that "have eyes and see not."

Tampa, Fla., June 11.

C. CADALSO.

#### THE FOUL BROOD LAW IN MICHIGAN.

[Some little time ago I wrote to the Hon. Geo. E. Hilton, of Fremont, Mich., for a copy of the foul-brood law of that State. The following is his reply, together with a copy of the law in question:]

*My dear Ernest:*—Replying to yours of the 19th, I went through my "Public Acts" as far back as I have them, and then went to my attorney's office, and found an act that was introduced by Dr. Wm. W. Root during the session of 1881. I have had it copied, and you will find it inclosed. I consider it a splendid measure, but I don't believe there is one bee-keeper in a hundred in the State of Michigan who knows there is such a law upon our statute-books. It has never been amended or repealed, and is to-day in full force, and I would suggest the printing of the bill in GLEANINGS, for the benefit of the bee-keepers of America. GEO. E. HILTON, Fremont, Mich.

#### CHAPTER LXII.

##### PREVENTION OF FOUL BROOD AMONG BEES.

1881, p. 125, May 11, Act 141.

**SECTION 1.**—The people of the State of Michigan enact: That it shall be lawful for any person to keep in his apiary any colony of bees affected with the contagious malady known as foul brood; and it shall be the duty of every bee-keeper, as soon as he becomes aware of the existence of said disease among his bees, to forthwith destroy, or cause to be destroyed by burning or interment, all colonies thus affected.

**SEC. 2.** In any county in this State in which foul brood exists, or in which there are good reasons to believe it exists, it shall be lawful for any five or more actual bee-keepers of said county to set forth such fact, belief, or apprehension in a petition addressed to the judge of probate, requiring him to appoint a competent commissioner to prevent the spread of said disease, and to eradicate the same; which petition shall be filed with and become a part of the records of the court where such application is made.

**SEC. 3.** It shall be the duty of the judge of probate, on the receipt of the petition specified in section two of this act, to appoint, within ten days thereafter, a well-known and competent bee-keeper of said county as a commissioner, who shall hold his office during the pleasure of said court; and a record of such order of appointment, and revocation, when revoked, shall be filed as a part of the records of said court.

**SEC. 4.** It shall be the duty of said commissioner, within ten days after his appointment as aforesaid, to file his acceptance of the same with the court from which he received his appointment.

**SEC. 5.** Upon complaint of any three bee-keepers of said county in writing and on oath, to said commissioner, setting forth that said disease exists, or that they have reason to believe it exists within said county, designating the apiary or apiaries wherein they believe it to be, he shall become the duty of the commissioner, to whom such complaint is delivered, to proceed, without unnecessary delay, to examine the bees so designated; and if he shall become satisfied that any colony or colonies of said bees are diseased with said brood, he shall, without further disturbance to said bees, fix some distinguishing mark upon each hive wherein exists said foul brood, and immediately notify the person to whom said bees belong, personally or by leaving a written notice at his place of residence, if he be a resident of such county; and if such owner be a non-resident of such county, then by leaving the same with the person in charge of such bees, requiring said person, within five days, Sundays excepted, from the date of said notice, to effectually remove or destroy said hives, together with their entire contents, by burying them or by fire; but in case no foul brood is found to exist in said apiary, the persons so notifying, or any of them, shall be liable to said commissioner for the amount of his fees for such services.

**SEC. 6.** If any person neglects to destroy or cause to be destroyed said hives and their contents, in manner as described in section five, after due notification, and after the time above limited, he shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by a fine not to exceed twenty-five dollars, or by imprisonment in the county jail not more than fifteen days, or both, in the discretion of the court, for the first offense; and for each additional offense he shall be liable to a fine not to exceed one hundred dollars, or imprisonment in the county jail not more than sixty days, or both, in the discretion of the court; and any justice of the peace of the township where said bees exist shall have jurisdiction thereof.

**SEC. 7.** The commissioner shall be allowed for services, under this act, two dollars for each full day actually employed, and one dollar for each half day actually employed, the account to be audited by the board of supervisors, and paid in the same manner as all other county claims; but no fees shall be allowed by the board of supervisors to such commissioner for any services under this act unless foul brood is found to exist.

**SEC. 8.** In all suits and prosecutions under this act it shall be necessary to prove that said bees were actually diseased or infected with foul brood.

[There is already an excellent law in Wisconsin, and I hope later on to give a text of it in GLEANINGS. We shall be very glad to furnish copies of our journal, containing these excellent measures, to bee-keepers residing in States with no such law, and who wish to distribute them to members of their general assemblies.—Ed.]

#### FOUNDATION WITHOUT PAPER.

The foundation without paper came to hand all O. K., and is much less trouble than when papered. We prefer it in the strips. Honey is coming in nicely, and of fine quality.

N. E. DOANE.

Breckenridge, Mich., June 24.

[Mr. Doane has purchased several lots of foundation this season without paper. In all northern shipments the paper could be dispensed with to advantage to us and our customers, I believe; but we do not as yet dare to risk the experiment until we can hear from more like the above. For southern shipments it doubtless would be wise not to think of giving up the papering.—Ed.]

#### WHEN TO REPLACE OLD DARK COMBS.

I have some stands of bees, and the brood-comb is getting black and hard. Will you please tell me when is the best time of the year to remove some of the old comb and put in foundation? How many sheets should I remove at one time? R. A. WEDDINGTON.

Moulton, Tex., May 22.

[The best time to remove old black combs, or those that are in any way defective, is when there is the least honey in them. Usually that will be in the spring of the year, about fruit-bloom, or shortly after. Along in the fall also, when you are contracting your colonies to as few frames as they can occupy, you can remove the outside frames that are empty, and set them to one side. From this lot you can select the combs that are defective or dark, and replace them in the spring or summer with frames of foundation.—Ed.]

Friend Alkin's articles in the two last issues of GLEANINGS, in regard to putting up extracted honey in tin cans, are sound, and speak my ideas exactly. Something must be done along this line in disposing of extracted honey. You speak of placing 4½-lb. cans at your branch offices for sale. By all means place the size of 1, 2, and 3 lb. cans in your list as well.

Plattsmouth, Neb.

J. M. YOUNG.

## REARING QUEENS ON THE JONES SYSTEM.

You ask in GLEANINGS for reports on how the Jones system of rearing queens works. I would say that I have some fine queens with less work than when I had to dip the cells on sticks, *a la* Doolittle.

CHAS. STEWART.

Sammonsville, N. Y.

Our stores in this part of the State are being flooded with goldenrod honey put up in glass tumblers retailing at 10 cts. each. I send a sample by mail. If this honey is pure, no harm is done.

H. W. McCOMBS.

Richmond, Iowa.

[The sample in question was undoubtedly adulterated with glucose.—ED.]

Can you tell me where or how I can get a queen or nucleus of the giant bee of India? If so, what will be the probable cost?

It is disgusting to read the different articles in some bee-journals against the new deep-cell foundation and the giant bee, when the writers have never seen or tried either, and, one might say, know nothing of either. It is surprising to learn the number of narrow-minded, jealous writers we have to put up with. I shall be glad when we can get the deep-cell foundation. I believe it will be invaluable. I am using the new Weed process foundation. It is the finest I have ever used or seen.

J. W. GREGG.

Gazell, Cal., May 24.

[There is no place yet in this country, and may never be, where queens of this race may be obtained. See Straws, this issue.—ED.]

## SELLING HONEY IN A UNIFORM PACKAGE; BRO. AIKIN'S IDEA INDORSED.

On page 407 Bro. Aikin has opened up a good idea. I tried to get the Columbus Storage and Commission Co. to do this very thing last fall—to put extracted honey in cheap packages so I could sell to the groceries or to the consumer direct through the market; and now if I can get honey that I can guarantee to be pure, and labeled as it should be, I can sell thousands of pounds, as I have a good trade on comb in Columbus and at home, and I can do the same on extracted; but on account of there being so much on the market that is adulterated it would take some little time to convince the people that I was selling a pure article; but when this is done my trade will be enormous; and if there is a company formed to engage in this business I will give up my business and give all my time to the honey trade in Columbus and near-by towns; so I hope this matter will be pushed to the front. In this way I could get the producer a better price for his honey, both comb and extracted, than they can possibly get through commission houses. The way honey is now sold here, there are at least three commissions paid; while if I sold to the consumer there would be only one.

Blacklick, O.

D. M. RITCHEY.

Bees are still booming. We shall have lots of honey.

DAVID GROSSMAN.

Terrell, Texas, June 29.

We are having the heaviest flow of white-clover honey I ever saw.

C. C. EDDY.

Reinersville, Ohio, June 25.

At present we have the *first great honey-flow* from white clover for many years. My bees are just rolling in the honey.

M. N. SIMON.

Bloomdale, O., June 25.

Sweet clover beginning to bloom. I took 48 lbs. of comb honey to-day from one six-frame hive; others as good; will take off my first crop to-day and to-morrow.

D. M. RITCHEY.

Blacklick, O., June 24.

We are having the heaviest honey-flow I have experienced in the 17 years that I have kept bees. Swarms that were hived the first week in June have finished 56 sections besides the brood-chamber, and are swarming again.

England, Pa., June 30.

S. B. POST.

Wanted at once, 100,000 overcoats for bees so that they can gather a little of the thousands of pounds of honey hanging in the clover-blossoms.

L. B. THATCHER.

Somerville, N. J., June 15.

[When the foregoing was written it was doubtless cold; but to-day, July 3, it is 98° F. in the shade. Those overcoats will not be needed now.—ED.]

## THE GREAT WHITE-CLOVER YEAR.

If this is not the good old white-clover year again, what is it? This year will always be known as the great white-clover year. Here it is June 15, and I have 50 hives with 60 sections on each hive, two-thirds of which are sealed. The ground looks as if it were covered with snow, the clover bloom is so heavy; and lots of swarming too, but not with the L. hive. I have not had a swarm from one of these hives; but the bees in American hives are swarming badly.

Fremont, O.

CHAUNCEY REYNOLDS.

## A BANNER HONEY YEAR.

This has been one of the best seasons that Parke County bee-keepers have seen in several years. White clover has been very abundant, and yielded an unusual amount of honey. Other honey-plants have yielded in proportion to clover. At this date basswood has just commenced to bloom. Taking all together, the year 1897 will long be remembered as a banner honey year.

Rockville, Ind., July 3.

W. P. OVERMAN.

*J. M. C., La.*—It is quite a common practice to place two swarms together in the same hive. As a general rule, only one queen is killed.

*D. E. B., N. Y.*—You can put other bees on the combs coming from hives on which bees died the previous winter. The fact that the said combs contained candied honey will do no harm—at least for spring or summer use.

*G. W. S., Wis.*—The question as to whether bees are taxable property or not is one that can not be answered by yes or no. It all depends on the law of your State in reference to the matter. If you consult some attorney he will probably be able to tell you.

*D. B. H., Wash.*—It does little if any good to put any thing on a bee-sting, for the reason that the applied remedy can not reach the depth of the wound. It is usually best to leave it entirely alone. The more it is tinkered with, the worse it will become.

*M. E. H., Mich.*—The fact that you find the bees fighting at the entrance, with dead bees in front of it, is pretty good evidence that there has been robbing in that hive. Possibly the entrance is too large for the size of the colony, and should be contracted.

*J. B. W., Tex.*—The dandruff-like particles that you found in front of the entrance are probably the scrapings from the combs, or small pieces of cappings taken off when the honey is uncapped. When the bees have no use for this surplus wax they will carry it out at the entrance.

*H. E. M., Ind.*—Referring to your inquiry regarding the swarm of bees that came out and went back, and did the same thing next day, we would state that, in all probability, the queen was not able to follow. If her wing was defective when the swarm issued she would crawl out at the entrance, and, failing to fly, would crawl back into the hive, followed soon after by the bees.

*P. D. S., Pa.*—Swarms will very often come out the second and third time as you have described. You can usually make them stay the first time by giving them a frame of unsealed larvæ from some other hive. Then in hiving swarms it is always advisable to leave a very wide entrance, and leave the cover tilted just enough so as to give a strong circulation of air through the hive. When they get quieted down, then the cover may be closed over, and all will go well.

*W. L. S., Va.*—It is usually best to introduce queens just as soon as they are received in the mails. A queen may live in the cage one day

or ten days; but it is not safe to take any risk. It is not necessary to require a swarm unless, perhaps, the queen is an old one and should be replaced. Unless you desire to rear queens it is not necessary nor advisable to maintain drones in the hive. They should be kept out with the Alley trap, or, better, all drone comb should be cut out early in the season, and thus save the waste.

*J. C., Va.*—If your bees do not work to any extent in sections, inverting the hive would do little if any good. It is usual to put in what is known as a bait section—that is, a section with comb partially drawn out from last season. The bees will usually enter and store honey in this, and from this branch out to other sections; but unless the brood-nest is pretty well crammed with honey, bees will not enter the supers. Until the lower part of the hive is filled you can not get them to go above, and not in any event unless honey is coming in at a good rate.

*J. S. E., W. Va.*—It is proper to give the bees more room, but not toward the latter end of the season, when it is evident that clover bloom and basswood are drawing to a close. You can also place a crate of partly filled sections from one hive on to another. This is often done by practical bee-keepers—that is, the crate is given to a colony that is stronger, and more likely to finish out the season. For particulars in regard to the matter, see "How to Produce Comb Honey," in the catalog we are mailing you, p. 33. You can divide a colony in July, as you state, and, by paying attention to feeding, get them both in fine condition for winter. Better be careful about increasing too fast. Bees will increase fast enough, usually, during the swarming season. The eight-frame hive seems to have the preference now, and it may be made to take a large colony by using two brood-chambers.

*E. C., N. H.*—Regarding the queen and drone trap, which you have doubtless received, we would state that, by the directions on the end of the trap, you will see that a queen can be caught in the upper compartment, the trap detached, and placed among the flying bees of the swarm now in the air. We have sometimes attached the trap to a common garden-rake, and held it in midair until the bees had clustered upon it. Or a better way is to detach the trap from the parent hive and put another hive in its place, with dry combs or frames of foundation. Put the trap on this hive and the swarm will return. As soon as the bees are in the hive, let the queen run in at the entrance. If there was a super on the parent hive, put that on the new hive, and then the new swarm is ready for business. The old hive may be removed to another location. For fuller particulars on this question see our A B C of Bee Culture.

WE are still running night and day, but expect to be pretty well caught up by the 17th. The demand for shipping cases and sections is simply phenomenal.

UNDER Convention Notices will be found a letter from Dr. A. B. Mason, Secretary of the United States Bee-keepers' Union. He requests me to state that the information he gave on page 457, June 15, so far as it related to railroad rates, was not correct, and should be entirely disregarded; and he further says that what appears in Convention Notices is all right, and correct. Our readers will please take notice.

#### HOW TO DRAW A CROWD TO SELL HONEY.

IN our previous issue I promised to tell how to draw a crowd around groceries and other places where honey is sold. The experiment to which I shall refer was tried in Detroit. A large tobacco-firm, who were using honey to sweeten their tobaccos, and who desired to advertise the fact, employed a bee-keeper to place an observatory hive just inside the show-window. On top of the hive was placed a row of nicely filled sections of honey. Of course, the hive was arranged so the bees could not fly out, and every few days the bees were given a rest, and another set of frames was put in their place. The experiment was a success in every way. Great crowds congregated about the window, and the tobacco-store was full of men who wanted to sample the new honey tobacco. The crowds became so great that the police had to request the tobacco firm to discontinue their novel mode of advertising. They practiced the same method in another part of the city with the same success, and were, sooner or later, asked by the police to take the bees out of the window, as it interfered with traffic.

While GLEANINGS is opposed, first, last, and all the time, to the use of tobacco in any form, it recognizes that here is a legitimate mode of advertising that may very often be employed profitably by *bee-keepers*. Prepare a hive having one glass side. In the hive is placed one comb of bees, the bees being shut off from the rest of the hive by a tight-fitting division-board. As only one side of a comb can appear at once, one comb is sufficient. Over the frame of bees are placed four nicely filled sections of honey to which also the bees have access. The whole is neatly encased in glass. The hive is shoved up close to the show-window, and over it a neat card: "These bees belong to John Jones. His honey is for sale here. Inquire within."

I said in our last issue, and elsewhere in this

number, that, in view of the enormous honey crop, bee-keepers should take every means possible to work up their home markets. Here is a scheme. Try it and report.

#### HOW SHALL WE KEEP UP PRICES ON HONEY?

REPORTS are piling in every day saying that there has been a most tremendous flow of honey from white clover, and in some cases there is still basswood to follow. In another column we publish a few of these encouraging reports. We have not room enough to put them all in, but we give place to just enough to show which way the wind blows. But this large crop of honey places before bee-keepers a difficult problem; namely, "How shall we keep up prices?" In relation to this I make an extract from a letter just received from Harry Lathrop, a prominent bee-keeper of Wisconsin.

I fear a glut in the honey market, and ruined prices. The whole of Southern Wisconsin is flooded with white clover, and well-finished sections are now on the market, and the white clover season not half gone. Basswood, promising a large crop, will soon be in bloom. What can we do to save our market? Farmers who do not make a specialty of bee-keeping will sell their little crop at ruinously low prices, and make the price for the bee-keeper who depends on his honey crop alone. Supplies and general cost of production are as high as ever. Sections from most factories cost more this year than last. If you could reach the people I refer to you could advise them not to sell their honey too low; but you can not reach many of them. No one in this country ever saw as much white clover in bloom at once as there is now. The year 1893 does not compare; still, there is too much rain for strictly first-class work in storing. Though I have colonies that have given two full supers of extracted, the quality seems to be excellent, regardless of the rainy weather.

Browntown, Wis., June 30.

H. LATHROP.

It is true, that farmers who make no specialty of bee-keeping will sell their crop at ruinously low prices. I do not know of any way to do except to ascertain who have produced honey, and go around personally and ask them to agree not to sell lower than certain prices. This would not be a combine nor a pool, but simply an effort on the part of honest bee-keepers to protect themselves from ruinous prices. Such a move will enable the farmer to realize, at the same time, more for his honey. If there are only one or two and their crops are not large it might be well for you to buy them out.

In our last issue I cautioned bee-keepers against the policy of rushing their honey off to the city markets, and urged every one to sell around home as far as possible. When bee-keepers flood the great centers with honey it makes a glut on the market, and the published prices go into every little town and hamlet of the country; and, barring difference in freights, those city prices are almost sure to put all other markets on the same level.

A liberal use should be made of the honey-leaflets. When there is over-production, stimulate greater consumption. Bee-keepers everywhere should take honey-leaflets and distribute them around their locality and in their home markets. Let people know *why* honey is

a more wholesome sweet, especially if it comes direct from your own apiary, than ordinary syrups and so-called "strained honeys" that come from the cities.

The price of the leaflets is put away down so that you can afford to give them away. (See prices following the Honey Column.) The watchword, then, with bee-keepers everywhere should be, increased consumption of honey; for unless there is, prices will drop in obedience to the law of supply and demand. If there is a double supply, the thing to do is to *double the demand* if possible.

THE NEW DRAWN FOUNDATION; DOES IT MAKE "GOBBY" COMB HONEY?

Of course, this new article has been the subject of continued and careful experiment at the Home of the Honey-bees. Supers having a row of drawn foundation, and then a row of full sheets of ordinary foundation placed in alternation, have been placed on the hives, both at the home and at the out-yard. We have also given the bees supers containing sections filled with drawn foundation only. Now, what has been the result of these experiments? Just the same as those conducted on a much smaller scale last year. In every case the bees have accepted the new drawn foundation at once. As was to be expected, where full sheets of the new article were put into sections, the combs were attached, when completed, to all four sides.

Earlier in the season, when orders were pressing for the new foundation, we put into a good many sections only narrow strips about  $1\frac{1}{2}$  inches wide. These were placed in alternation with the old style foundation of the same width. The new article was accepted at once, and comb-building begun at its bottom edge, and continued down to the bottom of the section, nearly. In very many instances such combs were nearly completed before the bees did much with the narrow starters of *common* foundation, which they had gnawed in many cases. In one or two instances, where the supers of full sheets of drawn foundation and full sheets of old foundation were placed in alternation over *powerful* colonies, the old product was not so far behind in the drawing out.\*

"But," you may ask, "what kind of comb honey does the new drawn foundation make?" I suppose an ordinary fair test would be to compare it with comb honey made from full sheets of foundation. But Mr. Weed was determined to give it a more severe test still. Accordingly he brought in one of the sections completed that had been made from a narrow starter of *drawn* foundation. The lower portion, or that built by the bees, was, of course, natural drone comb. In my presence he requested two of the

printers to turn their backs while he cut a small chunk of comb honey from the natural-built comb, and one that had been completed over the drawn foundation, *both from the same sections*. Boss printer Hobart then took a mouthful of one, without knowing which one he took. He chewed it down to a piece of wax, and then took a mouthful of the other, and chewed that also. When asked to state whether one was more "gobby" than the other, he answered in the affirmative. On being asked *which* one it was, he named the second mouthful, which proved to be the natural-built drone-comb. To make sure that there was no mistake, another printer, Mr. Shane, was tried in the same way, only that the order of the mouthfuls was reversed, with the result in favor of the new product again. It seemed to me hardly *possible* that the Weed foundation would give *more pliable* comb honey with *less wax* than that built wholly by the bees, even though it were drone comb. Then the test was applied on me, with the result that I could see quite a marked difference in favor of the Weed. I asked Mr. Shane what he meant by saying that one was more "gobby" than the other. "Why," said he, "one is harder to chew."

Now, understand that this honey from the new Weed drawn foundation was put in to test over against *comb built wholly by the bees*, but which, as a matter of fact, was *drone* comb, and which they usually build for store purposes during the honey-flow.

It should be stated that natural-built drone is heavier than natural-built worker; but the bees don't build much worker comb for store purposes, as already stated. It will be seen that the fear that the comb honey from the new product be *more "gobby"* is groundless.

*Later.*—After the above was in type we tried again the same experiment that we did on the printers, with the exception that we placed comb honey from foundation in the test. The tasters were A. I. Root, my sister Constance, my mother, three of the machine-shop men who hardly know a bee from a grasshopper, and, last, the cook in our lunch-room. The verdict of all was that the natural-drawn comb was heavier and more gobby than either the drawn-foundation honey or that built from full sheets of ordinary foundation. As between the last two, the verdict was that there was no difference. Please understand that none of the tasters above mentioned had knowledge beforehand which sample was which. They were tested independently, with the result aforesaid.

To-day, July 12, I took home with me a section built wholly from a full sheet of Weed drawn foundation. I cut it out of the section myself. At the point where it was fastened to the wood, it seemed to resist the knife considerably; but beyond this the blade went through

\*This was the experience of M. G. Chase; but *powerful* colonies are not always to be had.—Ed.

the comb without any sensation of midrib, as is present when the comb is built from full sheets of ordinary foundation. Upon eating the comb I could not see how anybody could think it was *more gobby* than ordinary comb honey. Strange as it may seem, our household do not ordinarily care very much for honey; but Mrs. Root remarked how nice and tender this comb was. The whole section had delicate comb, and they all pronounce it fine—even the youngest, who sits by "papa."

Now, I do not believe that I am prejudiced; and if any one thinks I am, I hope such person will try the experiment of blindfolding two disinterested persons, placing before them samples of comb honey. That will surely eliminate the element of prejudice which is so decidedly pronounced on the part of a few of those who have seen fit to oppose the new article. One man condemned the new drawn foundation severely, even before he had tried it. Now, after having tried it on a small scale (three samples from our first dies that were very inferior to our present ones), on the principle of "I told you so" he condemns it just as severely again, saying that bees would not accept it, and that it had an "awful gob" to it. His experience is so opposed to our own, in the case of dozens of samples I have seen, that I must believe his prejudice quite ran away with his judgment. A few condemned ordinary foundation when it was first introduced into this country. They condemned it beforehand, and then condemned after they had tried it, saying that the bees would not accept it, etc. It is not at all strange that one who has condemned severely the new drawn foundation should do so now, after having tried it.

It is hardly time yet for reports to come in from the general field, for, in fact, we have not solicited them, except in a general way; but here is one just received from Mr. F. A. Salisbury, and it speaks for itself:

*Ernest R. Root:*—This afternoon I looked at the case of sections of drawn foundation that were placed on an average colony on the 8th inst., and find that all the sections were accepted by the bees, and drawn out still more by them, and filled partly with fresh honey. I took off one section and marked (in the hive 48-hours) to show bee-keepers. It looks nice. I shall take off another one on the 12th. I think you have a good thing if the price is not so high as to prohibit its use. I wish you would send me about 1 lb. more by express. I will test it alternately with foundation. This case was put on with all drawn comb. I did not think about alternating them when I placed them on.

F. A. SALISBURY.

Syracuse, N. Y., July 10, 1897.

Mr. Salisbury has been requested to place samples in alternation with ordinary foundation, and we shall await with interest the result of his further experiment. There are hundreds of others who have been testing the new article, and, of course, we shall be glad to hear from them too, whether their reports are good, bad, or indifferent. In the mean time I might add

that we have heard from Mr. Vernon Burt, who has been trying half a pound of the new foundation. He reports that it is a good thing; that it has only one fault; namely, *he can not get enough of it.*

Mr. John Iper, who has a few colonies out of town, has also been trying the new drawn foundation, with the result that he finds a decided preference on the part of the bees for the new article. Said he, "The bees begin to store honey in it immediately; and then after the comb of the drawn foundation is filled and well under way they begin on the starters, in the ordinary way." He has not yet tested the eating quality of the two kinds of comb honey.

Mr. M. G. Chase, owning some 125 colonies seven miles from here, at Whittlesey, has also been testing the new product. He placed in one super a row of sections of drawn comb of the previous season of full depth, a row of the Weed drawn foundation  $\frac{1}{4}$  inch deep, with a piece at the top and a piece at the bottom of the sections; also a row of full sheets of common foundation. The full-depth comb was entered first of course, then next the drawn foundation. After the work was well begun in these then the bees drew out the common foundation. If the drawn comb had been leveled down to the same depth as the drawn foundation, the bees, he thought, would have taken one as quickly as the other.

To-day, July 13, he brought me up representative samples showing each of the three lots. Sections after being completed, containing either the drawn comb or the drawn foundation, weighed from one to two ounces more than sections that contained full sheets of common foundation. I have the samples in our office now, and shall be glad to show them to any one who wishes to see them. One thing that is quite marked in favor of the new drawn foundation in sections is that the bottom of the section is built on to as solidly and as perfectly as the top. This was owing no doubt to the fact of the bottom starter of the new article.

#### OUR OWN APIARY.

NEVER, in all the time that I have had to do with bees, unless it was during that remarkable year of 1870, when I was too much of a lad to know much about bees, do I remember of such a remarkable honey-flow as we are having from white clover. Our hives, especially at the out-yard, are stacked up two and three stories high. At this writing, July 12, honey is still coming in from clover, although it is evident, from the brown heads that have gone to seed, scattered through the fields far and wide, that nectar from this source, at least, will soon cease.

I stated in our last issue that basswoods would probably be a failure in this part, as no buds appeared on the trees; but it seems as if I must have been partly wrong, for the bees are

beginning to drop in at the entrances as if they were getting honey somewhere. Mr. Vernon Burt, a few miles north of us, is very certain he will get some honey from basswood, because he has seen the promising buds on the big forest-trees. After all, I suspect it is these big trees that really yield the bulk of linden honey. Very often I have seen the small trees, loaded with blossoms, turn brown and go to seed, without a bee once going near them.

During the last two or three weeks I have spent many an hour helping the boys do the work in the apiary. While I might hire some one else to do it more cheaply, I believe nothing in the world is so helpful to a bee-journal as for its editor to go out into the apiary and see what the bees have to say about many of the problems that confront us. I believe, therefore, GLEANINGS can afford to have me "waste" a little time. There are several questions that I have been holding back, waiting for the time when I could lay them before the bees. Among them was the question of

#### BEES HANGING OUT—WHAT IS THE CAUSE OF IT?

I had a vague idea that, if we were to make sure that the bees were never crowded for room, in the first place, and the hives were properly shaded, with good-sized entrances, there would not be any of this hanging-out; and the result of careful experiment and observation this season seems to show that this is true. At our out-yard there has been no hanging-out, but quite a little of it at the home yard. The work in the home apiary at the beginning of the flow got behind. At the out-apiary I made sure to keep pace with the bees. As there would be no one present to look after swarms, it was decidedly necessary that the bees should not get into the *habit* of loafing. There was no loafing here, and only one swarm, and that came out several times while I was away.

As every one knows, hanging out and sulking at the front of the hives shows that something is not quite right. A colony in the height of the honey-flow should have no loafing or sulking bees. I told the boys I did not want to have one hive with its bees hanging out in front, even at night. They did not believe that the poor bees could *help* coming out when the nights were so hot; but I noticed that stronger colonies in the same apiary were busy at work in the sections, without a loafing bee in front. I said to myself, "We must make these other chaps (the loafers) get down to business like the others."

As I found years before, so this year, smoking them in did no good. They would come out again just as soon as they got through "rubbing their eyes." Giving them frames of foundation and plenty of room sometimes answered, but generally they would cluster out even then. Furnishing the bees a good deal of shade helped somewhat. Giving them very wide deep en-

trances sometimes caused them to go into the hives and go to work.

This hanging-out is indicative of swarming. Early in the season, perhaps the bees are a little cramped for room, and they get into the "habit" of loafing; and this habit, once established, is hard to break up; or perhaps the entrance is too small, or the hive not properly shaded. Any one or all of these conditions may start the habit, and the only way to break it up is to make the bees *think* they have actually swarmed. I am satisfied that, while the bees are loafing and hanging out at the entrance, they are waiting either for the queen or some of their number to start a swarm forth.

There were several of our colonies at the home yard that seemed to be very stubborn. Two of them would hang out in spite of the fact that I personally alternated every one of their frames of brood and honey with frames of foundation. The *habit* had been established, and, no matter what I did, they *would* hang out. Finally, the thought occurred to me to take the hive away entirely (a big two-story chaff one) and put in its place an entirely different hive—a single-walled Dovetailed made up of three stories. This was done and the frames put into the new hive. The greater portion of the bees were shaken out in front, and were made to crawl in at the entrance. The bees went to work, and there was no loafing from that time on. Another hive was treated in a like manner with the same result.

I am fast coming to believe that, in a well-regulated apiary, there should not be a hive with bees hanging out in front. Just think of the waste of over half a colony loafing and doing nothing for days until they swarm, and a super or two of sections without a bee in them! We know perfectly well that, when bees swarm, they will go to work—that is, providing they are put into another hive, and their mania satisfied.

In the foregoing I have enumerated a number of conditions that cause bees to hang out; but one I did not mention; namely, that of queenlessness. Several of our good strong colonies were working nicely until we took away their queens. They immediately began to sulk, and to hang out. They knew something was wrong, and I think they had a sort of idea if they could once swarm, all would go well again. So they thought they would hang out. When these same colonies were supplied with a queen, the loafing ceased and the bees went to work.

I have been watching the matter very narrowly, and I have about come to the conclusion that, for our locality, we do not want a colony with a caged queen or one queenless in the hive. Bees seem to do very much better when there is a queen laying, and brood in all stages; yet I recognize that some good apiarists succeed well with caged queens.

## OUR HOMES.

And the man of God was wroth with him, and said, Thou shouldst have smitten five or six times; then hadst thou smitten Syria till thou hadst consumed it whereas now thou shalt smite Syria but thrice.—11. **KINGS 13:19.**

Then came the disciples to Jesus apart, and said, Why could not we cast him out? And Jesus said unto them, Because of your unbelief; for verily I say unto you, if ye have faith as a grain of mustard seed, ye shall say unto this mountain, Remove hence to yonder place, and it shall remove; and nothing shall be impossible unto you.—**MATT. 17:19, 20.**

People who knew me in childhood, and those who have visited our place at different periods, often express surprise at a business of such magnitude, built up in so short a space of time; and especially so as I commenced entirely without capital, and with a comparatively frail body besides. Now, do not feel troubled, good friends of mine. I am not going to boast in this Home Paper. If it sounds like boasting, it is because you misunderstand me. I am going to write to-day that I may give you help in your own homes, and not that I may help or brag about myself. Please keep this in mind while I give you some suggestions that I hope and pray will be helpful to you. And let me say that the work I enjoy above all other things in this world of ours is in being helpful to my fellow-man. When I get among people, or in circumstances where my skill and experience are of value, then I am happy; and whenever I find myself in a place where it seems I am not needed, then I am unhappy; and so far as pay is concerned, as I get older I begin to long for the privilege of working where pay does not enter into the matter at all.

Many times visitors, and these friends of whom I have been speaking, have asked me the question, "Mr. Root, what is the secret you possess? Why is it you find so much to do, and how is it that you succeed in setting great crowds of people at work while others all about you are complaining that there is nothing to do, or nothing to do that will pay decent wages?" I think the answer goes along in the line of the first of the two texts I have chosen above. The man of God was "wroth." I like that word *wroth*; and I believe it would be a good thing for us all if a godly and sanctified wrath were to stir us up a little oftener than it does now. Why! some of these bright summer mornings, when the sun begins to make it feel unpleasantly hot, I have felt an almost overpowering inclination to sit still in the shade, and let things run themselves. Yes, I, like yourself, know exactly what it is to have these feelings; and I have prayed again and again for deliverance from this sin of half-heartedness. Now, you may think it a little funny, but the prayer many times seems to be answered by the prince of darkness, and he would very quickly run me into worse troubles than half-heartedness if I did not speedily call on the great Captain, under whose banner I am enrolled, for help and protection. Am I speaking in an enigma? Well, then, let me explain that my half-heartedness is often cured by seeing somebody else half-hearted or criminally stupid. Then my "Root temper" comes up. Satan prompts, no doubt, that I should wake up the half-hearted person with a rush; but old experiences warn me to be careful; and before doing any thing, if I breathe my little prayer, "Lord, help me to right this wrong in a right and proper manner," then I am pretty sure to keep in the straight and narrow path. Let me give you one among many illustrations.

Some time in the latter part of March, when those beds of Grand Rapids lettuce were just getting beautiful to the eyes of all beholders, they also seemed beautiful to our flock of chickens domiciled not many rods away. The weather was getting warm enough for them to begin to make exploring expeditions. They had been fed refuse lettuce from the greenhouse until they knew what it was. One day, when they wandered farther than usual, the whole flock caught a glimpse of the brilliant coloring under the rays of the March sun. I can imagine those biddies as they tipped their heads one way and then another, and ventured cautiously up to the edge of the lettuce-beds. No one was around just then, and that sifted rich mellow soil offered rare inducements for scratching and wallowing. No doubt there were angle-worms in that protected soil. Perhaps the chickens had not had a taste of the worms nor of the lettuce for some time back. I need not tell you the rest. You know something what havoc an enterprising flock of hens will make in just a few minutes in a bed of luxuriant garden stuff. For a time we kept them away by tilting the sash just enough to let in air, but close enough to keep out chickens; but this deprived our beds of the great benefit of a summer shower. We had tried frames of poultry-netting, to be put on when the sash was taken off; but these would cost a good deal, and they were more or less in the way when on the beds or off. I told the boys if the hens were driven away with a *tremendous scaring* I did not think they would come back again, especially as their forage-ground was off in another direction. Well, the boys chased the chickens off, but they came back just as soon as another opportunity offered. I made up my mind that, if the hens were sufficiently scared, they would stay away; but I could not think of a boy who would do the work according to my ideas unless I first gave him a copy. The boys were in their teens, and I am toward sixty. Notwithstanding this, I think I can beat any boy out in giving either hens or dogs such a fright that they will never want to come around that way again.

I finally found the hens, with the rooster leading and bossing matters, right in the mischief. I took off my hat and came up slowly until I was pretty well in the midst of the flock. Then with my hands and feet and voice I made such a racket among the poultry that I am sure the most of them will remember it as long as they live. I ran after the old hens and over them, and scared them with my hat until, out of sheer fright, they could not run any more; then I gave the rooster, as the ringleader, such a scaring that he could hardly cackle. They were glad enough to find refuge in their own quarters; and after they got breath enough they cackled over the event for an hour or more afterward. I do not know enough about hen language to tell just what they said, but I presume they thought it was monstrous to make all that racket and fuss about a little bed of lettuce. One thing, however, is certain: I have not seen them, either singly or together, around those lettuce-beds since. We did not have any poultry-netting to fuss or bother with, either. I know they remember it, because, when I go through their quarters on my wheel, on the way to the creek bottoms, they will cackle and run as if they thought they were to be chased again as they were on that eventful March day.

Now, it is the same way with dogs. I have told you how much trouble they make by walking over our glass sashes. If the dog is a big one, crash, crash, crash, it goes every step. I do not want to hurt the dogs, and I know the law would permit me to shoot them where they

come around and make us trouble without their owners. But I simply want the dogs to *understand* that our fourth-acre of plant-bees is forbidden ground. I have tried to have our boys give each dog as it comes around a good wholesome lesson by way of a fright, but they don't seem to get the hang of it as I do it. Let the dog alone until you get your hands full of sticks or stones, or whatever you can gather up hastily; then get up near enough so you can keep pretty close to him in the chase. Follow him with shouts and peltings, and he will soon learn where it is that he must not go.

A good many times I am impatient at the way people handle horses. A horse that is always starting before you are ready can be thoroughly cured of it by a little faithful *whole-hearted* work. The same horse or horses that will *not* start when you tell them to can also be cured by a little judicious use of the whip. Perhaps there are horses that never need the whip, but I have never found many of them. Valuable lives are lost every day because of half-heartedness in handling and training horses. Now, please do not misunderstand me, dear friends, when I go farther and say that valuable lives are lost, not only in body but in *soul*, because of half-hearted parents. If you give up to the chickens, and give up to the dogs (or, if you choose, *neighbors'* chickens and dogs), you have simply lost your garden and its enjoyment; but when you give up to the child, and say you have done the best you could—that you could not make him mind—then you are responsible for the loss of an *immortal soul*; and you need not be surprised if your gray hairs are brought down in sorrow to the grave.

Before I get through with dogs and chickens I want to say a word about rats and mice. Since I have been trying to build up our business, again and again have rats and mice assailed us. When I protested, our people, different ones, at different times, would say, in effect:

"Well, you can not keep them out; and it is no use trying."

First, the cats would be "no good;" then the traps were no good; or the "rough on rats" was no good. I can not go into detail here; but on personal investigation I found that the *cat* had not been treated properly. Many times pussy was overfed. Then there were no cat-doors so these faithful friends could have access to every nook and cranny. The traps were not properly examined *daily*. Again and again have I found trapped mice left until they were smelling badly. The bait was old and dried up. The traps were not "daintily" adjusted so as to go off at the first touch. For rats, the steel traps were not properly smoked to remove the smell of former transactions; and they did not try bedding them in the sawdust or fine dirt right under the runs. After I taught a boy (or girl either, for that matter) just *how* to manage traps, we had little or no further trouble. Several times I found people who declared they had used "rough on rats," and it did no good; but upon inquiry they had not even once read the printed instructions accompanying each box. Oh how much trouble I have had from things that would not work because the party to whom the thing was intrusted never read the "directions for use!" I have had grown-up men and women coolly inform me they threw the directions away without looking at them.

I once sent out two old farmers into the field to use a Meeker disk harrow. They drew it around the lot almost half an hour *upside down*, without ever so much as looking at the directions securely tacked on the machine, telling how to use it. Somebody will say, "Oh! you are talking about *hired* help; but if these

same people were working for themselves they would, of course, take some interest in what they were doing." Well, I have watched this thing, and I am glad to be able to say that these same people, when they were working for themselves, in and around their own homes, managed pretty much the same way. They do not give the matter in question enough thought, energy, and vehemence to make it succeed. Again and again these friends of mine around me say to me, "Oh! you might as well give up; the thing is no good. We have tried it in every way, shape, and manner, and it positively will *not* work." But it does work, sooner or later, when I get hold of it. Perhaps some of them think I make a big fuss about nothing; but I certainly succeed in keeping people at work, and in paying them their wages every Saturday night.

Let me digress right here to say that of late years it is my son and son-in-law who should have the credit of managing the greater part of our business, and not myself.

A good brother who lives far away sent us \$3.00 for some goods to be sent by mail. He wanted first \$2.40 worth of foundation; then he wanted some slates to hang on his hives. He said in his letter he wanted his goods as soon as they could be got to him. The foundation was already packed and put up, and could have gone by return mail. The slates were supposed to be in the counter store. In order to make one package, the letter went to the store below to have the slates sent up. Where goods go by return mail, or, say, next day, we have not been in the habit of receiving the money; therefore, when it was discovered that some slates were ordered but none were in stock, the letter was held until the slates should come. In the mean time the slate-maker reported he was too busy on other jobs to fuss with little slates for hives. At this crisis the letter should surely have gone back upstairs to have the foundation mailed, informing our customer in regard to the slates. Not so, however. Nothing was sent and nothing was done until I investigated the matter, fully two weeks after the money reached us. I told our friend to make out his bill for damages, and we would try to pay it. And may I right here intimate that a sure and complete remedy for all cases like this last one is the scripture injunction to love your neighbor as yourself? Any man who tries even a little to put himself in his neighbor's place would not be likely to see his neighbor lose a part of his honey crop when nothing at all prevented his having at least the greater part of his order go by return mail; and, in fact, love to God and love to one's neighbor should be a perfect cure for all half-heartedness of whatever nature.

Just one more illustration right here:

A week ago the man who runs the Planet cultivator told me he could do ever so much better work, and save his strength at the same time, if the handles of the cultivator could be raised.

"Why, Mr. B., this cultivator is made just on purpose so you *can* raise or lower the handles to any point you wish."

"Well, I supposed that it was made in that way, but it is not. Loosening the bolts which seem to be made for that very purpose will not permit the handles to go up and down a particle, as you will see."

I took hold of the wrench, got down on my knees in the dirt, and I *did* see. What do you suppose I saw? Why, I saw that, when the cultivator was set up, four or five years ago, the man who put it together put a certain casting on upside down; and in all that time, all

the men who had used that cultivator had been annoyed and hindered in their work summer after summer. Not one of them had, until this present time, informed me that the cultivator as it was could not be made to do its best work. Why didn't some of them talk to me as I came around, and tell me about it?

A few days ago our young chickens were going, one every night. After a brood of eleven had gone clear down to three I began making a stir in the neighborhood. About a week before, Mrs. Root had befriended a "tramp" cat. After the cat had been fed and made at home—that is, when she became sufficiently acquainted—she brought forth from their hiding-place four bright kittens, one after another. I soon decided that the tramp cat was responsible for the loss of the chicks; but the whole family said I was mistaken, as she was so kind and gentle, etc. Finally the teamster said one of the men who was mowing the lawn told him he saw the tramp cat with one of the chickens in her mouth. That was probably one of the first of the eleven. I passed the man ever so many times a day, and he could not scrape up energy enough to tell me he saw the cat that was taking my chickens one by one. I questioned him about it, and remonstrated because he did not tell me at once, instead of telling somebody else; but he had nothing to say. After the cat was killed, then (not before) he volunteered the information to Mrs. Root that it was not the cat that had the four kittens, at all. It was a yellow cat that he saw with a chicken in its mouth. According to this I had killed an innocent cat, and left her four "orphan" kittens to get along the best they could.

Now, a few chickens and a cat are but trifles, I know; and perhaps I should not mention them at all were it not that I am expecting some choice Minorcas to hatch some time this week, and I do not propose that one of *them* shall be taken off every night, by considerable. As I said, chickens and kittens are but trifling matters; but we have more or less the same state of affairs all over our establishment. In one of our elevators, belting to the amount of almost a hundred dollars has been destroyed because we could not get the men who use the heavy freight-elevator to pull the lever clear up sharp either to one side or the other. When the lever was left pulled part way a belt was burned, so a new one had to be put in its place. It would be exceedingly convenient with our freight-elevators to let each man who is moving freight handle the elevator, but we had to give it up. Two men have now the elevator in charge, and a sign announces that they must be called whenever it is to be used. The whole great business world realizes how hard it is to find men who will learn all about the business they are connected with, and make it their study to save their employers from loss. With almost a world full of people wanting something to do, men who will *think, act, and talk* so as to save loss are *always* hard to find.

The loss of belting and the loss of life are serious matters, especially when life is lost by somebody's half-heartedness; but, my friends, there are more important problems that meet us almost daily than even this. The Master tells us to beware of him who is able to destroy both soul and body.

□ In the last of our two texts the disciples asked the Master why it was they did not succeed in banishing the evil spirit from one who was brought to them. He told them it was because of their unbelief; or, as I should put it, in consequence of their half-heartedness. They failed in routing the evil spirit very much as you and I fail in getting rid of rats and mice—par-

don me for the illustration. People all around about us admit themselves helpless victims of evil habits. One man said to me, not long ago, when I was remonstrating with him, that he could bring me a testimonial from different physicians to the effect that he was no longer *responsible* for his occasional sprees. He said the doctors told him that he could not help it, even if he *tried*. May God have mercy on the doctors if they really did say this. Our readers are aware, of course, that I would not say, under any and all circumstances, that a man can by his own will power break off every evil habit; but I do say it is my belief, that, while there is life and reason, any person can, *with God's help*, be emancipated from *any* evil habit.

But a few hours ago a poor friend wrote me, telling of his struggles in breaking the bands of Satan. In his despair he was contemplating something that is, if not suicide, almost next door to it. Although a professing Christian, he said he had "lost his will power." Just as soon as he explained to me the circumstances I felt like rejoicing that I could furnish a remedy that would help him out of his troubles as safely and surely as you would help a man out of a millpond by taking hold of his hand. Then my enthusiasm was somewhat dampened because I remembered my remedy would require "will power." Please do not smile when I tell you that I wrote to him to change his diet to one of lean meat; cut off starch and sugar entirely. If he can do this he is saved; but, alas! it requires will power. By the way, when I meet either a man or a woman of late who has gone through several months on a clean lean-meat diet, I feel like lifting my hat to such, out of reverence and respect. The person who can control his appetite to the extent of cutting off the last crumb of bread, so that his diet may be absolutely *unfermentable*, has will power to fight almost any temptation that flesh is heir to. I do not know just what effect the lean-meat diet would have on intemperance; but I suspect it would take off a great part of the craving for intoxicants. If there is any one among our readers who can give me any information in regard to this matter, either for my own private benefit or for the public, omitting the name if he chooses, I should be very glad indeed to get such testimony. I want to know to what extent our diet is responsible for our peculiar besetting sins.

Now, then, dear friends, I suppose God leaves us all to choose. Shall we drift along in idleness and in shady inaction until disgust of life, and then suicide or imbecility, comes on? or shall we waken up and use our brains and muscles, and make things come into shape as they ought to? Sin is in the world. Shall we let it go on, or shall we say, "God helping me, this shall continue no longer"? There are illustrations all about us, showing what energy, perseverance, and vehemence will accomplish. There are also illustrations all about us of the result of letting things drag, and go as they happen. Shall we get along through life contriving to get rid of the precious hours God has given us, with the least possible exertion or trouble, until we slip into our graves? or shall we stand up like Christian of old, with our armor on, and rebuke sin and sloth and half-heartedness at every turn?

---

#### SELLING RECIPES FOR DOING THINGS.

*Dear Gleanings:*—In the Chicago *American Poultry Journal* for April, '97, page 122, is an advertisement headed "Bees for Nothing." I have not the \$3.00 to throw away, so I do not feel like investigating it. The advertiser is A. F. Randolph, Green Valley, Ill. Ionia, Mich., June 12. HARMON SMITH.

As it is the business of GLEANINGS to keep its readers posted in regard to every thing new that comes up in bee culture, we sent the three dollars. It is printed on page 11 of a little price list of fancy poultry. Here is the three-dollar recipe verbatim:

DIRECTIONS FOR TAKING RUNAWAY SWARMS OF BEES.

Prepare an ordinary box hive by having it sweet and clean; place a stick one-fourth of an inch thick about six inches from the top across the inside of the hive and a similar one crosswise of the first, six inches lower down for supports to the comb. Now take a piece of empty comb or comb foundation and fasten to the inside of the top of the hive by melting a bit of wax and sticking the comb fast while hot; now drop a few drops of the sweet oil of anise on the comb and the inner walls of the hive; now fasten on the bottom-board, letting it extend an inch or two beyond the hive on the front side, leaving a slot four inches long and three-eighths of an inch deep for an entrance; on the first real warm day in May, when the bees begin to swarm, place your hive in a shady tree, not necessarily very high from the ground; the bees will swarm from the parent hive; and as soon as they settle they will send out scouts to look for a new home; and, if not successful, the swarm will make a flight and settle, and send out scouts again as before, and continue to move and scout until they find a hollow tree or some cavity that suits them, when they immediately take possession. Now, if you have a few hives scattered about through your orchard, and a swarm is passing within two miles, the scouts will find your empty hives ready for occupancy, and will lead the swarm to the hive. If your hive is secured firmly, it can remain in the tree until cool weather before removing.

Our readers will notice that, in the above, there is not a single idea that has not already been published repeatedly in our journals. Several years ago we had quite a discussion in regard to the matter, and many articles were published in regard to it. I confess that it somewhat revived my old enthusiasm in regard to decoy hives. But, hold on a minute! There is one new feature. It is the statement to the effect that, if a swarm passes within *two miles* of your empty hives, the scouts will find them. We did not know before that a swarm of bees keeps scouts out for two miles in every direction; and I am afraid we do not know it now. We have here another illustration of the fact that I have for so many years emphasized: No good thing ever comes, or, perhaps I should say, no *new* thing ever comes from those who advertise recipes or secrets for a certain sum of money. Now, if anybody else who takes GLEANINGS knows of any valuable secret offered for a certain sum of money, just let GLEANINGS know about it and we will enjoy it all together instead of sending three dollars individually for one and the same thing.

He shall be like a tree planted by the rivers of water; . . . his leaf also shall not wither.—PSALM 1:3.

I have before mentioned that my neighbor, C. J. Green, found a little spring on one of his lots. He piped it down into his dooryard, and near his greenhouse he has a little fountain. Now, during a severe drouth like the present there is not very much water—perhaps as much as would fill a rye straw or a little more; but even this small amount keeps two considerable tanks full, and the surplus runs the tiny foun-

tain; and right where the overflow from this fountain reaches it, is a small Downing mulberry-tree. The tree is fairly filled with the most luscious mulberries I ever tasted; and the tree is making such a luxuriant growth that it is really a pleasure to look at it. While I stood enjoying it, just between sundown and dark, I was reminded of three things: First, that the Downing mulberry is a most delicious fruit when grown to perfection; second, that it seems to be a water-plant. Like the willow, it delights in water continually; third, the whole thing was a most beautiful reminder, by way of an object-lesson, of that wonderful verse in the first Psalm. We have a Downing mulberry-tree on our lawn, but the berries are small, and insignificant in flavor, compared with the one I have just spoken of. But I am inclined to think it is not altogether the water. Occasionally there are trees that bear larger and finer fruit than others. Mr. Green has already set some grafts on another mulberry-tree on his premises to see if he can get equally large and luscious fruit.

"HAPPY SURPRISES;" THE PORTER APPLE.

Nearly a year ago a niece made me a present of a luscious apple, so very large that I at once made a trip of investigation. She said she did not know the name of the apple; the tree was on the premises when they moved there. I was astonished to find that I had never before known of so large an apple, almost if not quite as early as the Early Harvest. I sent a sample of the apple to our Ohio Experiment Station, and they replied right off that it was the Porter. Last fall I sent to our nurseryman, Mr. Job Green, of Granger, Medina Co., O., for one-fourth dozen trees. Well, yesterday, July 8th, the timothy in our orchard was so high that we cut it and put it into the barn; and after the grass was out of the way, one of my Porter apple-trees, set out just last fall, and not more than four or five feet high, was found to contain two great beautiful apples almost ripe. Now, if you have never tasted this apple, plant a tree in your dooryard, in a good rich place, then you or your children will have a good lot of "happy surprises" in the way of a beautiful fruit when everybody wants it most.

THE FOURTH OF JULY, 1897.

This present year seems peculiar in at least two respects. First, it has given us the coldest day since the Weather Bureau was started, some 27 years ago; and on the 4th of this present month the thermometer registered the *highest* point (according to the Weather Bureau) in 17 years. On the north side of our brick building the thermometer registered half a degree above 100; but on the porch over at the house it was only about 97. The Weather Bureau reports it at their office, on top of one of the tallest buildings in Cleveland, somewhere about 99, if I am correct. It is hard to make a correct statement, because the surroundings have so much to do with the temperature.

Unfortunately—at least so it would seem—it was announced that your humble servant would give a talk in a church five miles away from my home, on Sunday afternoon. I did not want to take a horse out in such sultry weather, and, in fact, I did not want to ride in a buggy, so I rode on my wheel. Several urged that it was positively dangerous. But I knew pretty well it was not dangerous for me, and I was agreeably "surprised" to find myself much more comfortable on the wheel than sitting indoors in the shade. As my talk was about "happy surprises," my experience came in very opportunely. I left home at one o'clock, and

got back about half-past three; so I "took in" the highest temperature of the torrid wave.

Well, the hot sun and hot wind did not hurt me at all (oh! I forgot; I do not know but it *did* make my nose a little redder than usual), but it cooked our great big Columbus gooseberries, and almost spoiled our crop; but some of the berries of smaller size, such as the Downing and Houghtons were harmed but little or none at all. Our new friend *Eleagnus longipes* was also roasted more or less by the heat. Strawberries, unless they had some sort of protection, were more or less cooked. And this reminds me that it is an excellent thing to have at least a part of your strawberries grow in the shade. The shade of a large tree is just what is wanted, providing you do not let the roots of the large tree take all the moisture from the strawberries. A sub-irrigating bed under the shade of a tree, with the bottom of the bed cemented so it will hold water, would fix it to a dot. I am inclined to think some growing corn on the south side of the strawberries would answer a very good purpose. I studied the matter in several localities on our grounds enough to be certain that, with a season like this, shade of some kind would be a profitable investment to the strawberry-grower. I have not had a chance to test plants on the north side of a building or a high board fence, but I think it would be just the thing. Of course, this is only for *late* strawberries. For early ones you want the sun at least the fore part of the season; but for *raising plants* during the month of July, even if you have plenty of water, some shade during the heat of the day would help matters along very materially.

#### GARDENING FOR JULY 15; WHAT CAN WE PLANT?

You can plant almost all kinds of beans (except the large limas), and they will usually escape frost, Henderson's bush lima included. Beets will do nicely if you have a market for table beets, or beets tied up in bunches. You can put out carrots, cauliflower, and celery-plants. Ford's Early sweet corn will do nicely if planted on good ground. Cucumbers are just in their element this hot July weather. Give them good rich ground; and if you have plenty of rain, and keep the bugs off, you will have a crop. Grand Rapids lettuce will do nicely, and will sell in almost any locality if you shade it from the hot sun. Have it in rich ground, and make it crisp and white. You can sow all sorts of onion seeds for sets; and the American Pearl may be sown now, not too closely, and left to stand over winter. The only trouble is its inclination to send up a seed-stalk in spring. But you can fix this by pulling out every one as soon as it begins to show a seed-stalk, and selling it as bunch onions—see our bunch-onion circular. If you want to make a plantation of the winter onions, now is just the time to do it. Gather the sets, and plant at once. Any of the early peas will make a crop if planted now; and in our locality we generally get large peas, like Champion of England, when sown before July 15. We are going to put in a lot of them right away. Radishes you may plant every day for the next 60 days; the same with spinach. If you have great big strong plants ready to blossom you can put out tomatoes now. All kinds of turnips can be sown now, but I would not put in a great many if you want them for table use, because they get too old in just a few days after they are just right; and, while I think of it, get in plenty of wax beans so you can supply the market until the time frost spoils them. Bunch yams and vineless sweet potatoes will

usually make a crop if put out now with sufficient care so they commence to grow right away. You can also plant potatoes at this late date if you have some good seed already sprouted, having the sprouts not too long. Jersey Wakefield and Henderson's Early Summer cabbage-plants will do nicely if put out now. Late kinds will head up if the fall is favorable; and we consider it the very best time to grow cauliflower by putting out your plants by the middle of July.

Last, but not least by considerable, we consider July the finest month in the whole year to put out strawberry-plants if you have learned the knack of making them grow in hot weather. Potted plants, or plants taken up with our transplanting-machine recently illustrated, will go right along all right unless you have a tremendous drouth. I think it will pay every strawberry-grower to learn how to increase his stock of choice high-priced plants by planting in July. If the weather is very hot and dry, keep things moving by the use of plenty of water, and shading them with cotton cloth.

#### JADOO FIBER.

Doubtless many of you have read of this new material for florists and gardeners. We are using it for potted strawberries; and it is so much lighter than soil I have hoped that we might be able to send the new strawberries out in the shape of potted plants *by mail*. Of course, the postage will be more; but you will have a plant that will put out runners, and push ahead the very day you get it in the ground. When I have samples ready to mail I will let you know, and I will also report in regard to this new material, jadoo. We are also testing concentrated jadoo liquid. Permit me to add that jadoo itself looks very much like nice swamp muck. It costs at present about \$30.00 a ton.

#### IS SWEET CLOVER A NOXIOUS WEED?

How to exterminate sweet clover after it has got a good start is something that I am very much interested in just now. If you or any one else knows of any practical method by which one can kill it out, almost everywhere, and especially myself, would be very thankful for the information.

Eight or nine years ago I bought some sweet-clover seed of you and sowed it on my own premises, and also along the public highway. A friend of mine got some seed soon after, and he too sowed it along the roadside. Now the clover is pretty well set over perhaps five or six miles of the public highway. At first but little attention was paid to it, no one seeming to know what it was; neither had I the least idea what I was getting into when I sowed it. Now it is growing up along the road higher than the fences, and the farmers are becoming alarmed, and we are being cursed, criticised, and abused, some saying that we ought to be prosecuted.

There are scattering plants of the clover over a great deal more territory than that which I have spoken of as being well set; but that we have cut out mostly with hoes; some of the more thickly set places I have mowed, and then broken the ground with the plow. Whether that will kill it is a question. Some say the seed will lie in the ground for years, and then come up.

I am very sorry that I was instrumental in introducing something that is so unwelcome as sweet clover seems to be to the farmers here. I also own and manage a farm myself; but I do not care so much on my own account as I do for the ill feeling which it has caused among my neighbors.

Any information on this subject as to what extent I am responsible, or what I should do to kill it out, is what I wish.

Geo. W. Fair.

Chrisman, Ill., June 28.

My good friend, you and your neighbors are certainly making a big mistake. I have studied sweet clover all over the State of Ohio and in other States, but I have never yet found it in pasture lots, in meadows, or in cultivated fields.

I can not see why it should be called a noxious weed any more than common red clover, unless it is that horses and cattle must learn to eat it before they take to it as readily as they do to red clover. But this is not at all strange, for cattle in Florida will not eat *corn* until they have been taught. Sweet clover is in our neighborhood, along the roads, as high as the fences, but nowhere else. It grows on the dry hard clay banks by the sides of the railroads, where no other weed can find a foothold; but my richly cultivated ground is also right along by the railroad, just over the fence, and yet our boys will tell you they never find sweet clover as a weed anywhere. If you and your friends will cut your clover when it is knee-high, or a little more, you will find it will make excellent hay; and if it were really desirable to banish it from the roadsides, the matter is easily accomplished by cutting it off before it goes to seed. Teach your neighbors to use this valuable clover, and all prejudice will soon disappear. Put a fence around it and turn the cattle right in—that is, if cattle are not permitted on the roadside—and see how quickly it will disappear. If you want the ground for other crops, turn it under with a chain as you would ordinary red clover, and you will find it worth as much as or more than any other clover known, as a fertilizer.

Pass this journal around to your neighbors and I will send you more, or I will have some slips printed, to be handed out free of charge, if nothing else will cure this prejudice. I am surprised that you say nothing in regard to its value as feed, for I am convinced that some of your horses and cattle have already acquired a taste for it and a liking for it; and their "opinion" in the matter is certainly unbiased. I do not know why in the world you should go to the trouble of trying to cut off the thick old stalks with a hoe. If you really want to get rid of it, wait till next spring, when the old stalks will all be dead and gone; then plow under, pasture off, or cut the young shoots before they get too far along to be tough and hard. I can not believe the seed will lie in the ground for years; for if it did it would surely trouble us among our crops. We have between 15 and 20 acres under cultivation, and sweet clover is growing high and rampant all around my cultivated fields. Yes, it is at this writing, July 6, six feet or more, and has been growing so for years past, though we never find it in our strawberries at all, while other weeds are a terrible nuisance just about fruiting time. In traveling I have talked with others, and asked questions in regard to the habits of the plant; but I have nowhere seen it behave any differently from what it does here in Medina.

#### PUDDLING SWEET-POTATO (AND OTHER) PLANTS.

*Friend Root*.—I was in another part of the county a few days ago, and saw people there planting (or, rather, setting) sweet-potato slips. They do not use any water at all, and plant at any time during the day. Instead of watering they make a bucket of very thin mud and dip the roots of the plants in it when planting. They claim that the method is as sure as watering, and much cheaper. The only condition is that the plants should be raised in an open bed so that they may be rather tough. Those raised under glass would not do.

#### KILLING WEED SEEDS BY FERMENTATION.

You undoubtedly have had considerable trouble with weeds coming from the seeds in the manure you buy from the livery stables. You may avoid the trouble by having the manure thoroughly fermented before using it. Have it put in heaps as large as possible, in a hollow cemented or well-paved floor. You may mix dead leaves, straw, rich dirt, or any thing you wish. Have it thoroughly watered twice a week, enough to prevent it from burning, and make it rot thoroughly. The surplus water that will seep through must be received in a

hole or cistern, and pumped over the heap again unless you prefer to use it for irrigating purposes.

It is difficult to explain how it is, but the fact remains that the manure thus treated improves considerably in fertilizing value—it is estimated 100 per cent, or about; and, furthermore, the heat therein developed kills all the weed seeds and an immense quantity of noxious insects and other plant-disease germs.

In Switzerland, Belgium, and most parts of other well-cultivated countries of Europe, no manure is used without having gone through this process, which takes about three months. Another advantage is that the manure thus thoroughly rotted does not burn the vegetation in dry weather as the fresh manure invariably does. ADRIAN GETAZ, Knoxville, Tenn.

Your suggestions are both good, friend G. Instead of using mud, however, for puddling the roots of the plants, a good many use a mixture of cow manure and dirt. In regard to fermenting manure to kill weed seeds, we have practiced this for years; in fact, we had a cistern made to catch the liquid manure, and a pump to pump it on the heap. The process is given in a little book sold by the O. Judd Co., entitled "Baumer's Method of Making Manure." It works all right, and the manure is all that is claimed for it, but it is an awful sight of work. We could not afford to ferment manure in this way for farm crops, nor even for garden crops, at ordinary prices. For making potting soil for florists, or for beds in intensive gardening, it is all right. If worked properly, the compost, when finished, is very much like the manure we find under old stables. Whenever I find where an old barn has been moved away, or where a manure-heap has remained for years, so as to be thoroughly rotted, I am willing to pay a good price for the fine compost. Another thing, the average American gardener does not take kindly to this working over manure-heaps. We have to get an old gardener from some of the old countries to work at it. For high-pressure gardening there is no question but it will pay. But we get into a fashion of rushing things so much that it is hard to take the time and trouble to prepare plenty of good old rich compost; and for many crops and purposes, manure just as it is taken from the stables answers very well. For spinach, lettuce, or any other crop where strong foliage is needed, fresh manure, just as it is dropped in the stables, seems to be even better. There has been some dispute as to whether all kinds of weed seeds are killed by the fermenting process; and I believe there has been a government bulletin issued on the whole subject.

#### ONIONS FOR WINTERING OVER IN THE OPEN GROUND.

The Whittaker onion did not stand the climate here, as they were all dead this spring. The Pearl, that I experimented with here, winter-killed also, but the Egyptian did nicely, and I shall want 2 or 3 bushels this fall. I wish you would give me your mode of culture of the White Multipliers; they do the best with me. A. P. JONES.

Brandou, Vt.

We manage the White Multipliers exactly as we do the potato onions. Plant them at about the time that farmers are sowing their wheat. They make quite a little growth by fall, and, as a rule, winter without any loss. This spring we have had our first trouble by their showing seed-stalks. We never had a seed-stalk on a White Multiplier before, and did not know it was possible. The only reason I can give is that we put them out earlier than usual last fall, and they made an exceedingly strong growth; but why this should put it into their heads to send up seed-stalks when they never grow seed at all (at least I did not know they did) is more than I can tell. We hoe and culti-

vate all of these winter onions in the spring, exactly as we would any onions; and the Breed weeder is just the thing for them after you once get the surface fined up soft and mellow. At present writing, June 16th, all of our onions that were wintered out are beginning to show signs of maturity.

**HALF PRICE.**

After June 10th we sell eggs from all our yards at HALF PRICE (\$1 per 15). Eggs will be from our best pens, and handled with the same care early orders receive. Our breeds:

Barred & White Pl. Rocks, Lt. Brahmas, Langshans, Bf. Cochins, White Wyandots, Brown & Buff Leghorns, Pekin Ducks.

Our stock will surely please you; order now.

**POULTRY SUPPLIES.**

We are America's Headquarters. Biggest Stock, Lowest Prices, Quick Shipments.

NISSLY'S POULTRY ANNUAL and catalogue of "EVERYTHING FOR THE POULTRY YARD" is a book of 80 6x9 pages, finely illustrated and full of information. The book is FREE TO ALL, but we request a 2c stamp for postage.

GEO. J. NISSLY, Saline, Mich.

**AGENTS' OUTFIT FREE.** No Capital Needed. Weekly sales pay big money. We make a high grade as low as \$21.00. Fully guaranteed. Shipped anywhere on approval, direct from our factory. **ALPINE CYCLE CO., Dept. 144, Cincinnati, O.**

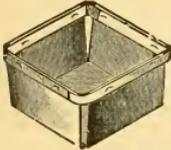

In writing advertisers please mention GLEANINGS.

**Fruit Packages of all Kinds,**

also

**Bee-keepers' Supplies.**

Order your supplies now before the busy season catches you. Price list free. Address

**BERLIN FRUIT-BOX CO., Berlin Heights, Erie Co., Ohio.**

**Queens Given Away.**

Gray Carniolans and Golden Italians. We will give a fine tested queen (either race) to all customers ordering 6 untested queens, and a fine select tested queen to all who order 12 untested queens at one time. The queens given away will be sent to customers in August.

H. R. BOARDMAN, East Townsend, Ohio.

**QUEENS.** Either 3 or 5 banded, 60 cents each; 6 for \$3.00. Nuclei and supplies cheap. CHAS. H. THIES, Steelville, Ill.

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

### THE THREE NEW STRAWBERRIES—CARRIE, DARLING, AND EARLIEST.

When I gave prices on page 502, last issue, on these three plants, I overlooked the fact that, when I purchased them from Thompson & Sons, Rio Vista, Va., I was restricted, in offering them, to their prices. The Darling was a present to me, and under the circumstances it would ill become me to offer them for sale at less than their prices. In view of this, our prices for the future will be \$2.00 per dozen for Carrie and Earliest; \$3.00 per dozen for Darling. At the above price you may have potted plants by express or layer plants postpaid by mail. Earliest and Darling show such wonderful vigor that they have gone right through our severe drouth without any watering up to date, July 9; and we have, from our original half-dozen plants in September last, something like 100 fairly well-rooted. Of course, I can not tell how the Darling and Earliest may turn out with a more extended trial out in the field; but I am satisfied that, for extra early, they are going to be of great value. Carrie has been already sufficiently tested to warrant it a place, and the testimonials in its favor from our Ohio Experiment Station are enough to induce all strawberry-growers to give it a trial.

SOLD OUT.

We are sorry to say that, at present writing, we are sold out of both Carrie and Nick Ohmer. We are going to try hard, by the use of water and shading, to increase our stock so we can offer them again later, but we can not tell you how we shall succeed. We can furnish you all the rest mentioned on page 502 of our previous issue.

### PRICES OF GARDEN PRODUCTS, JULY 15.

Wax beans are bringing 8 cts. per qt., all we can pick; early beets, 5 cts. per bunch weighing a pound, and the demand is greater than the supply. Early cabbage is 5 cts. per lb.; cauliflower the same; lettuce the same, demand good. Bunch onions, American Pearl, 5 cts. a 1-lb. bunch; demand beyond the supply; White Multiplier, ditto. American Wonder and Gem peas bring 5 cts. per quart; Stratagem, 8 cts. Runishes, when we have any, 5 cts. per bunch. Tomatoes, 5 cts. a qt. These are just beginning to ripen in our greenhouses. New potatoes are \$1.00 per bushel, and the demand is beyond the supply. The above are all retail prices, where things are taken around to the houses every morning. Black raspberries bring 10 cts. per qt.; red ones bring from 12 to 14; currants, \$1.00 per ½ bushel; gooseberries, 5 cts. a quart—slow sale.

### NEW-CROP SEEDS AND PLANTS FOR SALE JULY 15.

First we have crimson clover of our own growing; but as the supply is limited and the demand large it will probably soon be gone; but we have engaged a large stock of home-grown new crop, and expect to be able to ship promptly during the whole season.

We have a great lot of strawberries getting rooted; but they are hardly sufficiently established to send out just now—at least not very many of them.

Winter onion-sets are just ready to gather, and now is the best time to plant them. Price 5 cts. per qt.; peck, 35 cts.; bush., \$1.00. Whittaker onions, large size, qt., 10 cts.; peck, 75 cts.; bush., \$2.50; small ones, qt., 18 cts.; peck, \$1.25; bush., \$4.00. This is the only onion that I know of that never sends up a seed-stalk. It really does not know how, and I am greatly in hopes it will never learn. The onions are great whoppers, and will keep better than any other onion I know of, unless it is the White Multiplier.

We have White Multipliers now, quite hard and firm, that were harvested a year ago; but this onion has for the first time this summer sent up seed-stalks. We have carefully "rogued" our onions that tried to send up a seed-stalk, and these are to be cooked (not sold for seed) so as to discourage the trait. White Multiplier is the same price as the Whittaker. I can think of no reason why our White Multipliers have sent up seed-stalks this season unless it is that they were planted rather earlier last season, and made quite a growth before winter. You know the season was very wet, and hence we

had an unusual fall growth. Our American Pearl onion-sets will be ready to gather by the first of August. The price will be 20 cts. a quart; peck, \$1.00; bushel, \$3.50. If somebody else offers genuine American Pearl sets, *true to name*, any cheaper, we will make lower prices, and we will also make a rebate to anybody who has paid us a larger price. All of these onions are to be planted out in September. With plenty of wet the Multipliers may be planted now, and they can be taken up and divided and set again in September or October. I do not know why these beautiful Multipliers and potato onions are not more extensively used for the table. They are certainly easy to grow and easy to keep—at least in our locality.

### TIME TO SOW BUCKWHEAT.

Please note our very low prices this season—a two-bushel bag for only \$1.10. Sow from half a bushel to three pecks per acre. If the ground is good, half a bushel is plenty. The later the crop the better the yield, providing it does not get nipped by the frost. The heads fill much better in cold weather than in hot. In most localities it is usually safe if sown any time before the first of August.

When potatoes are bringing a dollar a bushel, don't let the bugs eat up the vines. Get up at daylight, when the dew is on, and dust them with a very little Paris green.

### CONVENTION NOTICE.

MR. EDITOR—The next annual convention of the United States Bee-keepers' Union will be held, in the main hall of Catton's Business College, corner of Main and Huron Sts., Buffalo, N. Y., commencing at 10 o'clock A. M., August 24th next, and closing on the afternoon of the 26th.

Papers are to be read by W. G. Hutchinson, R. F. Holtermann, E. Whitcomb, Hon. R. L. Taylor, Mrs. L. Harrison, R. C. Aikin, G. M. Doolittle, Dr. J. P. H. Brown, Hon. Eugene Secor, G. W. Brodbeck, M. B. Holmes, A. E. Mannin, E. W. Custer, and P. B. Elwood will be added the President's Address; and perhaps the General Manager and the Secretary may have something of interest to present.

The programs are now printed, and are in the hands of the Secretary. There are six bee-keepers' songs, with music, in the program, and abundance of time is allotted to the discussion of all papers, and for the asking and answering of questions.

Any one not a member of the Union can have a program sent him by mail on receipt of 5 cents in stamps, by the Secretary.

Several of our well-known bee-keepers, such as A. I. Root, Dr. Miller, S. T. Pettit, and others, who are not on the program, will be present to help make the convention interesting and instructive.

It is probable that suggestions will be made at this convention in the line of so amending the constitution of the Union as to remove all objectionable features and add such other provisions as may seem desirable; and suggestions in this line by those not able to be at the convention can be sent to the Secretary, to be brought before it. Some suggestions have already been received by the Secretary, and others have been made in the newspapers.

Those going to the convention should buy round-trip tickets to the Grand Army of the Republic encampment (not to the United States bee-keepers' convention), which meets in Buffalo during the last week of August. The G. A. R. have secured a rate of one cent a mile each way in the territory of the Central Passenger Committee, which is included by Toronto, Canada, thence on a line to Port Huron, Mich.; all of the southern peninsula of Mich.; Chicago, Peoria, and Quincy, Ill.; St. Louis, Mo.; Louisville, Ky., and Pittsburg, Pa. The Western Passenger Association and the Trunk Line Association make a rate of one fare for the round trip in their territory, to places in the Central Passenger Association, from which point the fare will be one cent a mile each way; but tickets must be purchased to Buffalo from the starting-point. Inquire of your ticket or station agent in all territory out-side of those named above for rate and the time the tickets are good for. I have been unable to learn the rates in such territory, but presume they will be the same as those of the Western Passenger and the Trunk Line Association; but be sure to inquire of your ticket agent, as above suggested.

In the Central Passenger and Trunk Line territory, tickets will be good going Aug. 21, 22, and 23; and, if vised at Buffalo, will be good, returning, for 30 days.

Mr. O. L. Hershiser, of Buffalo, has charge of arrangements at Buffalo, and will attend to the matter of hotel rates. Mr. H. writes: "I purpose obtaining accommodations in private families for all bee-keepers who prefer such to hotels." Members of the Union can learn in regard to hotel rates by applying to the Secretary at the place of meeting. If known in time, hotel rates will be given in the bee periodicals.

A. B. MASON, Sec., Station B, Toledo, O.

## For Sale.—Bees and Queens.

Queens 50 cts.; nucleus, two-frame, with queen, \$1.50; one-frame, \$1.00; three-frame, \$2.00.

Mrs. A. S. Simpson, Swarts, Pa.

## If You Want Queens By Return Mail,

Bred in full colonies, from the very best honey-gathering strains in America, crossed with drones from a different mother to avoid inbreeding, send in your orders at once.

In writing advertisers please mention this paper

### QUEENS BY RETURN MAIL.

Daughters of best imported queen mother, warranted purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded. **L. H. ROBEBY, Worthington, W. Va.**

### Second-hand Bicycles in Trade for Honey or Beeswax.

One '95 Victor, 24-inch frame, 64 gear, Morgan & Wright tires, in good running order, weight 28 lbs., \$18.00. One ladies' Monarch, '94 pattern, Morgan & Wright tires, wood handle-bars, in good running order, weight 33 lbs., \$15.00. One girl's wheel, '90 pattern, 24-inch wheels, cushion tires, \$4.00. Will take white honey or beeswax at market quotations. Fuller particulars furnished upon application.

**THE A. I. ROOT CO., Medina, Ohio.**

### DRAWN FOUNDATION.

Finally we have our dies completed  $\frac{3}{4}$ , and in operation, making drawn foundation. We find that our hydraulic machinery for operating the dies is inadequate to the pressure for using the dies full size, and we are making pieces 4x4, just right to fill a section; and until we get more powerful machinery we are not prepared to furnish it larger nor in very large quantities, but such as we can furnish will be much superior to samples from the former dies—lighter and more delicate. It is already too late to test it in the production of early honey; but the tests on a late honey crop, which generally comes in more slowly, will be more severe.

We offer the drawn foundation in  $\frac{1}{2}$ -lb. packages at 75 cts. with other goods, or 90 cts. prepaid; three pieces, 4x4, to fill a section, for 10 cts.; by mail, 12 cts.; 24 pieces, 50 cts.; by mail 60 cts.; 10 pieces, 25 cts.; by mail, 30 cts. If you have prejudices or preconceived notions in regard to this drawn foundation, send for a sample from the last dies and see it and test it for yourself, and then you will be able to speak intelligently in regard to it. It is not too late to test it this season in very many localities.

**THE A. I. ROOT CO., Medina, O.**

Extracted white clover, new, in small or large quantities cheap. Said honey is water-white, and very thick; in fact, a No. 1 article.

**J. B. MURRAY, Ada, Ohio.**

### The Adels, The Adels!

"Sammonsville, N. Y., June 21, 1897.  
"Find \$5.50 for queens. The best stock in 1896 out of 130 was an Adel. The best stock this year out of 165 is an Adel from an 1896 queen from you."

## Root's Goods at his prices in Northern Michigan.

Local dealers supplied at dealer's rates. Goods shipped from Mt. Pleasant, Coleman, or Evart.

~~~~~ **B. WALKER, Evart, Mich.** ~~~~~

## Gleanings at Reduced Rates.

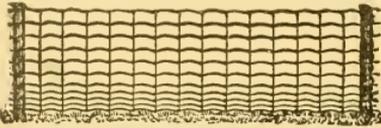

With a view to encouraging membership to all kinds of bee-keepers' associations whatsoever, local or otherwise, we have decided to offer **Gleanings** at 75 cts. per name to members of such organizations. Old or new subscribers may take advantage of this offer; but in the case of the old, all back subscriptions must be paid up before the 75-cent rate for a year will be allowed; otherwise only 9 months will be credited.

We must either require all subscriptions at this reduced rate to come through the secretary, or we must have evidence of some sort that you belong to some bee-keepers' society. Simply a line from the secretary, stating that you are a member in regular standing, will suffice. At your next annual meeting, bear this in mind; and if you wish to become a subscriber to this journal, hand 75 cents to your secretary, and when that amount is received by us your name will be placed on our subscription list for 12 months.

If you do not now belong to any association, send \$1.75 to us or to Secretary Dr. A. B. Mason, of the United States Bee-keepers' Union, at Toledo, Ohio, Station B. This will entitle you to a year's membership and protection in the Union, and one year's subscription to this journal.

The A. I. Root Company,  
Medina, Ohio.

**STORRS & HARRISON CO.,**  
Box 331 Painesville, Ohio.

## Ajax Bicycles. Price only \$35.

We have sold a large number of these bicycles, and they are giving universal satisfaction. For instance, the following letters will explain:

"The Ajax bicycle arrived Saturday in good condition. It is entirely satisfactory in every respect. It is a handsome and easy-running wheel, and has the appearance of one put up for service.

FRANK WRIGHT."

"Laporte, Mich., June 28, 1897.

"The Ajax wheel, Model 37, with baby carrier (Kalamazoo) came all right, and it is really better than I expected; although I have learned that when 'The A. I. Root Co. say a thing is first-class it is as represented.

THOS. M. TODD."

Payson, Utah, July 8.

We have so much confidence in these wheels that three of them have been and are now in use in the Root firm; and E. R. Root expects to make his bicycle-tour on one of these through the East this summer. They are up to date, have large tubing, wood reversible handle-bars, Morgan & Wright double-tube or single-tube tires, with option of gearing and option of height of frames, and a choice of finish.

We will sell these wheels and take in trade beeswax or first-quality honey at market prices. We have only a few in stock; and after those we have on hand are gone we will not dispose of more in trade.

A beautiful catalog, showing these wheels up in full, sent on application.

Next Annual Meeting at Buffalo, N. Y., Aug. 24—26, 1897.

Honey Column.

CITY MARKETS.

NEW YORK.—Very little comb honey on our market. Some demand for white comb at 10@11. Extracted arriving quite freely; market rather weak; common light the last few days. Southern average, common grade, 50¢ per gal.; better quality, 55@60. Beeswax, some demand at 26@27. FRANCIS H. LEGGETT & Co., Franklin and Varick Sts., N. Y.

MINNEAPOLIS.—Fancy white comb honey, 12@14; fancy amber, 10@11; No. 1 white, 11@12. Extracted, white, 6@7; dark, 4@5. Beeswax, 24@27. Stuff moving very slowly. S. H. HALL & Co., Minneapolis, Minn.

ALBANY.—We have received no new comb honey as yet, but have advices of some on the way. It is too early to say much about prices. The crop in this State promises to be a good one; but on a recent trip through Vermont the producers claim that the outlook is poor. We still have a few cases of old honey which is going off slowly at 5@6c. Nothing doing in extracted. CHAS. McCULLOCH & Co., Albany, N. Y.

CINCINNATI.—There is a fair demand for extracted and comb honey. We have already disposed of quite a number of arrivals of fine quality. We quote 11½@13 cts. per lb. as the range for choice white comb honey, and 3½@6, according to quality, for extracted. Demand for beeswax is fair at 22@25 for good to choice yellow. CHAS. F. MUTH & SON, Cincinnati, O.

CHICAGO.—Some few lots of the new crop of white comb have come on to the market and sold at 12 cts. Lots not strictly nice may fail to bring this figure. Very little sale for extracted honey of any kind. Prices range from 5@6 for white, 4@5 for amber, and 3½ for dark. Beeswax steady at 26@27. R. A. BURNETT & Co., 163 South Water St., Chicago, Ill.

DETROIT.—White comb honey (new), 10@11; no dark offered. Extracted, white, 5. Beeswax, 25@26. M. H. HUNT, Bell Branch, Mich.

MILWAUKEE.—The demand for honey has not been very good here since our last. The receipts of new extracted have begun to arrive, which is much earlier than known for many years. The quality of some is not up to the standard, being thin, and lacking flavor. Market is almost nominal. Can quote choice white 1-lb. sections, 12@13; fair, 8@11. Extracted in barrels, white, 5½@6; in cans and pails, 5½@6; dark, 4@4½. Beeswax, 25@27. A. V. BISHOP & Co., Milwaukee, Wis.

COLUMBUS.—New white clover, 12½@13; old dark, 7@7½. Very fair demand for white-clover honey at above prices.

THE COLUMBUS COMMISSION & CO., 409-413 N. High St., Columbus, O.

NEW YORK.—The condition of our market remains about the same. We have some call for white comb honey at 10@12, according to quality. Market on extracted rather weak owing to the increasing supply and faint demand. We quote Southern 50@55 per gal.; California light amber, 4½@5; California white, 5@5½. Beeswax remains steady and in good demand at 26@27. HILDRETH BROS. & SEGELKEN, 120-122 W. Broadway, N. Y.

DENVER.—We quote our honey market as follows: Fancy white, 11; No. 1 white, 10; No. 1 white extracted, 9½@10. The honey crop for Colorado promises to be very large and prices low.

R. K. & J. C. FRISBEE, Lock box 1014, Denver, Col.

PHILADELPHIA.—Extracted honey arriving freely; also some very nice comb. Honey-buyers are slow to take hold, as they are looking for low prices, and are holding back for large arrivals later on. We quote No. 1 comb white, 10; fancy comb, 11@12; extracted amber, 4; white extracted, 5@5½. We are producers of honey, and do not handle on commission.

WM. A. SELSER, 10 Vine St., Philadelphia, Pa.

KANSAS CITY.—The new crop of comb and extracted arriving, but the demand is very light; weather too hot; vegetables and fruit too plentiful. We quote No. 1 white, 1-lb. comb, 12@13; No. 1 amber, 11@12; No. 2 white, 10@11; No. 2 amber, 9@10; extracted white, 5@5½; amber, 4½@5; dark, 3½@4; beeswax, 25@30. C. C. CLEMONS & Co., Kansas City, Mo.

ST. LOUIS.—Fancy white comb, 12@12½; Nos. 1 and 2 white comb, 10½@11½; dark to amber, 7@9; extracted white, 4½@5½; amber, 4½@4½; dark, 3½@4. Beeswax, prime, 24@24½; dark, less. Since last quotations we have sold 4500 lbs. extracted amber honey at 4½. Our reports show a large crop of honey this season, but on account of high prices on sugar we look for a good manufacturing demand for honey, which is now taking hold. WESTCOTT COMMISSION CO., 213 Market St., St. Louis, Mo.

CLEVELAND.—Old honey.—Fancy white, 11@12; No. 1 white, 10; fancy amber, 8; buckwheat, 7. Our first shipment of new honey just arrived, selling at 13 cts. No demand for old honey; however, we believe new honey is going to sell fairly well. A. B. WILLIAMS & Co., 80-82 Broadway, Cleveland, Ohio.

FOR SALE.—Fancy extracted in 60-lb. cans, and fancy comb (Danzy sections) mangoe honey in 30-lb. cases. Cash offers wanted, f. o. b. here. H. PRICE WILLIAMS, Miami, Florida.

CHOICE CALIFORNIA EXTRACTED HONEY.

Soon after this number goes to press we expect to receive a carload of very fine water-white and light-amber honey from M. H. Mendelsohn, of Southern California. This honey is of exceedingly fine quality, very thick, and of special value to those who put up honey in glass to retail, because it does not granulate. It is in new 60-lb. cans, and we offer the water-white at 6½¢ per lb. by the case of two cans. Light amber, which is whiter than most eastern honey at 6¢. In larger lots we can make lower prices. Samples and further particulars to intending purchasers on application. THE A. I. ROOT CO., Medina, O.

# A Tested Queen and the Review for \$1.50.

I have a large number of nuclei containing fine tested Italian queens of this year's rearing, and have decided to use them in helping to build up the circulation of the **Review**; hence offer a queen and the **Review** one year to *new* subscribers for only \$1.50. **Review** alone, \$1.00; queen alone, \$1.00. If several queens are wanted, write, and the price will be made according to the number. As a rule, orders are filled by return mail, and there is never a delay of more than three or four days, and that on large orders.

W. Z. HUTCHINSON, Flint, Mich.

## Honey Leaflet

Dr. C. C. Miller.

Why honey is more wholesome than cane sugar.

Honey as an article of diet; honey cooking recipes.

This leaflet is written for the benefit of consumers, and is put out at an extremely low price so that honey-producers may distribute them free to their customers. Prices: 10, 5c; 100, 20c; 500, 75c, all postpaid; 1000, 75c, carriage extra.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer I write for a circular. I do not think the 4-inch Smoke Engine too large.

January 27, 1897.

Truly, W. H. EAGERTY, Cuba, Kansas.

Bingham & Hetherington Uncapping-knife.

T. F. BINGHAM, Farwell, Michigan.

## A Penny Saved is a Penny Earned.

Yes, it's better than that, for the saved penny you don't have to earn twice. Well, the **Weekly American Bee Journal** will help you save your pennies. It is a real money-saver to the bee-keeper who will read and practice its teachings. The regular price is \$1.00 a year, or only about two cents per copy. But in order that *new* readers may give it a trial we will send it for **only 50 cents from the time we receive your subscription to the end of 1897**. Now, the sooner you send the half-dollar, the more copies you will receive. Send 1c stamps if more convenient. Sample copy free.

GEO. W. YORK & CO., 118 Michigan St., Chicago, Ill.

### STRAY STRAWS

FROM DR. C. C. MILLER.

MR. HARBISON has set out a large plantation of the black (or ball) sage, and finds the profits exceedingly large.—*Prof. Cook, in American Bee Journal.*

MR. EDITOR, on p. 525 you speak in what seems a commendatory way of replacing brood-combs with foundation when the combs become dark. Do you really mean that?

POPE LEO calls honey "that celestial gift." [The pope is right. No other sweet, pure and simple, can be used for direct consumption without some special manipulation on the part of man.—ED.]

SOME POINTS given in "Musings," p. 514, confirm the opinion that, the ripener and thicker honey is, the less inclined to granulate; and yet it is sometimes insisted that thickening hastens granulation.

HONEY-SALVE is recommended by Dr. Kneipp as an excellent dressing for sores and boils. Take equal parts honey and flour, add a little water, and stir thoroughly together. Don't make too thin.

THE *Southland Queen* reports Dr. Stell, in Mexico, getting \$1 a section for honey, a total of \$1750 from ten colonies. Even cutting that in two to make it American money, it makes \$87.50 per colony. Not so bad.

THE *Leipziger Bienenzeitung* cites a case to prove that bees gnaw wax from old combs and carry it into the hive on their legs. I think that is nothing uncommon; but is such wax ever used except as a substitute for propolis?

J. F. MCINTYRE keeps his 600 colonies of bees in one apiary, says Prof. Cook, in *American Bee Journal*. What can't they do in California? [This is remarkable. In most localities in the Northern States, 125 colonies at the most would be too many.—ED.]

THE ANTICIPATION of a big crop everywhere because white clover is so plentiful is likely to amount to a scare. When the total honey crop is footed up, I doubt whether the figures

will be as large as a good many are now anticipating. [I am beginning to think the crop is not going to be as large as we at first expected. See editorial on this point in another column.—ED.]

I DON'T KNOW of a man in the ranks of beekeepers to whom will go out more kindly wishes from all for a happy outcome of his recent matrimonial venture than to my dear friend Prof. Cook. Blessings on his head. [You are right, doctor. GLEANINGS wishes the professor blessings and joy.—ED.]

PFARRER FLEISCHMANN put a thermometer in 8 different colonies in winter, and found a different temperature in each. The thermometer rose 6° to 8° on feeding, but settled back to its former place in a few hours. [Doctor, why didn't you tell what the temperature was in the cluster during winter? I suppose it was somewhere about 70 Fahr.—that is, in the very center of the cluster itself.—ED.]

HAVING REPORTED that I never saw laying queens fight, I thought I'd give the matter a severe test. The other Saturday I put six queens in one cage. They seemed to quarrel more or less throughout the day, but in the evening all appeared alive and well. On Monday morning, however, one lone queen was left to tell the tale. [This is interesting. And now the question arises, Was the sole survivor the fittest? She doubtless was the survival of the strongest.—ED.]

IT'S NOT WONDERFUL that, in a certain location, white clover should be more plentiful in 1897 than ever before. But it is decidedly remarkable that this should be so generally the case all over. Wonder why. [Yes, why? We can only guess that the abundance of rain, and cool weather in the early spring, had something to do with it. But after all, this does not entirely explain it, because we have had cool wet springs before, without a remarkable showing of clover following.—ED.]

BOTTOM STARTERS at Medina, you say, Mr. Editor, were about ½ inch. My bees are more inclined to tear down such narrow starters; ⅜ deep are more respected, and I'm not sure they curl worse. But I'm rather expecting to use drawn foundation for bottom starters, even at the present high price; ½ inch of that might work all right. [A great

many of our half-inch bottom starters did curl over. If they had been  $\frac{3}{4}$  inch I am afraid they all would have done so. Perhaps our foundation was *too* light.—Ed.]

DO YOU REMEMBER how some vigorously protested that wired brood-combs would be a failure, and challenged the production of a single wired comb with brood all over the wires? It makes one smile after seeing hundreds of such combs, and I'm wondering a little whether some of the protests against drawn foundation will not turn out the same way. [When the wiring of combs was first talked of it was before my day in active bee culture; but I have no doubt that what you say regarding it is true. Why will human nature be so obtuse and contrary?—Ed.]

A LUBRICANT by B. Rietsche is as follows: Put 2 oz. soft soap in a little sack. Stir the sack in 5 quarts of warm water till the soap is dissolved, then add 5 quarts cold water. The plates of the Rietsche press are plunged into this liquid, and by this means 150 sheets of foundation are now made in an hour. I should want section foundation well rinsed. [If the Rietsche press must be immersed in a fluid every time a sheet has to be taken from it, I should question very much whether there is more than one man in the world who could get off anywhere near 150 sheets per hour.—Ed.]

J. B. GRIFFIN writes that foundation was shipped to Georgia from Medina, and the paper slipped to one side, leaving a margin of  $\frac{3}{4}$  inch without paper. The papered part was all right, but that  $\frac{3}{4}$  inch was one solid piece 8 inches thick. That settles it that foundation must be papered to stand great heat in shipment. The time of year may have something to do with it. But I'd feel safer with the paper for the South. [I have been talking with young Louis Dadant, of Dadant & Son, regarding the advisability of leaving paper out of foundation. He shook his head very decidedly, adding that they could never think of doing it. We never considered the matter seriously, any more than to hold ourselves in readiness to ship without paper to those who specifically requested it.—Ed.]

DID YOU ever notice that an old black comb will start robbing much sooner than a snow-white section? In a harvest, when you can safely leave a super of sections exposed all day long, it isn't best to have brood-combs standing around. [I for one never noticed that old black comb would start robbing quicker than honey in sections; but I have noticed that honey and brood together would start the bees much quicker than either alone; and when once started the bees are far crosser than when robbing from honey alone. I have observed, also, that the mutilation of brood, for instance the uncapping from drone brood, very often makes the bees decidedly savage. When destroying drone brood I am careful to have the smoker well going, and work rapidly enough to prevent bees robbing.—Ed.]

A SECOND STORY of brood-frames filled with foundation was put over colony No. 63, so the queen could occupy it for brood. Instead of

that I found eight frames of honey sealed solid from top to bottom. I said, "I'll have that in sections." I uncapped the honey and alternated the frames of honey with the frames of brood, then put sections over. What do you think? Those pesky bees coolly sealed that honey all up again! [Without trying exactly the same experiment, I should be inclined to believe that the putting-in of the frames of foundation in alternation would have a decided tendency to cause the bees to do exactly what they did do. If it is not too late, suppose you try the experiment of leaving out frames of brood, and putting a super on top. While I do not know that they would carry the honey above, they would not, I opine, be in as great a hurry to cap it up again in the same combs.—Ed.]

I'M NOT OVERSTATING, I think, when I say the clover bloom was 50 per cent greater this year than ever before. But I'll get no crop in proportion. Two of my three apiaries have suffered from drouth. [Wherever there has been some drouth, the crop of clover honey will, of course, be diminished in proportion. There has been no drouth in this vicinity; and yesterday, July 22, when I was at the out-yard, and at Mr. Vernon Burt's also, the bees were bringing in honey heavily. A good portion of it was probably coming in from red clover; but frequent rains have seemed to give even white clover a new start. A week ago I supposed the honey season had closed, or at least it ought to have stopped; but in the mean time bees have taken supers of the drawn foundation, filled them with honey, and capped them over. Supers containing foundation only have scarcely been touched. This goes to show that the flow from clover is light.—Ed.]

O. O. POPPLETON rightly objects, p. 517, to wide bottom-bars with a space between comb and bottom-bar. But I'm getting my combs built down solid to the bottom-bar, and so far am well pleased with bottom-bars  $1\frac{1}{2}$  wide. I've been told that, in time, the bees will dig out a space between comb and bottom-bar—a prophecy which I'm hoping may turn out to be false. [I do not know but you may think I am fickle; but since the question of wide and narrow bottom-bars has been brought up I have been watching the matter very closely. In answer to a correspondent in another column I expressed myself as believing that it was a mistake to change from narrow  $\frac{3}{8}$  bottom-bars to wider ones, but at the same time admitted that the one objection to the narrow bars was that the bees would build clear past them to the first set of frames below. Well, yesterday, July 22, when I was at the out-apiary I took hold of an extracting-super, eight-frame, full-depth, and attempted to lift it off the hive. To my surprise it seemed to be fastened down with burr-combs. I tugged and pulled until I got it loose. Quite by accident half the frames on the one side of the super contained *narrow* bottom-bars, and the other half were regular  $\frac{3}{8}$ -inch-wide bottom-bars. Examination showed that burr-combs had been attached to every one of the frames first mentioned; but there was not a burr-

comb under the other half of the super where there were bottom-bars  $\frac{3}{4}$  inch wide, and yet the combs were built clear down to them. In case of the narrow bars, the bees had extended the combs clear past them, and attached them solidly to the top-bars of the frames below.—Ed.]

### GRADING HONEY.

Defects of the Washington Grading, Chicago Grading, and the Gradings Recently Proposed in Gleanings.

BY B. WALKER.

*Friend Ernest*.—I see from the last issue of GLEANINGS that the matter of grading honey is once more up for discussion, with a view of reaching a speedy solution. Fearing that undue weight has been given to the changes I have proposed, as you have in your final comments stated so kindly and yet so emphatically, and believing that no set of rules ought to be adopted that would fail of receiving our approval, and as both you and Dr. Miller seemed inclined to favor, in the main, the proposed changes, and as I must say that neither set of rules as modified would be sanctioned by me, and realizing that it is very important that no serious mistake be made at this time, I am impelled to ask another hearing.

Yes, I have a confession to make and an explanation to offer; and at the risk of being regarded as fickle-minded, not to say dishonest, I propose, with your permission, to make the one and offer the other at this time.

No, Ernest, the rules you have published as "Walker's Amended Washington Rules" do not now nor have they at any time fully set forth my views or exemplified my practice in grading honey. Do you ask why I offer them, then? I will tell you. I have been very desirous to see some change, at least, made for the better in the rules already in force; and in proposing the suggested alterations, like an old-party politician preparing his platform, rather than a "*dyed-in-the-wool*" third-party man of thirty years' standing, who has never once allowed expediency to stand in the way of principle in matters political, I weakly allowed myself to offer such changes as I considered would stand at least some show of being adopted. Still, bear in mind what friend Hutchinson had to say of the Washington rules, and the weight you had given his views at the time; and not forgetting that, at the time of the adoption of the original rules for grading at the Chicago convention, the requirements of which were far more exacting than the Washington rules, when, as a member of the committee for preparing these rules, I was not even allowed to read to the convention those I had drawn up for its consideration, and recalling, too, that when, a little later on, the rules prepared by friend Baldrige were rushed through the convention (my vote being the only dissenting one), I had the temerity to ask how many members of the convention

had ever really raised, graded, and marketed five thousand pounds of comb honey, I was promptly called down by the chairman of the committee on rules for grading in these terms: "We don't propose to have this convention run by one man; and I will have you to understand that we know how to grade honey, even if we don't know how to raise it."\*

Realizing, too, that the alterations I should propose were to run the gauntlet of Dr. Miller's criticism, who, as chairman of this same convention, failed to recognize the request to have my proposed rules even read,† I naturally felt reluctant to propose changes which would in all probability fail of adoption at this time. Believing now there is a real determination to adopt something practical, I wish, with your permission, to state more fully what my views and practice really are.

Right at the outset I wish to say that I agree most heartily with Miss Wilson in the view that the words "the comb unsoiled by travel-stain or otherwise" should be stricken out of the description of the fancy grade. In fact, I have not for many years past allowed a slight soiling of the comb surface only to exclude a section from the fancy grade; but at the same time I have uniformly kept such sections by themselves, and put the snow-white combs in a separate grade, which I have termed "Extra Fancy."

When snow-white combs, because of some slight defect, had to be excluded from the "Extra Fancy" grade, I have made a practice of keeping such sections in separate cases. Such cases also, in crating for shipment, and in distributing on the market, have been grouped together, so that the contrast in the color of the cappings would not attract attention.

I have found, by long experience in many different markets, that the important thing is to keep the snow-white combs separate from the slightly soiled ones, although not one grocer in a hundred or one consumer among ten thousand will ever object to the latter as not being fancy. Right here I will affirm that not one among all of the exhibits of honey at the last World's Fair—yes, I will go further, and say not one case in these exhibits that were the admiration of thousands, and that finally were awarded medals, but was open to criticism in this matter of slightly soiled combs, *if perfect in other respects*; and really that exhibit which received the highest praise of all, doubtless on account of the faultless filling, sealing, and fastening, was most deficient of all in the eyes of the expert in this one particular—"slightly soiled combs." As I had occasion to handle over section by section while grading thousands of pounds taken from different State exhibits, and was obliged to make in every instance four different grades, very little of which found a place in the extra-fancy

\* I afterward had the pleasure (with his consent) of grading this man's World's Fair exhibit, which he often referred to as the finest on the ground, into five grades according to my ideas of grading.

† It is no more than fair that I should state here that the doctor soon afterward wrote me that the slight was not an intentional one.

grade, even with my lax system of grading, I ought to know what I am talking about.

Right here it occurs to me that the only reason why friend H. did not have a single complaint against the Washington rules was because nobody ever made any practical use of them; but if anybody attempted to do so he evidently thought best to ignore them altogether, and *keep perfectly quiet*.

I can scarcely agree with Dr. Miller in the view that the even thickness of combs, with reference to the fancy grade, needs no mention; and if he will try his hand at grading a few tons out of that large portion of the crop which is raised without the use of separators, I think he will find reason to change his mind. The word "comparative" that he objects to, however, does not suit me either; but it was used as a concession to brevity. My preference is for more definite terms, even if more space is required. Neither can I see the propriety of inserting the words "outside of wood," etc., with reference to scraping free from propolis. I am aware that it is seldom that the inside of a section requires attention on this account, but occasionally clots of bee-glue on the inside of edges of sections are very noticeable, and should be removed.

In my faith and practice, not less than four grades are required in order to comprise the great bulk of marketable honey. These I have named as follows: Extra Fancy, Fancy, No. 1, No. 2.

#### EXTRA FANCY.

All sections to be well filled, combs straight, not varying in weight more than two ounces in any one shipping-case; the combs of uniform color, of nearly even thickness, firmly fastened to four sides, and unsoiled by travel-stain or otherwise; all cells sealed except the row next to the wood; sections must be new and neat.

#### FANCY.

Like Extra Fancy, except the combs may be slightly fastened to or detached from the bottom, and not perfectly straight. The entire comb surface may be *very* slightly or half of it slightly soiled; not to exceed two cells may contain bee-bread; not to exceed half a dozen may be unsealed, or contain light-amber honey, and the weights vary three ounces in any one shipping-case; sections may be slightly stained, but the wood must be reasonably neat.

#### NO. 1.

Like Fancy, only combs may be somewhat but not *very* crooked; vary in weight four ounces in a shipping-case; one-eighth part of comb contain light amber honey, an equal amount of comb surface soiled or unsealed, or the entire surface slightly soiled; half a dozen cells of bee-bread may be present, and the sections may be somewhat but not much stained or soiled with propolis.

#### NO. 2.

Like No. 1, but combs may be more crooked and uneven, and not over three-fourths filled; but any one section must weigh half as much as the heaviest section in the case. Twice as many cells of bee-bread or amber honey are

permissible; one-fourth part of the comb may contain amber honey, or an equal amount of comb surface may be unsealed or much soiled, or the entire surface considerably soiled.

Supplementary to these rules I make use of a list of defects somewhat as follows:

A slight soiling of a small portion of one side of the comb surface; a very slight soiling of one entire comb surface; half a dozen cells of light-amber honey on one side of comb near the wood, or half that number in the body of the comb; a cell of bee-bread; a couple of unsealed cells on one side of the comb inside of the outer row; comb detached, or not firmly fastened at the bottom; wood slightly stained or soiled; comb not perfectly straight in the absence of separators; a slight crack or marring of the comb surface.

The presence of any one of the above-mentioned defects in a section does not exclude it from the extra-fancy grade. In addition to those already mentioned as belonging to these grades, any two of them are to be allowed in the fancy grades, and all of them in the No. 1 grade.

Doubtless this will appear a formidable list of defects to tolerate in the fancy grades; but in actual practice, few of them are present in any one case, and, where present, are noticeable, as a rule, only to the expert.

Whether this method of grading will meet with the approval of bee-keepers, remains to be seen. It is at once evident that, if generally adopted, it will result in placing a large portion of the crop (that under present rules would find a place in No. 1 grade) in the fancy grade, while another portion will stand a show of selling at an extra price by taking rank as extra fancy.

When I tell you that I have been frequently informed by jobbers that my No. 1 honey averaged better than that they frequently bought for fancy, that my fancy grade has not failed to suit hundreds of particular customers among retail grocers, and that I have never been able to get a sufficient supply of the extra-fancy grade to meet the demands of my most exacting patrons, you will see that I for one at least have no occasion for adopting some other system at present.

I am aware that these rules will be regarded by many as altogether too prolix. At any rate, you can see that the concise ones that have been in force for four years past have been any thing but a success; and I venture the opinion that any set of rules, no matter how worded, if equally brief, will fail of being of practical use. To my mind, it is a case where mere brevity has no particular merit.

Even with the lengthy set of rules I propose, unless a 5th grade is made use of, a great deal of marketable honey will have to be thrown out; and even the expert will often be puzzled to find a place for choice honey that has no adequate description in these rules. Of course, a good deal will have to be left to each man's judgment; but where experts differ, it will be of little consequence where certain sections are placed, as no one will kick, and the difference in the outcome to the producer will be slight.

By the way, I notice you made a mistake in stating the price per pound I offered in my ad't which you were afraid to publish. It was only 25 cts. per pound, and the offer referred to the rules adopted at the Northwestern convention held at Chicago, instead of to the Washington rules, the former being the more strict in their wording. See the *Review*, Vol. V., page 18. Still, I have no doubt I should have been perfectly safe in offering \$25 instead of 25 cts. per pound for the grade described.

[Since the above was in type the following has come to hand.—ED.]

I find that, in my hurry to have my letter on grading reach you last week, I have overlooked several important points which I wish to mention. As the rules are intended for use in grading honey of all shades of color, it will not answer to use the terms "light amber" or "amber" as though they were describing defects; therefore the words, "next darker in color," should be substituted wherever I have used these terms.

Again, three terms are not enough to properly designate color in the different grades. There are at least half a dozen clearly defined shades of color between white and dark, to be frequently met with in handling a crop of fall honey; in fact, I have had occasion to distinguish nearly a dozen different shades of so-called amber honey, in handling a single lot; and while I regard straw color, as applied to that next darker than white, as the better term, and think five shades not too many to recognize, perhaps the terms "white," "light amber," "amber," and "dark," will cover the ground.

Please add to the list of supplementary defects, an empty or partly filled cell; also that, where a section would otherwise take rank in the first grade, the presence of a pronounced defect not already specified in this list shall place it in the third grade; or if it would otherwise be placed in the second grade it shall be graded as No. 2, or fourth grade. For instance, a section whose only defect is a considerable discoloration of the entire comb surface, or a still greater soiling of half the surface, or one with, say, half or two-thirds of the surface unsealed on one side; one with one-fourth part of the comb on one side half filled; or an eighth part having empty or nearly empty cells; one with a mar covering, say, a square inch of comb surface; or a crack across the surface of the comb; a section badly discolored in the wood, or considerably soiled by propolis; or one containing honey not uniform in color. Such combs are good enough for the No. 1 grade; and where the soiling of comb surface is still greater, or even half of the entire surface is unsealed, or other defects also present that would throw them into a second grade (fancy), they should be placed in No. 2 grade.

The fancy grade should be altered so as to include as many half-filled cells as unsealed ones; also as many empty or nearly empty ones as cells of bee-bread. No. 1 should include all combs firmly fastened to two sides; also as many partly filled and empty cells as

are allowable of unsealed cells and cells of bee-bread respectively. No. 2 grade — the presence of all of the defects allowable in the No. 1 grade, in any one section, should not debar it from the No. 2 grade.

Evart, Mich., July 12.

[Mr. Byron Walker is an extensive producer and a honey-seller. When his own crop is disposed of he buys largely from others, and there is not a producer in our land, if I am correct, who comes anywhere near selling as much honey in a year as does he. He is therefore eminently fitted to speak from the standpoint of both the bee-keeper and honey-seller.

Editorially I have referred to the subject of grading. The rules that I there propose were drawn up *before* the article above came to hand; and while I believe Mr. Walker is as competent as any man in our ranks to speak on the subject of grading, I can not help feel that his rules are too complicated for the great mass of bee-keepers. I should be glad to have the commission houses express an opinion on the merits of the various rules that have been proposed—that is, which set, in their judgment, would be the most practical and feasible to apply in every-day practice.—ED.]

#### GRADING, AGAIN.

##### Only Two Grades Necessary.

BY F. GREINER.

I should consider it a mistake, if, in our rules for grading, Dr. Miller's proposition to establish more grades than two should be adopted. Two grades are fully enough—as many as dealers and producers want to bother with, I believe.

I have no particular objections to the Washington rules, and still would not want to adhere to them to the letter. My idea is, that fully half of all the comb honey produced by the up-to-date bee-keeper should go into the grade "Fancy;" the other half, or less, should find place in "No. 1," which, however, is a misnomer for that grade. Perfection is a rare thing to be found, and I am satisfied that these two grades should be much more flexible than our Washington formulators would have it. Let the new rules be so formulated as to conform to the honey as it really exists, and not to an imaginary product. Unless this is done, the producer will be obliged to modify them to fit his case. In my judgment, one or two cells of bee-bread do not condemn an otherwise perfect section of honey; nor would a dozen unsealed cells, nor a slight bulge caused by the knot-hole in a separator. This is getting down too fine.

When Mr. Hershiser demanded of us New York bee-keepers our product for the World's Exposition in the fall of 1892, I for one could send him only what little I had left of my crop—a somewhat imperfect lot. The next year he wanted to replace the old honey with new, which was all right, and he sent us his specifications as to what the honey should be.

He was so exacting in his demand that I could scarcely find six sections to answer in my whole crop, and, consequently, sent none at all. Consumers in general are, fortunately, not so hard to please, and will take in these little imperfections as a matter of course.

That the wood part of the sections be free from propolis, no matter what the kind or grade of the honey, need scarcely be specified; for no wide-awake honey-producer will crate his honey without first scraping the outside of the little boxes; that every sign of stain be also removed I hardly think will be necessary, perhaps not even desirable—at any rate, not practicable.

I also believe that three different kinds of honey are enough in our grading system; viz., white, amber, and dark. Good judgment will tell the shipper where to place the few sections of mixed honey; and if he classes them in with the lower grade he will neither harm the consumer nor himself materially.

Naples, N. Y., July 19.

### THE PURE-FOOD LAWS OF ILLINOIS.

#### Present Laws Strong Enough.

BY HERMAN F. MOORE.

*Mr. Root*.—In order that the readers of GLEANINGS may see what the Illinois law on adulteration is, I copy the same here verbatim:

CRIMINAL CODE, § 471. Be it enacted, etc., that no person shall mix, color, stain, or powder, or order or permit any other person in his or her employ to mix, color, stain, or powder any article of food with any ingredient or material, so as to render the article injurious to health, or depreciate the value thereof, with intent that the same may be sold; and no person shall sell or offer for sale any such article so mixed, colored, stained, or powdered.

#### § 473. MIXED ARTICLES TO BE MARKED.

No person shall mix, color, stain, or powder any article of food, drink, or medicine with any other ingredient or material, whether injurious to health or not, for the purpose of gain or profit, or sell or offer for sale, or order or permit any other person to sell or offer for sale any article so mixed, colored, stained, or powdered, unless the same be so manufactured, used, or sold, or offered for sale under its true and appropriate name, and notice that the same is mixed or impure is marked, printed, or stamped upon each package, roll, parcel, or vessel containing the same, so as to be and remain at all times readily visible; or unless the person purchasing the same is fully informed by the seller of the true name and ingredients (if other than such as are known by the common name thereof) of such article of food, drink, or medicine, at the time of making sale thereof or offering to sell the same.

#### § 475. PENALTIES FOR VIOLATIONS HEREOF.

Any person convicted of violating any provision of any of the foregoing sections of this act shall, for the first offense, be fined not less than \$25.00 nor more than \$200. For the second offense he shall be fined not less than \$100 nor more than \$200, or confined in the county jail not less than one month nor more than six months, or both, at the discretion of the court; and for the third and all subsequent offenses he shall be fined not less than \$500 nor more than \$2000, and imprisoned in the penitentiary not less than one year nor more than five years.

Now in regard to Ernest's "better pure-food laws" on page 493, July 1, he says, "Its first work should be to work for the passage of pure-food laws in every State in the Union where such laws are needed." Now, I am not familiar with the laws of other States, for every State is a law unto itself; but I think

here in Illinois Mr. Dadant has hit the nail on the head when he says, "Is it really necessary to have more laws than we now have to prevent the sale of glucose under the label of honey?" I will use his own words in his remarks in the above article, and say, "If such laws as are already on the statute-books were rigidly enforced" (adulteration would be almost absolutely stopped). The words in parenthesis are mine. Dadant further says, "In Ohio—because we have an energetic food commissioner," "it is very risky business to handle adulterated honey." Now, in my view the E. F. Com. above is "the whole thing." It was my good fortune, in 1887 or '88, in Tiffin, O., to listen to General Hurst, of Chillicothe, O., then the Ohio Food Commissioner. A finer, grander old man it has never been my pleasure to meet. He lectured on cold storage in keeping apples, and said that a perfectly sound winter apple could be kept five years under the most favorable conditions of cold storage as arranged especially for apples. Now, my impression of Gen. Hurst is that he made it redhot for the adulterators, and that, in my opinion, is the true and only solution of this mixing question here in Chicago. If we could have our own Dr. Miller as State Food Commissioner, at a reasonable salary of, say, \$3000 a year, so he could afford to give his whole time to it, I think the adulterators would soon all be in the State prison or some other prison. Under the law as it stands, prosecution must be started at the instance of some one interested, and is formally instituted by the State's attorney in each county. After the law as it stands has been given a thorough trial, if the results are not satisfactory the law should be amended so as to provide for the appointment of a pure-food commissioner.

In my opinion the only way to eradicate this evil of mixing is to go at it under the present law, with hammer and tongs—first the wholesale grocers and syrup-men and then the retail grocers. I am with this movement heart and soul. I suppose I have sold more honey to families in Ohio, Indiana, and Illinois than any other man in the country, beginning in 1887, and making for nearly ten years a specialty of it; and it is my deliberate opinion that, if adulteration and the suspicion of adulteration could be wiped out, the sales of honey for family use would be more than doubled.

Chicago, Ill., July 5.

[I had been informed, and I thought reliably, that the laws of Illinois on the subject of adulteration were so loose as to make it almost impossible to secure conviction; but I do not see how the text of the laws above given could be improved. I therefore acknowledge that Dadant was right and I wrong. As Mr. Moore says, it is not the want of a good law, but the want of an energetic food commissioner, such as we have here in Ohio. I make the suggestion that the General Manager of the U. S. B. K. U. learn who that functionary is, and then prod him up a little in regard to his duties. If he replies that there is no adulteration, let us set about it

immediately to secure samples in the open market, and have them analyzed. If they prove to be adulterated, bring them before the proper officials, and see that the guilty parties are brought to time. Mr. W. A. Selsler, an expert chemist, of 10 Vine St., Philadelphia, will make a qualitative analysis of suspected honey for \$1.00. I believe it would be a good idea for the U. S. B. K. U. to set Mr. Selsler at work at once; and I would therefore suggest the wisdom of the General Manager directing Mr. Moore to procure a dozen or so samples of doubtful honey, and have the same forwarded on to Mr. Selsler for analysis. My! with such a law as we have above, we are foolish if we do not avail ourselves of the opportunity to strike a blow.—ED.]

### THE UNITED STATES BEE-KEEPERS' UNION.

BY SKYLARK.

*Dr. A. B. Mason.*—I send you two dollars and fifty cents as my membership-fee (two years and a half) in the United States Bee-keepers' Union—not the little Union whose income last year was only \$38,00, but the great United States Bee-keepers' Union, just born, but rushing on to manhood with giant strides—the Union whose income this year will over-leap \$3800. The little Union is dying. Its death-knell began to toll at the Lincoln convention. Within two years it will be only a memory of the past. Why, then, give up the name of "Union"? We want no "league," no "alliance," no "association." We will stand by the name of "Union," so dear to every American heart. If our dying little sister society kicks—well, just let her kick her last. It will soon be all over. Then there will be but one union—defensive, offensive, and protective—a union that will make one grand army of united bee-keepers. Dr. A. B., here is my two dollars and fifty cents.

Room for you, stranger? Yes, if you are quick about it; for who knows how soon our coffers may be full? and then you would be barred out.

I might explain here that a coffer is a large hole in the ground, with an iron door and a big bulldog sitting on top of it. Dr. Mason has his whole garden planted to coffers and bulldogs, as witness the following dispatch:

Toledo, O., June 28.

*Dear, dear Skylark.*—In strict accordance with your suggestion I have planted my whole garden to coffers and bulldogs. They are coming on finely, as I am pushing them on the high-pressure-gardening principle, and the dollars are rolling in. A. B. M.

Yes, stranger, come in; come in *now*. Your dollar and mine, with thousands of others, will do a world of good, not only while we live to enjoy the profits thereof, but long after we lie sleeping, no matter how far apart, together in the dust. Yes, come in. We will unite with the millions who are now clamoring for pure food. We will get there, and get pure honey too.

But, one will say, "What good will stopping adulteration do me? They can not adulterate comb honey, and I produce nothing else."

Well, if I were a double-gear'd idiot that is just the way I would argue; but as I have been broken only to single harness, I am not quite such a fool. Don't you know that, if adulteration is knocked in the head, and laid out for ever, it will double the price of extracted honey? And then, presto! up goes comb honey 8 or 10 cts. per pound. Won't pay you, eh? Only a dollar a year! Count even 5 cts. per pound, each year, clear loss on your whole crop, and then say it "won't pay" you. Why, it will pay a man who has only two lives and produces but 100 pounds of honey. A. B., here is my two dollars and fifty cents.

There is not a single article of food—corn-fodder excepted—that is not adulterated—many of them with poisonous ingredients—that it is at all possible to adulterate. You may not feel that it will hurt you; you have been used to it for years; you are old and tough, and a whole plug of "Battle Axe Tobacco" would hardly kill you; but what about the little prattler that is now climbing on your knee, and lisping the name of "papa"? What effect will all these poisons have on her? Are her perfect health and security not worth a dollar a year? or do you wish to wreck that perfect model of childish beauty, just fresh from the hand of God? That is just what you are doing.

Pure food means perfect health, long life, and happiness, for there can be very little happiness without health. Adulterated and poisonous food points its bony finger to the pall, the coffin, and the grave. And you won't give a dollar a year? No! but when that little angel lies beneath the daisies—when she sleeps the sleep that knows no waking in this world, the memory of that dollar will burn the bottom out of your soul, and, like Job of old, you will mourn and lament the day you were ever born.

Dr. Mason, here is my two dollars and fifty cents.

If you can't spare a dollar a year to utterly destroy adulteration, pile up your hives and burn them. They are not worth having, or you are utterly unworthy to possess them; and you call yourself a bee-keeper! You stand there and let a highway robber pull dollars out of your pockets, and can't afford a cent to buy a brick to knock him in the head. "Oh reason! thou hast fled to brutish beasts, and man alone is mad."

Dr. Mason, here is my two dollars and fifty cents.

### BEEES EVAPORATED—A NEW MALADY.

A Reasonable Explanation of the Cause.

BY E. WHITCOMB.

On page 479 Mr. R. C. Aikin cites what at first might appear to be a new malady among bees. Several instances have occurred within my own State. This can not be attributed to paralysis or the high winds that, during the spring, sweep over most of the plains region east of the Rockies. The honey-flow coming

from the fruit-blossoms largely induces brood-rearing. The season is so far advanced that there is no longer any condensation within the hive, and, in order to rear brood, large quantities of water are necessary.

In a great portion of Colorado the streams flow directly from the snow and ice, not many miles in the mountains. The bees go forth in quest of water, go to the streams, fill themselves with cold water, are chilled, and die. The necessity for water is constantly increasing within the hive; others go forth, and share the same fate, until the whole colony has disappeared.

A paper read by us at the Lincoln convention last year effectually covers this matter; and the complaint made by Mr. Aikin is almost identical with that occurring a few years ago in an apiary near Omaha, and which was effectually cured by water within the apiary, where the water can be tempered, as best suited to the wants of the bee, by the gentle rays of the sun.

In the case near Omaha not a dead bee could be found in the apiary; but we did find them in large quantities dead around the hydrants in the immediate neighborhood. We doubt not that bee-keepers attach too little importance to what might seem to be a very small item—watering their bees within the apiary, of furnishing water of standard purity, and of a temperature best suited to the wants of the colony.

A careful study of the hive during the spring and middle brooding season has more than convinced us of the importance of watering in the apiary.

Friend, Neb., July 15.

---

### THE TWO UNIONS.

Reasons Why the U. S. B. K. U. Should be Supported; a Reply to Prof. Cook.

BY DR. A. B. MASON.

*Mr. Editor:*—Will you please tell me what's the matter with our old friend Prof. Cook? It's awful hot here to-day, and I sit by an upstairs window and look out upon our apiary (it belongs to the whole family, so I say *our*; if I didn't I don't know how soon my better half would be after me with a broom), where the busy bees seem to think this is ideal honey weather, for they are busily engaged in bringing in the nectar from the acres of white clover, and acres more of sweet clover that is just coming into bloom.

It being too hot for active work I've been looking over late numbers of bee-journals, and I feel like asking the above question; for, within a few months, less or more, I've been noticing the peculiar "antics" indulged in by some of our well-known bee-keepers who have taken Greeley's advice and gone west to grow up with the country. But something seems to be wrong. Either the country has got its growth or else the climate doesn't agree with them, or something else is the matter.

Our good friend Hambaugh seems to be all right; but just look at the Rambler. He's

been drawing on his imagination for quite a while to unravel the "Mystery of Crystal Mountain," and he hasn't got it unraveled yet, and he doesn't seem likely to for some time yet; but he's got plenty of imagination left. Will you kindly keep watch of him a little, and see that he doesn't get "luny," for there's no telling where he'll finally land if he persists in keeping in the company of such a character as Alfaretta and others of his pet friends.

I might name more of our friends who show signs of having imbibed something that has changed them from what they were when living farther east.

And our old stand-by, Prof. Cook, shows signs of having acquired a disposition to disregard the rights of others, as is shown, to me, when he says on page 449 of GLEANINGS for June 15, in speaking of Mr. Newman's construing the meaning of the vote of the National Union in January last, "If so, I am not sure but, on the plea of self-preservation, we should disregard such vote." Now, please, don't let Prof. Cook get so careless and lax in his ideas of what is right as to "disregard" the wishes of those who have paid their money into the treasury of the National Union, and who also chose him as one of the Advisory Board to carry out their wishes, and not to disregard them.

Like you, I can not agree with Prof. Cook when he says there is not room enough for two organizations. There is not only as much room now as ever for two organizations, but more. The old North American was in the field when the National Union was organized, and still there was room for it, and well have the Advisory Board and General Manager occupied the field, and protected our interests. The National Union took the field because the North American didn't occupy it all, or, rather, because a line of work needed doing that was not being done by the North American. The North American and National Union were not doing all that needed to be done, so another attempt was made to enlarge the scope of both by providing that the National Union should look after honey-adulterators and dishonest honey commission men; but a large majority of its members said *no*, and, true to his old-time faithfulness to the interests of the National Union, General Manager Newman says that voice must be heard and *obeyed*; but Prof. Cook isn't "sure" but such a voice should be "disregarded." As the result of that vote, the United States Bee-keepers' Union came into existence for the purpose of looking after interests that are more vital to bee-keepers than was that of being allowed to keep bees in cities and villages, etc. The United States Bee-keepers' Union proposes to look after the interests of its members in the same way as did the National Union, and, in addition, try to make it warn for the adulterators, and for such commission-men as attempt to defraud its members.

I am sure there is room for both the National Bee-keepers' Union and the United States Bee-keepers' Union; and I am just as sure that there is no *need* for both of them exist-

ing, and, as Prof. Cook says, "the old Union has *got* to fight living issues, or die." Why not let it die? It has done its work, and done it most faithfully and well; and right here I want to commend most truly and heartily the faithful and disinterested work of General Manager Newman, and to say that I believe him to have been and still to be most truthful and honest in all he has done; but, with many others, I believe he has made a great mistake in the course he has pursued in regard to the effort recently made to take a step forward.

But a new organization has come into existence which proposes to fight, and is now "fighting living issues," and for a "kid" it seems to be doing fairly good work.

Prof. Cook says, "I fully believe that one or the other of the present organizations will die. The division is expensive; has no excuse, and the fruits of one strong vigorous organization will be abundantly greater than of two struggling feeble ones. It will be a case of survival of the fittest." I fully believe Prof. Cook is right except in his second assertion; so, why try to bolster up the old when a vigorous, healthy "youngster" is in the field to win. We care tenderly for the old and decrepit, but we nurse and watch over and help and guide the young. As secretary I have quite a respectable bank account for the U. S. B. K. U., and I doubt not General Manager Secor has a like commodity to its credit.

As regards the second statement, "The division is expensive," I will say that I have kept a little memorandum of how many and who that have sent their dollar for membership in the U. S. B. K. U. belong to the N. B. K. U.; and, having just this moment received a list of the names of those having sent their dollar to General Manager Secor, I find that about one in fifteen belongs to the old Union. So it isn't a very expensive affair after all. The old Union has the "wherewith" with which to cheer and gladden its declining years, and it seems to me that none of the members of the new Union will wish it any thing but a peaceful old age.

Many who send their dollar to the new Union were formerly members of the old, but have dropped out because it was not keeping up with the times, and are glad to aid the new Union in its important work.

Of course, but comparatively few bee-keepers will join any organization that aims to work for their benefit. They may think, and even say, that "others will do the work, and adulteration will be done away with, and I get the benefit just the same as though I paid in my money." Every bee-keeper who sells honey, every dealer in honey, and every one who buys honey to use in manufacturing, or to consume it as a delicious, healthful, and toothsome sweet, is interested in the success of the U. S. B. K. U. and its work, and *thousands* of them *ought* to send their dollar to General Manager Secor instantanly, and have a hand in looking after their personal interest.

Before the meeting of the N. A. B. K. A. at Lincoln last October, through personal correspondence I knew where Prof. Cook stood in regard to the proposed plan of union, and he

voted against it because he "believed quite a number of the members did oppose it as unwise," and I presume a large majority of those voting against the plan did so for the same reason he did; but it always seems to me that the way to make matters move in the right direction is to look into them and decide on what is the *right* thing to do, and then do it, regardless of what others think.

Just here it occurs to me that it is a good thing to keep both Unions in a lively growing condition. I have the impression that the National Union pays but half the expense of defending a member who gets into trouble with his neighbors. If this is true, and the U. S. B. K. U. should follow the same plan, it will be a splendid thing to belong to both. A part of our apiary is located on a small city lot within a few feet of the homes of neighbors on all sides, and the rest is on a vacant lot just across an alley from the others, and families with children live on all sides; and men, women, and children get stung, but I keep the swelling down with an occasional glass or cupful of honey administered internally, at intervals, before the stinging is done.

Now, I'm a member of both Unions; and if trouble comes I expect General Managers Secor and Newman to take matters in hand and pay all the bills. Room for only one organization? Whew! Perish the thought! and all this for but a little over a dollar a year! You see the old Union has had so much honey on hand that, for several years, the Advisory Board, or, rather, the General Manager, has very kindly looked after our interests, and told us it should not cost us a cent. Don't try to kill either, Prof. Cook. Long may they both live and prosper, if such is to be the result.

Many are the good wishes that come to the new Union. Why, even its enemies are beginning to wish it well—even the editor of one of our bee-journals, who has admitted to its pages most uncomplimentary and scathing articles in regard to the new Union and some of those engaged in forwarding its interests, your humble servant included. A letter received a few days ago in regard to the coming Buffalo convention closes with this sentence: "Wishing the new Union much success, and members a good and profitable meeting, I am, etc." That shows the right spirit.

It seems to me to be hardly necessary to suggest, as Prof. Cook has done, that the members of the old Union write "to Manager Newman . . . to grapple with the question of adulteration in California." We have an organization, one of whose objects is to "grapple" with that very evil; and if Prof. Cook and others will suggest such a course to Manager Secor I've no doubt he'll look after the matter, and so not divert the money now in the treasury of the National Union from the purpose for which it was paid in, and no vote will need to be taken.

Your comments on Prof. Cook's article are very good indeed; and when you say that A. I. Root, one of the directors (Advisory Board) would be in favor of having the old Bee-keepers' Union "take up the line of work suggest-

ed" by Prof. C., you're but telling where he has stood all along; but it seems to me he ought to change that standing now. The old Union has overwhelmingly said that it did not want to spend its money in that kind of work, and I don't believe it's right and honest for the Advisory Board to disregard its wishes.

There is room for both societies. Let each attend to its special line of work, and all will be well.

I voted to have the old Union with its old and experienced staff of officers do just what the new has been organized for; but the majority said "no," and I hope the Advisory Board will be as conscientious in the matter as is General Manager Newman, and heed the Union's voice. Put me down "no" as regards the professor's plan. It would be much more difficult now to unite the two Unions, with their two sets of officers, than it would have been to unite the National Union and the North American.

I am glad Prof. Cook believes in doing the work the United States Bee-keepers' Union is doing and intends to do; and if he will turn his energies and money to building up the new Union, instead of trying to divert the course of the old into new channels, he can do much toward accomplishing what the old was not intended to undertake.

I know this article is getting to be rather lengthy; but I've tried to be brief, and I have much more I'd like to say; but I'll mention only one more matter. In the *American Bee Journal* for July 1st, Prof. Cook says he "was opposed to changing an organization . . . unless the members were pretty unanimous in the desire for such change;" and now in the last issue of GLEANINGS he is not sure but the Board should disregard such a vote. Where is Prof. C. at? Don't "disregard" the wishes of the old Union's members, professor, and we'll feel as kindly toward you as we always have.

Station B, Toledo, O., July 5, 1897.

[A. I. R. has stood right along just where your humble servant has stood. It was I who suggested to him, a member of the Advisory Board, the propriety of favoring the scheme proposed by Prof. Cook. I thought it would do no harm, and *might* in a measure help to soothe the soreness of those who can see no need of the new Union. Then, again, it seemed to me that we should place no obstacles in the way of the old Union's taking up the fight against adulteration, providing it should see fit to do so. There is a very big field along this line for both Unions, and they will not step on each other's toes even if they do fight the same enemy. However, whatever energies I have (and I am sure A. I. R. feels the same way) should be devoted toward helping the youngster that is now making such a sprightly growth. In this connection it is really painful to see how bitter Mr. Newman feels toward some of his old-time friends because they venture to offer honest criticisms on certain policies that he has seen fit to carry out. He has construed these criticisms as reflections upon his integrity and honor. No such idea, I am sure, entered the head of Mr. York or Dr. Mason, or of anybody else.—ED.]

## NOTES BY THE WAY.

BY J. T. CALVERT.

My first day's journey brought me to Indianapolis. All along the way I was most forcibly impressed with the abundance of white-clover bloom. Through all the pasture lots it spread like a white carpet. The grazing cattle and horses seemed to leave the blossoms, and eat the leaves and other grasses. After passing over one or two States, and seeing the very abundant white-clover bloom, I no longer wondered that all the dealers and manufacturers of bee-keepers' supplies were crowded to their utmost, and somewhat behind on orders. It has been years since white clover has been so abundant and so general.

At the depot to meet me was our genial friend Walter S. Pouder, of Indianapolis, with whom I spent a very pleasant half-day. He is very conveniently located at 162 Massachusetts Ave., the store reaching back to New Jersey St. Mr. Pouder has been developing the trade in honey and beeswax in Indianapolis till he has built up a very nice trade. He sells all the beeswax he receives, right at home. Quite a little for the drug trade is put up in 1-ounce cakes, 40 cakes to the box, and sold at \$1.00 a box. Honey is sold largely in square jars; and if it becomes candied before the retailer sells it, it is exchanged for that which is liquid. With the abundant crop of honey that we are sure to harvest this season, there is all the more need of developing the home market. By fair and liberal dealing, and being careful to sell only choice well-ripened honey of uniform quality, many have built up a demand in their own neighborhood, which continues from year to year, and increases with the years. What many have done many more can do.

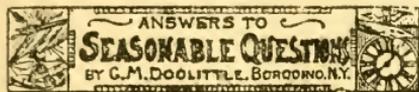

As Mr. Pouder has but one hive of bees he has to buy his supply of honey from bee-keepers who have a surplus. Much of it he takes in exchange for supplies, for he is also the principal supply-dealer of Indiana, and is prepared to supply the wants of bee-keepers throughout his State.

As I journeyed westward across the States of Ohio, Indiana, Illinois, Missouri, Kansas, and Colorado I noticed the crops more and more advanced. The wheat which was still green in Northern Ohio was golden in Indiana, and being harvested in Illinois. In Kansas the fields were already stripped; and, such extensive fields! We have been hearing for the past few years of poverty-stricken Kansas. If the most of the State compares with what we passed through from Kansas City west over the Santa Fe R. R., they should have no reason to complain, especially if wheat continues to bring the good price it has during the past year. It is no doubt having a reaction from the feverish booms of past years, but is bound to have a steady permanent growth in the years to come.

The plains of Western Kansas and Eastern Colorado are for the most part a barren waste, with very scanty vegetation. As we near the Rockies, where water is available for irriga-

tion, there is a marked change. Alfalfa is largely grown, and, as a consequence, considerable honey is harvested. As I visit this region on the return trip I will refer to it again later on in these papers.

San Francisco, Cal., July 10.

#### BEEES DESTROYED BY WORMS.

*Question.*—Going out among my bees the other morning I saw two worms at the front of one hive and three at another. I told a neighbor of this and he said I would have to look out or the worms would destroy my bees, as he lost several colonies in that way some years ago. Are there any worms which will destroy bees? If so, what are they?

*Answer.*—A good colony of bees is never destroyed by any worms which we have in these parts, and I doubt if there are in any part of the world. Such expressions as your neighbor gave voice to show the ignorance of very many regarding the enemies of the honey-bee and their lack of having studied upon the subject. However, as such statements tend to make the beginner fearful of loss of bees from the ravages of the larvæ of the wax-moth, it may not be amiss to treat the subject a little now and then in our bee-papers, explaining the workings of this larva and the only fear we need have of it. In the first place, permit me to say that no one will make the assertion that they have lost bees from moth-worms unless that one is either ignorant or careless, or both. The carelessness of such people is shown in that they do not attend to their business as they should, so they do not discover that their bees are gone till the combs are destroyed by worms; and they show their ignorance, because, if well posted in all that is going on inside the hive, at all times, they would know better. I do not propose to tell here what a wax-moth miller is, how the miller or the larvæ look, how the miller succeeds in getting her eggs in the hive, etc., for this can be found in any of the books on bees and bee-keeping. If any have not one of these books, my advice would be to get one at once, for you can not well understand much that the columns of GLEANINGS contain unless you know the first principles of bee-keeping. One who can not afford a book can not well afford to keep bees, as the loss of an ignorant person with two colonies during one year is much more than the price of a book; and yet thousands attempt to keep bees without a bee-book or a bee-paper. One thing is certain: In most localities where bees can live, if the combs are not occupied with bees, and have not been exposed to a degree of cold as low as 15 degrees above zero, when warm weather comes in the spring to stay we always find the larvæ of the wax-moth upon the combs the most abundant on those which have pollen in

them, or have had many generations of brood reared in them. When once under headway it takes but a short time to reduce the combs in a whole hive to a mass of webs. Now, the worms can not come into full possession of these combs so long as there are bees upon them, although we find here or there a worm which may have eluded the vigilance of the bees by getting in the septum of the comb, under the brood, or by being under the capping, over the heads of the immature bees. But even here they are secure for no certain length of time; for before they reach maturity they are ferreted out and cast from the hive like those our correspondent saw at the entrance of his hive. The Italian bees keep these worms out much better than either the hybrids or blacks—a handful fully protecting a whole hive of combs, the worms being kept in submission so long as a few score remain. If from any cause a colony becomes hopelessly queenless, the bees all die of old age in from fifty to sixty days from the time the last bee hatches, if in summer; and as soon as the bees are gone there is no restraint on the worms, thus giving them full sway, and in a short time the combs are ruined.

Did the worms destroy the colony? Certainly not; the colony was destroyed by the loss of the queen, spring dwindling, or whatever the cause was, and the moths came in as an effect. Thus we see to talk of worms destroying colonies of bees is fallacious. If we are not extremely careless we shall see from outside observation that something is wrong with any colony, long before the moths can take possession of the combs, even if we do no general manipulation of hives; and as soon as we see that something is wrong with any colony it is our business, as apiarists, to open the hive and find out what that wrong is, in time to save the colony. But it frequently happens that we lose a part of our bees during the winter or spring, and wish to preserve the combs till the remainder of our bees increase to occupy them, for such combs are of decided worth, even in these days of comb foundation. To keep them from being spoiled, if not entirely destroyed, by the moth-worms, requires close watching, and all should be looked over as often as once a week when warm weather comes. As soon as many worms are seen, hang the combs in a small close room, so the fumes of burning sulphur can penetrate all parts of them, and burn one pound of sulphur to every 100 cubic feet contained in the room. To burn it, get an iron kettle, put some ashes in the bottom, put in a shovel of live coals from the kitchen fire, and pour on the sulphur. Shut the door and leave for two or three days, when every thing that inhabited them will be dead, unless, perchance, some of the eggs may remain unhatched. If kept from the miller it is rarely the case that they will need looking after again; still, I have sometimes had to sulphur again in two or three weeks.

There is one thing that all can do to prevent the moth nuisance; and that is, keep every bit of comb not covered by the bees in this sulphur-room or else in the wax-extractor. To

allow combs to lie around till they become a breeding-nursery for thousands of these pests is something that many of our apiarists who are practical in other ways are guilty of. In the apiary of a man who raises honey by the ton I once saw combs by the score literally filled with moth-webs and cocoons, moths being raised to go out and curse the bee-keeping world all about. Let us not be guilty of these things.

#### HONEY SEASON NOT SATISFACTORY.

The honey season has not been satisfactory with me. Clover yielded only moderately—enough to give our bees a good start in the sections. Now basswood is out in bloom; but our bees are killing off their drones, and the honey season seems at an end. I can this year record what in all my experience I have never been able to before—not one swarm in June. Even the 4th of July passed by without one swarm coming out.

Other parties, within three or four miles of me, and others at a greater distance, I hear speak of a very fair yield, but only few swarms. A good deal of buckwheat is sown here this year as usual, and the rains are bringing it on wonderfully. This may help us out; at any rate, we are making great calculations on it.

Of course, we intend to go to Buffalo, and we hope to see a number of the noted bee-keepers of the land there. Especially do we hope to see as many of the inhabitants of Rootville as possible.

FRIEDMANN GREINER.

Naples, N. Y., July 19, 1897.

#### DRAWN COMB VS. FULL SHEETS OF FOUNDATION.

I am now taking off the Hilton supers filled with white-clover honey. I am using them on the new Dovetailed hives. It is just fun to handle them, for they come off as clean as they went on—no burr-combs on sections nor on tops of brood-frames. I don't see how Mr. Danzenbaker can do any better than this with his complicated arrangement and paraffine paper to boot. I say as I have said regarding the new self-spacing Hoffman frames, "If this is not the *best* arrangement for comb honey, it is certainly good enough." For extracting I should want four dovetailed bodies full of comb for each working colony, allowing the queen the exclusive use of the two lower ones.

Drawn combs in sections have fallen a notch in my estimation this season. I had quite a lot of them, and put them on first; but I am compelled to confess that they were not filled and sealed as promptly, nor does the finished section look nearly as well as those filled from full starters of extra-thin foundation. Now, why is this? Well, in a good steady honey-

flow, such as we have had, the bees need nothing better than foundation in order to fill and seal their sections promptly. Give them combs with cells of any depth, and they will fill them up with their unripe honey, and have to wait so long before it is ripe enough to seal that those furnished with starters are finished first and look best. I know that drawn combs are useful sometimes, and I have used a great many of them; but given such a season as this, with such a honey-flow, I do not want them at all. As far as coaxing bees up into the sections is concerned, I never had to do it yet. If you have a populous colony and a good honey-flow at hand, they will take immediate possession of the super without the aid of bait-combs.

Without those two factors there is little use of trying to work for comb honey. My experience has led me to the conclusion that drawn combs are not so all-important as some would make out.

H. LATHROP.

Browntown, Wis., July 12.

[The drawn comb referred to must not be confounded with *drawn foundation*, which is another thing. That to which Mr. L. refers was comb, as I take it, drawn out from foundation of the previous season. He does not say whether it was leveled down a *la* Taylor or not. As between drawn comb and drawn foundation, there would probably be little difference. If the latter were made 15 ft. to the lb., as we have made it, with walls only one-eighth inch deep, the comb honey would be of a finer quality so far as the comb is concerned than that built from foundation in full sheets running from 12 to 13 feet to the lb.—Ed.]

#### DISH RIGHT SIDE UP.

I find my sections are all nearly filled now, and basswood, the source from which I usually get my entire honey crop, will be blooming in four or five days, and I shall not be in readiness for it; therefore I order by express. Basswoods will be fuller of bloom than I ever saw them, and the prospects for a good honey-flow are very flattering indeed. I want to get my dish right side up.

T. K. MASSIE.

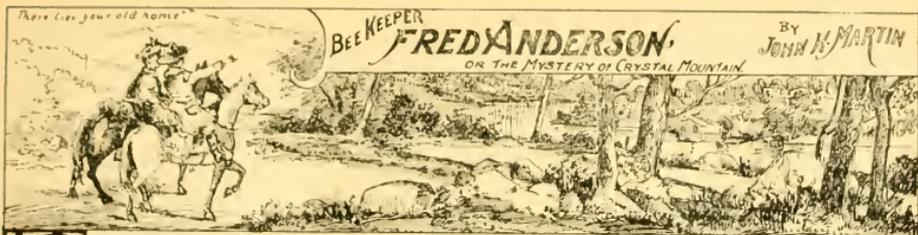

Tophet, W. Va., June 30.

#### BEEES FILLING SUPERS AS IF BY MAGIC.

The bees are almost getting ahead of me this time. I got 3000 sections and 20 lbs. of super foundation of you this spring, and had 2000 sections on hand from last season, of which 1000 were filled with drawn comb from last season, and I am just about caught up now. I never saw such an abundance of white clover as we have this year. The bees are filling supers as if by magic. About half of my bees have swarmed up to date.

Trail, O., June 24.

AMOS MILLER.

RED was greatly surprised, upon going beyond the clump of sycamores, to find the doctor with his horse and Sam's saddled and bridled as if ready for a journey.

"Why, doctor," exclaimed Fred, as he hastened forward, "what does this mean? Are we to break camp now and get to Prof. Buell's in the early morning?"

"Oh! no, Fred. Sam and I thought we would take a little journey on our own account; but first I wish to talk with you;" and the doctor leaned against a sycamore, folding his arms across his breast as though to hold together all of his powers. "I have been thinking much of late of my position and condition in the world's affairs. I feel that, at my age, and with my habits of life, it is impossible for me to conform to the usages of the ordinary so-called civilized community; and, furthermore, I have searched for years for a daughter, and fondly hoped that, when found, I should also find a daughter's love; but, Fred, having found that daughter, I do not find a daughter's love; and I never—no, never—shall. She loves her supposed parents, and, in fact, they are parents to her in all except the matter of birth. To step in now and reveal myself as her father would be a cruel blow to her happiness. Do you see," said the doctor, with greater earnestness, "how her eyes brighten and her face glows at the thought of meeting her parents? how she thinks our pace slow? and, had she wings, how she would fly to the home that shelters those she loves? And I, should she know of my relation to her, at the best I should merely have respect—an uncle's or a cousin's love. No, Fred," said the doctor, in a decided tone, "I can endure no second-rate love. The fates have decreed that this should be so, and now I should feel especial dishonor to stand between Alfaretta and those whom she holds dear. I can cherish the memory of having found her, and of being instrumental in restoring her to mental health. And now, Fred, you must know that my plan is to go far from this place, where I can surround myself again with animal life, and live in quietness. Convey to Mr. and Mrs. Buell what I have told you, but never reveal to Alfaretta the relationship that exists between us. Let me remain to her as Uncle Ralph. And now, Fred Anderson, farewell."

While the doctor was talking, Fred's emotions were first surprise, then grief; and when the doctor mounted his horse he could scarcely control himself. His words of appeal fell upon deaf ears; and finally, as the doctor

moved off, Fred's words of farewell were broken with sobs of genuine grief, for he had learned to love this unselfish man. Sam Johnson silently gave a parting hand-shake, and Fred was left alone.

Slowly returning to the camp-fire he stirred the dying embers to a flame, and sat for a long time musing upon the strange events through which he had passed during the past two years. Sleep did not come to him any more that night. The coyote set up his indescribable yelp not far away, and an owl screeched and screeched in the sycamore-tree, but Fred heard it not; he was living in another realm. He arose, finally, and said to himself, as he looked toward the little tent, "If I do not soon win this woman's love I too will follow Dr. Hayden."

The little tent soon showed signs of life, and at an early hour Alfaretta emerged from it. She had been informed that she was but half a day's journey from her home, and her excitement increased, and she was impatient to continue the journey.

Her first comment, upon emerging from the tent, was, "Why, Fred Anderson, how solemn you appear. You look as though you had lost your best friend." The next moment she said, as she surveyed the camp, "Where is Dr. Hayden?"

"If the expression of my face is so sad that even your presence can not enliven it," said Fred, "then I will say that we have both lost an excellent friend;" and he related the episode of the night.

Alfaretta's surprise was great, and her chagrin greater; "for," said she, "I had anticipated so many pleasant things for him; how full of joy, and how grateful, my parents would have been! and I would always have loved him as my dear Uncle Ralph. But, what a mysterious man! and, Fred, I dreamed last night that he looked into my tent and gazed a long time upon my face, and then floated away up like a cloud."

"I reckon yer dream was all true, 'cept the cloud," said Gimp; "fur I seed the doctor a looking inter the tent."

There was not much relish for food that morning, except by Gimp. Camp was broken, the donkeys packed; and as they proceeded on their way Gimp finished his breakfast from remnants he had tucked into his pockets. Trouble was not allowed to interfere with his gastronomic affairs.

Alfaretta—how radiantly beautiful she appeared! The flush of early morning exercise upon her cheeks, her eyes sparkling with joyous anticipation, erect and alert, to Fred's

eyes she was the very embodiment of health and loveliness; and he, with many conflicting emotions passing through his mind, rode for many miles with but little conversation between them.

This silence might have continued through the remaining portion of the journey; but after crossing the Sacramento River the road led diagonally up a steep bluff. Alfaretta's pony was upon the outer edge of the grade, and at one point the embankment was supported far below by log-work. The earthquake had evidently loosened the logs, and the tread of the pony caused the embankment to slide down a few feet. It was not much of an accident—rather more startling than injurious. The pony made a desperate struggle to regain the roadway. Fred, whose horse was close in on the grade, and not caught in the slide, leaped from his horse and was by Alfaretta's side instantly, and aided the pony to gain the roadway.

"My!" said Alfaretta, trembling; "how it frightened me! but I didn't shriek, did I, Fred?"

"Oh, no!" said Fred; "you are too brave a girl for that."

A little further along, after regaining her composure, she said: "How good of you, Mr. Anderson, to again guide me out of peril!"

Fred felt a little chill at the words "Mr. Anderson;" but having a resolve in mind he nerved himself for the effort of his life, and said, in a low, earnest tone, "Alfaretta, would that I could be your guide through all of your life. You are going to your home with joy; let me have the great pleasure of going with you, hand in hand, for weal or for woe. If I have been your guide in dangerous places, you now by one little act can requite it a thousand fold. I close my eyes and reach out my hand, tempting fate."

Fred's horse was near Alfaretta's, and for a moment he felt suspended between heaven and earth; every beat of the heart seemed an age. Would she clasp his hand? The thought of her refusal caused him in imagination to sink down to unutterable depths of despair. But, oh the rapture! Could he believe it? her hand sought his, and now the thrill of joy lifted him as far above the earth as, a moment before, he was below it. Claspings Alfaretta's hand more closely, he opening his eyes, and looking upward, said, "Oh sunshine! how glorious! how grand the great dome of heaven! how beautiful the earth, radiant with floral gems! how sweetly sing the birds! and the very winds breathe music through the trees; but far above all these the love of woman rules and beautifies the world. Without that love it would be a barren waste indeed;" and he raised the hand to his lips and kissed it.

"Well, I declare, Fred," said Alfaretta, "you are getting decidedly sentimental. I really believe we are on earth yet, though."

"That may be," replied Fred, "but it has suddenly become a new earth to me."

Their conversation was here interrupted by the arrival of Gimp, whose horse came up on a lope. He had been interviewing the operator of the ferryboat about the fishing; and

before he was near them he shouted, "They say the fishing is purty good along this yer river now."

"That may be," said Fred, with a smile; and, turning to Alfaretta, he said, "Then you remember nothing about pulling me from the river with the fish-pole, and calling me Mr. Pickerel?"

"Nothing whatever," replied Alfaretta; "it is all a blank to me, as well as any remembrance of the lovely home you say we have on this river."

"Yes, Alfaretta, it is a lovely home; and when we reach yonder bend you shall see it. Over yonder," and Fred pointed across the river, "is the Ghering ranch; and that white-appearing rock out in the tules is all that remains of the bluff upon which I had my neat apiary and beautiful honey. Why, as I look across I feel almost like shouting for Matt Hogan."

"And to think what ill luck you have had with bees—this apiary swarms away, and those hundreds of valuable swarms overwhelmed in the valley! Fred, I think you should give up all idea of keeping bees."

"Oh, no!" replied Fred; "all of these discouragements have given me training for better work in the future. I believe I can now fit up the most scientific practical apiary in the country; at any rate, I am anxious to try it. But here we are at the river bend. Now for your first glimpse of home through sane eyes; but what is the matter, Alfaretta? You look pale; please be a brave girl now, and control yourself."

"I will try, Fred; but you scarcely realize that it is over five years since I saw my people to sanely remember them, and all of these years of anxiety and sorrow must have wrought changes. I shall not see the same parents I saw five years ago; and are they at home? are they alive, Fred? are they living here? Oh the conflict of these thoughts!"

"Courage, dear; we shall soon know all; see, there is smoke from the chimney. Somebody is waiting for you."

*J. U., Neb.*—Perhaps you have not seen a sample of the drawn foundation. We have made some that runs 15 feet to the pound, with cells  $\frac{1}{8}$  inch deep. When the cells are  $\frac{1}{4}$  inch deep it runs about 11 feet to the pound. Even this is nearly as light as thin foundation, but heavier than extra thin. But our thinnest drawn foundation is lighter than any foundation that has ever been made having any wall. The drawn foundation running 15 feet to the pound is very much lighter than the extra-thin foundation, which is only 13 feet to the pound. Perhaps you have been relying on statements made by those who oppose the new drawn foundation. If you have, we would suggest that you send and get some samples from our latest dies. If the new drawn foundation should come into general use, if we made it as light as 15 feet to the pound it would take much less wax than foundation does at present.

THE officers of the United States Bee-keepers' Union have gotten out a very neat and elaborate program for the Buffalo convention, to take place Aug. 24-26. This program contains, besides, nine special songs, the music and words of which were gotten up by bee-keepers. These programs are to be sent free to all members of the Union; to all others a nominal price of 5 cents will be charged. Address the secretary, Dr. A. B. Mason, Station B, Toledo. The music is simply delightful. Send for a program, and try the music in your home.

#### FREE HONEY-LEAFLETS.

IN order to help bee-keepers sell their big crop of honey we have decided to furnish, during the month of August, honey-leaflets free, in quantities not to exceed 500 to any one person asking for them. But to be eligible to this offer the person must be a subscriber or have ordered goods of us at some time during the season. He must also pay express or postage. If the leaflets go with other goods, there will be no charge to pay. I am so firmly convinced that they will do good work where distributed among grocers and consumers that we are constrained to make this offer. Let the orders come in—the more the merrier. Postage on 500 leaflets will be 50c; on 100, 15c.

#### THE ADVANTAGE OF BIG COLONIES.

I HAVE said a good deal regarding the advantage of large colonies being non-swarmers, and the kind that produce honey. Experience this season, as well as last, has pounded the fact into my head more firmly than ever before. The Dadants have long been exponents of big hives and big colonies; and while I believe they are exactly right in urging the importance of having powerful stocks of *bees*, I am not yet prepared to believe that a large hive all in one brood-nest is essential. During the past season we have secured largely the same result as do the Dadants, with our two-story eight-framers; namely, no swarms and 100 lbs. of extracted honey on the average, per colony, and 50 lbs. of comb honey. The single-story eight-framers swarmed, and in some cases gave us 25 lbs. Hard facts and figures like these are worth a bushel of theories. In addition to the two-story colonies we have a few three-story and one four-story; the last named holds two *big* swarms. If they had been at the out-yard instead of at the home yard, that is greatly overstocked, we should have secured some results.

#### THE DADANTS ON BEES HANGING OUT DURING THE HONEY-FLOW.

WE are at present enjoying a visit at the Home of the Honey-bees from Mr. Louis Dadant, son of C. P. Dadant. That is to say, he is a son of the "son" of Charles Dadant &

Son. He reports that they have had an excellent foundation trade this season, as well as a good honey-flow. One of the first questions I asked young Dadant was whether they had been having any swarms.

"Not a swarm this season," was the reply, although they had 80 strong colonies at the home yard.

"Do your bees ever hang out?"

"Yes, sometimes, if we do not keep ahead of them and give them sufficient room. But when they cluster out in front we raise the hives off the bottoms, thus giving them ample ventilation. This starts the bees to work."

This is in line with what I said in our last issue in regard to bees hanging out. It will be remembered that the Dadants have few or no swarms, and this fact speaks volumes for the advantage of having large colonies. But I shall have something more to say on this question, in another column.

#### MORE FISHBONE IN NATURAL DRONE COMB THAN IN COMB BUILT FROM FOUNDATION.

WHEN the question of the new drawn foundation came up, some opposed its introduction, on the ground that it would make more fishbone in comb honey, and even went so far as to condemn the practice of using full sheets of foundation in place of narrow starters, as they averred that the former made too much "fishbone." I never had a question but that full sheets of foundation would result in a heavier midrib than ordinary natural built comb; but if our experiments and observations, as reported in our last issue, mean any thing, it would appear that there is actually *less* of the objectionable article in comb honey from the use of full sheets than where only narrow starters are used. If the bees would build *worker* comb in place of drone comb, after extending beyond the narrow starter, then the results might be different. It would look as if the talk, to the effect that the comb honey of our fathers (as a general rule drone comb) was better than the comb honey of the present day, were based more on theory than on experience or observation.

#### EXTENT OF THE CLOVER HONEY-FLOW; A BIG YEAR FOR SUPPLY-DEALERS.

MR. W. A. SELSER, the honey-man, of No. 10 Vine St., Philadelphia, called on us recently. He had been out west buying up honey; and he reports that the honey season, while fair in Minnesota, Iowa, and Wisconsin, was not as heavy as in other States in the North. Basswood had been to a great extent a failure, while clover did only fairly. Mr. M. G. Chase, of Whittlesey, said last week he had a sort of feeling that the honey season would not pan out as well over the country as we had at first expected. He urged that, if the crop was not to be a big one, the report that it would be would demoralize commission men so that they would not dare to make prices; and so if they quoted at all they would quote low. This, he thought, set the pace for the rest of us. There may be something in this.

On the other hand, if we can judge the hon-

ey season by the flood of orders that has come in, the flow has been the greatest in extent and duration that we have ever known. Here we are up to this date, July 24, running night and day, machinery and engines strained to their utmost, and we expect to run nights another week. Usually our rush of business is all over by the 1st of July. We began running night and day the last week in April, and during this time we have employed the largest number of hands we have ever had in our experience. As nearly as we can learn, our brother-manufacturers have also had a heavy run of business, all of which goes to show that the season of 1897 will go down into the records as being one of the best that bee-keepers have ever known. Prospects are exceedingly bright for another season.

#### OVERSTOCKING AT THE HOME OF THE HONEY-BEES.

We have 300 colonies and queen-rearing nuclei at the home yard, and 40 full stocks at the out-yard. It was evident from the very first, as I stated, that the bees away from home were doing altogether the better work. Only a few comb-honey supers were filled and capped over at the home yard, while at the out-yard every one of the colonies was in the supers for all they were worth. The out-bees would fill a super in about a quarter of the time the home bees did, providing they did any thing at all. Another fact is, that the home yard is at the present time just barely holding its own. Indeed, they are ready for fighting and robbing. The out-bees are still gathering honey and capping sections, at least they were on the 23d.

All these results would naturally be expected; but it goes to show that the number of 300 colonies and nuclei is overstocking our home yard with a vengeance. It is probable that the out-yard would take at least another 40 colonies, without very much detriment to those already there.

#### AN IDEAL LOCATION FOR BEES.

For myself, at least, I have decided that the ideal place for an apiary is in an orchard, where there are low-spreading trees. If the queens' wings are clipped, there will be comparatively little climbing after swarms. Some prefer shade-boards; but after having tried both, for the comfort of the apiarist and that of the bees I decidedly prefer the shade of low-spreading trees. Grapevines do tolerably well, but they do not protect the apiarist; and at this time of the year, when the shade is most needed, they are sending out shoots and branches that interfere with the handling of the hive; and grapevines do require an excessive amount of trimming just at the time bees need the most attention. The colonies at our out-yard are placed in groups of three on the north side of the low-spreading basswoods. It is a great comfort as well as a pleasure to work among these bees compared to what it is in the home yard with the grapevines. Vernon Burt has his apiary in an apple-orchard, and the grass is neatly kept down by sheep that are allowed to run among the hives at will.

The lawn-mower does not begin to compare with them.

#### L. L. LANGSTROTH.

I AM informed that as yet no tombstone has been placed to indicate the spot where the remains of our old friend and benefactor rest. Now, while I would not recommend extravagance in this matter I certainly do think the bee-keepers, not only of America, but of the whole world, would gladly give something to have a proper stone furnished. I am told that \$50 has already been subscribed; but to my mind, all things considered, this is hardly sufficient. If those who have enjoyed and been profited by father Langstroth's writings should contribute only a *dime apiece*, it would be enough and *more than enough*; and I am sure bee-keepers would willingly do this. In fact, if I am correct most of them would feel it a privilege. The only difficulty is to get the matter started, and to let people know about it. I myself will gladly give \$10.00; and if enough is not raised to pay for a fitting monument, I will do more. Send the money to us and we will see that it is properly credited; but send as much more than a dime as you can afford.

And it occurs to me just now that some of our able men, friends of our benefactor, should meet together and suggest a suitable inscription. I have not consulted any one in regard to the matter, but I should like to have Dr. Miller and Manager Secor, and anybody else whom they might choose, get something appropriate for the tombstone. The whole wide world knows more or less of Langstroth; and people who visit the cemetery at Dayton, Ohio, will look up the place and will read with interest the inscription. When I was down east it gave me a rare thrill to be shown the burying-place of Noah Webster, the father of our old "elementary spelling-book." I can not remember just how expensive a stone it was; but I was not only delighted to see it, but to tell the friends after I got home that I stood by the tomb of this, that, and the other great men whose memories we love and revere. Now, then, when you are writing us tell us what your mite toward the fund shall be; and if you can not all see the stone, and read the inscription, we will try to give you a good picture of it in GLEANINGS.—A. I. R.

#### GETTING BEES STARTED INTO SECTIONS; THE ADVANTAGE OF POWERFUL COLONIES.

WE have had quite a number of inquiries as to how to get bees to go into sections. Some have said that their hives were full of honey, but the bees would refuse to go to work above. The main trouble in most cases is that the colonies are probably not strong enough. If they can only comfortably fill the brood-nest they may not go into the supers, even if honey is coming in freely. Hives should be fairly *boiling over* with bees. With this condition, and a fair honey-flow, there ought to be no trouble in getting work started in the supers. But it is always advisable to put in a partly finished section or sections from last season, or, better yet, from another colony in the same

apiary, that is working in the sections. These we call "bait-combs," and every wise apiarist will put one or two of them in the center of his supers along with sections containing *full sheets* of foundation. The average bee-keeper can not afford to use narrow starters.

A great deal of stress has been laid on the importance of putting in bait-combs to start the bees up; but a greater stress should be laid on the importance of having big rousing colonies. The hives should be "shoost cramm't chann full" of bees; then when supers are put on, the bees will go into them. When *once* here they won't loaf long if honey is coming.

#### SHEEP TO KEEP DOWN GRASS IN THE APIARY.

A few days ago Louis Dadant and I called at Vernon Burt's. He was away at the time, but we strolled into the yard nevertheless. Quite a flock of sheep were busily nibbling around among the hives. I had supposed that Mr. Burt allowed them access to his apiary only at night; but latterly, at least, it would seem that he lets them go among the hives day and night as much as they please. I saw some sheep nibbling grass close to an entrance. Did the bees make any fuss about it? Well, yes, but the creature did not seem to mind it. One old woolly chap I noticed was walking across the apiary at a little quicker pace, with his head quite low. By looking carefully I saw that a lot of bees were after him. He plunged his head into a clump of twigs, and wiggled his stump of a tail in a show of self-defense. He shortly drew his head out, and went to nibbling grass around the hives as though nothing had happened. Another sheep seemed to be stung in the face, but paid very little attention to it. Just imagine a cow or a horse or a donkey, with bees after them, among a lot of hives! No cartoonist has or ever could fitly represent the "scene." Thick heavy wool protects so that, I believe, they are rarely stung; and even when they are, as I said, they pay no particular attention to it.

I don't believe there is any thing equal to our woolly friends to keep down grass and weeds in an apiary. It takes lots of time and hard work to do an equally good job with the lawnmower. At our home yard there is an open roadway over which considerable basswood lumber is hauled, and more or less general teaming is done. Were it not for this fact I should be in favor of having a flock of sheep to keep the grass down in our apiary.

#### GLEANINGS PRINTED ON NEW TYPE AND ON A NEW PRESS; SOMETHING ABOUT THE PRINTING FACILITIES AT THE HOME OF THE HONEY-BEES.

Our readers will notice that this issue is printed on a new dress of type, the old having become so much worn as to make a change necessary. It is also printed on a brand-new Campbell Century four-roller book and job press that has a guaranteed capacity of 2200 impressions per hour, or a normal rate, including stops, of about 18,000 printed sheets in a

day of 10 hours, each sheet having 16 pages of GLEANINGS matter on a side. This machine cost us \$2500 in cold cash.

Our printing department has been so crowded during the past year that we had to have something better; as it was, the old press ran night and day from about the first of January to the middle of May last. We have realized for some time also that it has taken too long for us to run off an edition of GLEANINGS. With the old press it took from four to five days; but we expect with the new machine, as soon as our boys learn to feed it to its full capacity, to make the run in something like a day and a half, or possibly less.

Besides the printing of our journal we have from 150,000 to 200,000 catalogs to print, of our own, every season; for we believe heartily in the principle that we must let the world know that we have something to sell. Then there is our A B C book and several rural publications. Besides this there is some outside printing. The consequence is, we have found our capacity heretofore to be so limited that we found it necessary for us to buy the very best and fastest printing-press that could be found in the market; and after a good deal of investigation it proved to be the new Campbell Century—a press that is now almost working a revolution in printing-presses. I believe there is no one other *book* and *job* press of its class that can equal it in speed day after day without "playing out."

Good by, old press! good-by, old type! and welcome new type and new Century and progress! While GLEANINGS does not claim to be the *best* bee-journal in the world, it has a right to claim that it "keeps up with the procession," both in subject-matter and in letterpress work. Besides this we shall continue to bestow, as in the past, extraordinary care upon our proofs.

#### THE NEED OF STANDARD GRADING-RULES; A SHARP TRICK OF THE TRADE.

It begins to look as if it were impossible to find a set of rules for grading that will suit even the experts in bee-keeping. Some even go so far as to think it better to have no rules, and let each one grade according to his own notion. The obvious disadvantage of this is that one lot of honey can not be compared with another. A's "Fancy" would be B's "No. 1," and C's "Extra Fancy" might be D's "Fancy." We must somehow strive to arrive at uniformity. Without grading-rules a commission house can *sell* B's honey as "Fancy," and make him returns for the honey at No. 1 grading. By this way they can actually steal the difference between the price of No. 1 and Fancy. Yes, even with a standard set of grading-rules they could carry on this sort of stealing, but it is not nearly as easy to do so; for with standard rules each party would know what he is talking about; but without rules the bee-keeper is at the entire mercy of the commission house. I regret to say it, but I fear that the practice of selling at one grade and making returns to the bee-keeper at a lower grade is more common than it ought to be because it is so easily done and

so difficult of detection. A good set of *standard* grading-rules would be a great bar to the practice.

#### GRADING-RULES FOR HONEY.

Up till within a few days preceding the 15th of July, not a single postal or letter had come to hand indorsing or criticising the grading-rules that were proposed by Walker, Miller, and others in the July 1st issue. Before Mr. Walker's article was received, and which is published in this number, I tried my hand at grading—that is, I tried to bring the matter down to a focus by bringing the thoughts of others into one system of grading. In the first place I took the Washington grading as a background, and then incorporated mainly the suggestions of Dr. Miller, in our July 1st number, who had previously considered those put forth by Messrs. Thompson, Walker, and others. Here are the rules that I “doctored:”

**FANCY.**—All sections to be well filled, combs straight, and firmly attached to all four sides, the comb unsoiled by travel-stain, or otherwise; all the cells sealed except the row of cells next to the wood; the outside surface of the wood well scraped of propolis.

**A No. 1.**—All sections well filled, but combs uneven or crooked; one-eighth part of comb surface soiled or unsealed, or the entire surface slightly soiled.

**No. 1.**—All sections well filled, but combs uneven or crooked; one-eighth part of comb surface soiled or unsealed, or the entire surface slightly soiled.

**No. 2.**—Three-fourths of the total surface must be filled and sealed.

**No. 3.**—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be “fancy white,” “No. 1 dark,” etc.

The “Fancy” and “A No. 1” correspond exactly with Dr. Miller's “Fancy” and No. 1 on page 483, July 1st issue. I have changed the designation of the second grading, putting it “A No. 1.” No. 1 is identically the same as A No. 1, you will notice, with the exception that no mention is made of the scraping of the sections. The greater part of honey that is put out is in sections not scraped; and it follows that the greater part of all honey sold will be in sections soiled or unscraped, and should be designated as “No. 1.” I know Dr. Miller believes that most honey put out is scraped; but if he will go over the markets as I do, and buy honey as our firm has done, he will note that very little of it has been near the scraping-knife.

Mr. Walker and a number of others pointed out that more than two grades are necessary to include the bulk of marketable comb honey. It will be noted that I have already added one extra grade to take in the bulk of comb honey not scraped; namely, No. 1. I now add two more—the No. 2 and No. 3 that Dr. Miller proposed some years ago, and which we reproduced on page 482, July 1st issue. Such honey should not be put on the market; but as it is, nevertheless, it must be designated in some way or other.

I have carefully looked over Mr. Walker's revised grading-rules in this issue, and the only criticism I have to offer is that they are too wordy, and there are too many little conditions and points that one would have to bear in mind to grade by. The rules must be very

simple to be operative. Really, I do not know which would be the better rules to abide by—those above given, those proposed by Mr. Walker in this issue, page 551, or some other.

The editor of the *Review* believes that the Washington rules—those we have been using right along during the two past years—were all right—good enough for anybody—that we mustn't expect to suit every one.

#### ERRATIC SWARMING FOR 1897; THE SPRAY-PUMP A NECESSITY.

JUDGING from the letters that have come in, and from our own experience, swarming this year seemed to be a little more erratic than usual. In our own vicinity, for instance, the bees have seemed determined to go off without first alighting; and it has been only by the most vigorous use of the spray-pump that we have been able to hold them. One swarm actually left us. It seems they flew high into the air, went over the factory buildings, clear out of the reach of spray-pumps and every thing else, and didn't even say, “By your leave.” One other swarm I was just able to reach with the spray. They were fast making off when I wet down the wings of the leaders, changed their course, and finally, by vigorous dousing, induced them to alight. Heretofore we have been in no great hurry to take care of swarms when they came out, because we knew they would alight before going away.

I noted in Straws for July 1st, that Dr. Miller asks why we do not clip, and save all this nonsense. As we make quite a business of selling queens, we find that our customers do not all want their queens' wings clipped. When a man sends off a distance to get a queen he likes to show his beauty to his friends, and, of course, wants her to look perfect—not one-sided. We are obliged, therefore, to put up with the nonsense.

#### A CHANGE OF MIND.

The foregoing was prepared for our last issue, but it was crowded out at the last. I just want to say that I have changed my mind. The care of swarms devolves upon your humble servant, Sundays and at the noon hour. I may be mistaken, but it *seems* as if those pesky bees selected their times to swarm when I am on the watch. So far as I am concerned, I have about concluded that, in the future, our customers will have to take “one-sided” queens or go somewhere else. I have chased and squirted, climbed trees, and puffed and fumed, till I am tired. We have already begun the process of clipping our queens' wings; and if our customers do not like it—well, they can just go elsewhere.

Our tested and high-priced queens are, as a rule, in big colonies that can produce honey. I used to feel that a colony could spare its queen in the height of the honey-flow, and then there would be no danger of swarming; but, as I have shown in last issue, p. 531, a queenless colony sulks too much. I am wondering whether a queen-rearing apiary, a comb-honey apiary, and an extracted-honey apiary can be combined all together all at once. The echo in my own mind says, “Nit.”

## OUR HOMES.

Oh full of all subtilty and all mischief, thou child of the devil, thou enemy of all righteousness, wilt thou not cease to pervert the right ways of the Lord?—ACTS 13:10.

Our readers may remember that, during the year 1895, I at different times mentioned the electrical fraud or humbug called Oxydonor, in connection with my repeated warnings in regard to the humbug toy called Electropoise. The matter would probably have never been referred to again were it not for something I saw in the Patent Office *Official Gazette* for July 6, 1897. On page 185 we are told that, on the 15th of June, 1897, a patent was granted to Hercules Sanche. This Sanche applied for a patent on his swindling Oxydonor as early as 1887. His application was promptly rejected, on the ground that it was not an electrical apparatus—there is no electricity about it; and also that his claim, that it extracted oxygen from the air for the benefit of the patient, was ridiculous. He then admitted there was no electricity, but claimed that some other force circulated through the wire hitched to the patient's ankle. He also dropped the oxygen part of it; but it was again rejected. Permit me to make an extract from the *Official Gazette*:

On January 31, 1888, these claims were rejected by the Primary Examiner for the reason that the apparatus must, if operative at all, be subject to the laws of electricity, or of some other force; it is not at all satisfactory to present it as an electrical apparatus, and at the same time to say that it is not subject to ordinary electrical laws, as has been practically done. It is not admitted that the body is a magnet, or subject to the laws of magnetism; and if it were, the apparatus described would have no influence upon it.

The numerous affidavits which have been filed relate to the treatment described in another application, and have no bearing on the present case; and in any event, affidavits of the patients would not demonstrate the operativeness of the apparatus as an electrical device.

But year after year it seems he has kept on. Let me extract again from the words of the *Official Gazette*:

After a careful re-examination and consideration of the arguments and evidence presented, my conclusion is unchanged; that is, that the invention is not "sufficiently useful and important" to warrant the grant of a patent. (Section 4902 of the Revised Statutes.)

The novelty of the apparatus is admitted, and the affidavits and testimonials presented, together with the unsolicited reports that have come to me, leave no doubt in my mind that the use of the apparatus has in some way benefited some of the persons who have tried it. I am still of the opinion, however, that the favorable results obtained were due largely, if not wholly, to the imagination of the patient. It is a common practice among physicians to administer bread pills in certain cases; and the wearing of an iron ring upon the finger, or the carrying of a potato in the pocket is regarded by hundreds of people as a certain cure for rheumatism. Scores of similar remedies could be referred to, all of which depend for their efficacy upon the power of the imagination. The present application, in my opinion, is of this description. I could not conscientiously sign a patent for the apparatus in question.

The former decision is adhered to.

Finally, however, in June, 1897, this man Sanche, by some hook or crook, has gotten some sort of patent. The reasons for revoking the former decisions and granting the patent are given below:

"If some scientist will devise some way or means of working on the imagination so as to cure physical dis-

ease, he will be a public benefactor, and this Office will be prompt to issue a patent to protect him in the enjoyment of his invention or discovery, if it has the element of novelty. For we may be thus able to dispense, in part at least, with the nauseating decoctions that are now presented to our lips whenever we are ailing."

It is thought that this claimant is justly entitled to a patent under the law, and the decisions heretofore rendered denying him a patent are set aside.

Now, friends, you have the history of this disgraceful affair, or at least a glimpse of it, before you. It is not only a disgrace to the man Sanche, for he is too hardened a sinner to hesitate at any thing to secure his purpose; but just consider the fact that our Patent Office should grant a patent, and permit the patentee to go out and humbug sick people, because they would be better humbugged in this way than to be dosed with "nauseating decoctions"!—taking it for granted, it would seem, that neither the one nor the other has any effect on the patient. We might laugh at the matter, and call it a joke; but this Dr. (!) Sanche calls himself not only a physician and a scientist, but a *Christian*. His hypocritical swindle is worked mainly through our religious periodicals. A while ago he secured the confidence of the women of the W. C. T. U., and persuaded them that he was a benefactor of mankind, and so got his fraudulent advertisements into their publications. He made it appear that he was a companion of Woolley and Moody. Our readers may remember that I exposed the latter scheme, and got a letter from Mr. Moody himself, saying that he knew nothing of the man or scheme, and never gave permission for his name to be used in any way whatever.

In God's holy word we have several accounts of the way in which the prophets of old pronounced sentence on those who appropriated "the livery of the Lord to serve the Devil in." Ananias was struck down dead; Gehazi, the servant of Elisha, when he undertook to make a little money because of being a servant of one of God's prophets, was smitten with leprosy; but in this nineteenth century, with all of our progress in science and art, and especially our discoveries in electrical science, such men as Sanche go about and ply their trade almost unrebuked. Religious papers accept their advertisements; and when anybody remonstrates, they reply that it is not their business to inquire into scientific merits of the thing; and even our Patent Office grants a patent when sufficient impertunity is brought to bear, for no other excuse than that many of the drugstore medicines have no more sense or science to back them up than "the wearing of an iron ring on the finger, or the carrying of a potato in the pocket," . . . . "as a certain cure for rheumatism."

Our Patent Office examiners are sharp enough and bright enough. Sanche's twaddle about oxygen and electricity, and some other force running along a single wire, was not listened to a single moment. He was ruled out again and again. If you want the history of the whole thing, send for the *Official Gazette* of July 6.

In our previous issue I spoke of letting rats and mice encroach upon us because of our

half-heartedness; but how about letting these thievish rascals in human form prey upon us?

A young lady, who is almost our next-door neighbor, heard of Oxydonor, and was actually considering investing \$25 of their hard earnings. Are the editors of our religious papers excusable for receiving advertisements of things they *know* and *admit* to be frauds and humbugs? Dr. O. W. Holmes said, some years ago, "Quackery hobbles along on two crutches. The one is the superstition of women, and the other is the indorsements of clergymen." Instead of clergymen he should say the editors of religious papers, to better fit the present time. You know, friends, how I have labored in this matter; but if I should take this *Official Gazette*, and read this whole thing to the editors of some of our religious papers, they would coolly inform me (in substance) that it was no business of theirs so long as they *got pay* for the advertisement! Let me digress a little.

A few days ago my sister, Mrs. E. J. Gray, a prominent worker and officer in the W. C. T. U., while attending a temperance meeting at Lakeside changed cars at Elyria and went in to purchase a ticket. A dull, stupid, country-looking chap stood in her way while she was purchasing her ticket. When she attempted to go out of the door this same chap stood in the doorway, evidently not having sense enough to go either out or in. She then noticed stupid-looking, awkward country chap No. 2, and they were around pretty near each other. When she attempted to board the train, these two ever-present "greenies" were in the way again, and she began to lose patience at their stupidity. The leader did not really seem to know enough to get out of the way; but she finally managed to get past them, but in doing so they gave her quite a push. She passed on, feeling vexed to think that anybody could be so dull as to be a continual stumblingblock in the way of busy people. Pretty soon she noticed her handkerchief half way out of her pocket, and then she found her pocketbook was missing. Then the whole thing revealed itself all of a sudden. This fellow was a pickpocket, and No. 2 was his "pal." She remembered the latter standing near, and almost remembered something passing between them when she jostled against No. 1. He stood by the ticket-office window to see where she kept her pocketbook; then he tried to get it while she pushed past him when going out of the door; but when he got in her way the third time, as she was getting on the train, he succeeded, and passed the purse to his pal, so that, even if she had had him arrested, she could do nothing. The ticket-agent informed her afterward that as many as three pocketbooks were found on the sidewalk that morning. These fellows quickly emptied out the money, dropped the pocketbook so to escape identification, and then stood around watching for more "game."

Permit me to say, before dropping the subject of pickpockets, that we should get rid of this pest of society and civilization just exactly as we get rid of rats and mice; and, furthermore, it is a disgrace in the locality to

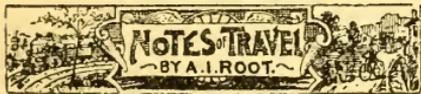

have such fellows prowling and succeeding in their work, just as it is a disgrace to have rats and mice in and around your premises. Wake up, and declare with manly energy that these things shall not be; then stick right to it till you get them trapped and the nuisance is abated.

Now for the bearing of the pickpocket story on the case before us. These two fellows, with their countryfied air and cheap ready-made clothing, were *rascals*. They ought to be, and the good of society demand that they *shall* be, speedily locked up, and then converted from the error of their ways. Their calling is a *disgraceful* one; and the matter is so self-evident that you look up in surprise when I say picking pockets is a "disgraceful occupation." But, my friends, these two chaps who aped stupidity are *gentlemen* beside the Oxydonor and Electropoise people. They do not ape *Christianity*—at least, I never heard of a pickpocket so doing; neither do they rob sick people—certainly not as a rule. They get their money from people who are able to go about and do business; and I shouldn't wonder a bit if they would actually blush with shame to be caught charging \$25 or even \$10 for a humbug scientific apparatus advertised in religious papers, and boomed by ministers of the gospel who lack even the rudiments of a knowledge of electricity or chemistry.

Do you ask how we shall abate the nuisance of pickpockets? Well, in the first place have your money stowed away in some place where a pickpocket can not readily get at it unless, indeed, he should knock you down. Then when you go into crowds or places where such fellows frequent, avoid showing money or your pocketbook. I have done quite a little traveling, as you may know, and I always make it a point to have the money for my ticket in my fingers, or in some convenient pocket, before I reach the ticket-office or get into the crowd. Never take out a roll of bills if you can help it, where people are standing around, especially among strangers. With a very little care you can manage to pay all your bills without having a sum of money in sight, or where a pickpocket can get at it. Especially, avoid anybody who seems to be awkward or always in the way. This is an old game. And, by the way, if people generally would take a little pains to avoid standing still in doorways or busy thoroughfares, or in crowded church-aisles, it would be a great help all round. I frequently come pretty near losing all the effect of an excellent sermon because somebody stands in the church-door, and goes neither in nor out, keeping a whole string, myself among them, waiting when I am in a great hurry. Perhaps I too am guilty sometimes of getting in the way of busy people; but I have made many big resolutions to try and not do it thoughtlessly again. I am under the impression that a *woman's* pocket is not the place to put money. I do not believe, either, it is just the thing for her to carry her money in her hands—at least, not very much money. I was just going to tell you where I carry my money in traveling; but it might be a bad plan to give away my secret. In the first place, I do

not have much money. I carry checks of, say, \$25 each, and these I can get cashed at any bank. Then I stow away the \$25 where a thief can not easily get at it, taking out just enough for each day's expenses, when I am in a room by myself—that is, when I am among strangers. Rats and mice won't stay around, and, for that matter, frauds either, unless you bait them with something good that they can get at; neither will pickpockets. Let me modify the latter a little. Go into any town where saloons thrive and make a good living, and *there* you will find pickpockets. The scene I have described happened where a considerable-sized railway depot is planted right in the midst of a hot-bed of saloons. Banish the saloons, and you will get a good way along in banishing the pickpockets.

Now, then, while you are, by precept and example, saying to the saloon-keepers, pickpockets, and all others of that class, as did Paul in the language of our text, "Wilt thou not cease to pervert the right ways of the Lord?" let us also remember the slick persons who mix among Christian people, and get into the advertisers' department of religious papers, and induce ministers of the gospel and other Christian people to help them rob the sick, the suffering, and the dying. Let us cast out these persons who, under the guise of being philanthropists, scientists, and inventors, charge enormous prices for their hypocritical humbug toys. Let us *especially* beware of "false prophets which come to us in sheep's clothing, but who inwardly are ravening wolves."

#### ON THE WHEEL.

After the torrid wave along the fore part of July the weather changed very suddenly; and as I was a little careless about changing my thin attire for one more appropriate for the weather, I took a severe cold and had another attack of malarial chills, or something like it. Of course I thought of my regular cure for such troubles—the wheel; but for two or three days, in spite of the beefsteak, I felt too sick to ride the wheel or to do anything else. However, on Saturday morning, July 17, I was agreeably surprised to meet Mr. E. C. Keck, of Bowling Green, Florida; and as he is interested in gardening, either north or south, I very much wanted to take him to the celery and small-fruit farms in our county. At first I planned to go with a horse and buggy; but I actually felt too sick to ride in a buggy twenty or thirty miles; but finding that Mr. Keck was something of a wheel-rider I said we would start out; and if I could not stand it I would go to the nearest station and return home on the cars. I remember of thinking, after I decided to go, that it was preposterous for me to undertake to go away from home in

such condition. In fact, I had been feeling for some time previously that very likely the doctors were right in saying that I should never be a well man—that I might as well give up planning for any active work during the remainder of my life. Perhaps you have had such thoughts and feelings yourself.

Well, we started off on our wheels. I did not feel any worse during the first ten miles, and, in fact, I did not feel very much better. After we reached the celery-farm I told friend Keck I guessed I had better go over to the station and get home before I was any farther away. After looking over the beautiful plant of Jordan Brothers, however, and asking them questions about this, that, and the other treatment, I soon began to forget my aches and pains. Some little time ago, you may remember, I advised them to try one of the Breed weeders made especially for onions. They got a machine in accordance with my advice. Said I:

"Oh! by the way, how did your onion-weeder turn out? Did you get your money back on the investment?"

He turned around, and, in his peculiar way, lifting his hand as if to add emphasis, said:

"Mr. Root, that onion-weeder paid for itself in *one day*."

I do not know but he added afterward the expression was a little strong; but they really succeeded, as I thought they would, in not only running the weeder lengthwise of the rows, but they pulled it crosswise also. The boys who pulled it could easily step over the onions; and in this manner the ground was pulverized most thoroughly in and around and between the plants.

They were having some trouble by the first early celery sending up seed-stalks. I wanted to get at them myself and pull out the useless plants that were determined to go to seed; but the boss said, something as we have it in the parable, "Not so; for in pulling up the useless plants you will disturb and injure the good ones. Let them both stand till the harvest, which is soon coming, and we will sort out the bad ones as fast as they are gathered."

There was considerable discussion as to whether it was the strain of seed, the unfavorable weather during the spring, or a lack of water at a critical period; and I believe all decided that the latter was the trouble, or at least one of the prime causes of it. The most of this thing happened in the new celery culture where plants are put so very closely together, and, of course, it would need the greatest quantity of water, especially as they approached maturity. Where the plants were in rows two and a half feet apart or more a far smaller proportion had shot up seed-stalks.

They had the handsomest field of American Pearl onions I ever saw in my life; but as they were not started under glass, as our own were, it will be some weeks before they harvest their crop.

They are using, for a fertilizer on the celery rows, bone and potash. They were also sprinkling the beds with quick-lime in order to counteract the effect of blight, which made them much trouble last year. They began gather-

ing and shipping celery about the middle of July.

When we were through talking I told Mr. Keck I felt so much better I thought I would venture to push ahead another ten miles. We had a macadamized road, and the wheeling was grand. When out four or five miles I noticed that I was beginning to draw in long breaths that filled my lungs completely, as I often do in climbing hills. It came natural and easy to fill my lungs clear out to the fullest extent—something I seldom do except when out on my wheelrides. A little later I felt my second wind beginning to reinforce my strength and buoy up my spirits; and when we came near the town of Lodi I had actually forgotten my indisposition. In passing a large raspberry-patch that covered the side of a hill I remarked to friend Keck that it was a part of Prof. W. R. Grannis' raspberry-farm.

A little further along I noticed a board on a gate-post, announcing, "Jersey cow and calf for sale. W. R. Grannis." So there was where he lives at present. We turned our wheels into the lane. The professor himself soon made his appearance, with one of his eyes swollen up. You see I sent him GLEANINGS complimentary a while ago, when I was writing up the raspberry business; and the result was he got to reading about *bees*. Without my knowledge he had also been studying the A B C book; and, sure enough, there was a row of neatly painted hives right along by the dooryard fence. He was going to show us some of the wonderful achievements his bees had been performing with the aid of the clover-fields all around about his pretty home. But we told him we wanted a drink of water before we explored either bees or berries. Said he:

"Well, you just come right into the house, both of you."

"But, friend Grannis, we have not time to go into the house. We will just sit out here in the shade."

"No, that will not do; you have got to come into the house to get the water."

Just then it occurred to me that Prof. Grannis and Dr. C. C. Miller are in many respects a good deal alike. They are both godly, both professors of music, both bee-keepers, and both have a quaint way of making you feel acquainted, even if you have never seen them more than two minutes. We followed our host into the house, then we turned into a room adjoining the kitchen. This room was paved with stone flagging; and right out from the stone wall in the further corner there came a stream of crystal water nearly as large around as your wrist. It poured into a large trough or vat, circulated around among the pans of milk, and passed out at another corner of the room.

"Why, friend Grannis, do you really mean to say that this is *spring water*, and that it runs that way nights and Sundays and all the year round?"

By way of answer he extended a drinking-glass, and told us to taste and see—beautiful cool spring water right out of the sandy rock in the hillside. After leaving his house the wa-

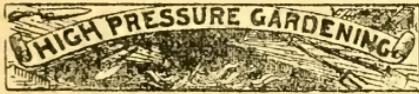

ter flows through the barn, treating all his stock to a running stream, then it extends a little further to a trough by the wayside, where it refreshes the thirsty traveler and his beast. After we had drank sufficiently I wanted to wash my hands. While doing so some tame goslings came up and began to talk as if they wanted to get acquainted. May be you think it queer to hear me speak of goslings that could talk. Well, they did talk, and quite entertainingly (to me). The professor explained that they wanted me to hold down the wash-basin so they could get a drink. Then they wagged their tails and expressed their satisfaction as only a gosling knows how to do. You see, while friend Grannis enjoys himself with the berries and the bees his good wife raises ducks, chickens, and geese; and with this abundance of spring water, every thing goes on "swimmingly." I use this word after mature deliberation, and I think it is the right one. Well, I found so much to entertain me around that pretty home that we were urged to stay for supper. Friend Grannis promised us some white-clover comb honey, which he thought we did not often find. I told him I did not care so much about the supper, but I felt sure I should get home with much more satisfaction if I could have a nap of fifteen or twenty minutes, for you see I had not had one at all that day, and I considered myself an invalid besides, or at least I did so consider myself when I started away in the morning. I had forgotten to say that, some time during the visit, we looked over the fence and got at least a very good "glimpse" of the eleven-acre field of raspberries in full bearing, and I suppose that is the reason I did not want any raspberries for supper. I looked at them so long over the fence that I got over being raspberry hungry. See? They were Greggs, and just ripe enough to be luscious. Did I tell you I was on the beefsteak diet? Well, when I am off wheel-riding I leave my special diet at home.

If I remember correctly, friend Grannis is a professor of music; but of late I think he must do a great deal as I do—drop his mantle over his children's shoulders. When we were shown into another room after supper, and heard his grown-up daughter play, while Miss Lottie, only ten or twelve years old, sang to us, I really felt *ashamed* of myself to think I had not in the morning faith to believe that God in his great mercy had in store such exquisite happiness as I then and there enjoyed while listening to that music. The first piece was called "Dear Heart;" and if you have never heard it, please do not miss it when opportunity offers. The next piece was called "The Holy City." We call it "Jerusalem" for short. I shouldn't wonder if I enjoy music rendered by childish voices, in a way that I never shall and never can any other. And, again, that second wind that I get in wheel-riding gives me a zest, not only for a good supper, but for music, painting, oratory, literature, or any thing else.

When we started for home the sun was but little more than an hour high, and my special errand to Lodi was to investigate the new oil-

works. Ten years ago or more they drilled for gas, and found a stream large enough to light the home of one of the owners, very fairly. Some time last winter the pipes began to send out *oil* instead of gas; and now a great derrick and immense pumping-engine are being put in place in order to gather the oil.

We reached home about eight o'clock in the evening. Our people were gathered out on the lawn; and, when I began, with great animation, to tell about our wonderful trip and its enjoyments, somebody asked about my sore throat and malarial chills. At first I did not exactly understand; and when I said, "Why, let me see! *was* I sick when I started away this morning?" they burst into a loud laugh; for, to tell the truth, I reached home in such exuberant spirits I actually had forgotten my experience of the fore part of the day; and I am afraid, dear reader, I had forgotten, till that moment, to give God the praise.

#### GROWING STRAWBERRY-PLANTS.

I have before explained many times why it is that a well-rooted young plant in July is worth ever so much more than one later. It is a good deal like the old adage—

A swarm of bees in May  
Is worth a load of hay;  
A swarm of bees in June  
Is worth a silver spoon;  
A swarm in July  
Is not worth a fly.

But the way honey has been coming this summer, and that, too, during the last part of July, makes me inclined to think that a swarm of bees in July might this season be worth considerable after all. Well, a strawberry-plant put out in July may make two good plants in August; four by September; eight by October, and sixteen by November. If you have the plants in beds, and put on sashes, you may make thirty-two by Christmas. Again, if you keep off all runners, and just make the plant grow big and stocky, you may get a whole quart of berries from a plant that has not been located even one year. For the reasons just given, we *push* plant-rearing during this month. In fact, we have been shipping plants at a lively rate every day for several days back. Now, how shall we manage to get good stocky plants with the least expense and trouble? There is no better way to start them than the one laid down in the strawberry-book. Set out your plants in the spring in good rich ground well fined up, in rows four feet apart, the plants being two feet apart in a row. By July, if you have done your part with the cultivator and weeder and hoes, the plants will be setting considerably. Some say, keep the runners off till the plant gets strong; but this would deprive you of your early plants.

If, then, we are going to make the most of these early plants, how shall we manage to

keep on cultivating, stirring the soil, and keeping out weeds? A problem besets us right here that I have discussed many times in these pages. The trouble is to find a man or boy who will put the runners in place so as to have them crowd each other as little as possible, and at the same time not get out into the row in the way of the cultivator. I have explained the thing over and over to men and boys whom I considered bright and intelligent. I have even made drawings on a board of what I wanted, and told them to take the board along down in the field; but I have been obliged to give it up in despair. When I go to look over the work I find runners rooted sticking right straight out into the row where the cultivator could not get through without digging them up. Then I would find three runners on one side of a plant, crowding each other, and not a runner at all on the other side. The plants would be altogether too close for thrifty growth in one spot, and great glaring vacancies where they might and should have been put. Some runners will grow a foot or more before making a bud for the plant; others will grow three or four inches. Now, the long ones should be made to fill the vacant spots that need filling, and let the short ones take the next best place. I suppose nobody else *loves* strawberry-plants as I do, and that is one reason why nobody else gives the matter sufficient thought and attention to make it a success.

Well, now, I have hit upon a little device that has enabled me to give my plants space in very good shape, and at comparatively small expense. When they began to put down runners on the Brandywine and Wm. Belt rows, I called two of my good boys, Carl and George. We first stretched a string just as near the row of plants as we could have it and still give room inside the string to set all the runners. Then the boys were given two trowels to break up the crust between the plants where the cultivator could not go, and make it all mellow. Then they put the runners down, placing a little dirt with the trowel over and around the bud, making each plant go inside the string. They thought I might give them a little more room by putting the string further away; but I told them we would put it further off next time. They got them all in nicely, leaving a space of five or six inches between every two plants. Then they took a hand-hoe and cultivated the ground up soft and fine clear up to the string. The string was then moved to the other side of the row, or, rather, two strings were used, one on each row of berries, leaving a path from 15 to 18 inches wide between the two strings. Here the boys stood (or sat down) while putting the plants in place.

After the row was finished, of course so much walking on the path would make it hard from the stamping. The boys therefore always went through with their wheel-hoe, and fined it up again. After the boys had finished their work, a nice shower of rain came up, and every plant they had put down was soon rooted, right where they put it. It was indeed a pleasant sight to behold, especially as the edge of the bed where the string was stretched

was as straight as a line. A man could go in with a horse (and, in fact, did go in with a horse), and keep the space between the rows beautifully fined up and keep down all weeds.

Well, we are just now doing the same thing out in the field. A string is stretched each side of the row just as close as the stage of growth will allow. The plants were all made to go inside of this string. Vacancies that can not well be filled otherwise are fixed with the transplantor.

You may say it is lots of trouble to put every runner down by hand where you want a plant to grow; but I believe it is less trouble than to have your rows in certain places so wide that scarcely a path is left. A man who has any taste and skill at all will go into a nice strawberry-patch made as I have directed, and run his fine-toothed cultivator clear up to the point where the string was stretched, and will do you a handsome job. If you are selling plants, you get ever so much better roots to have the ground evenly occupied. Now try it, and see if my invention in strawberry-growing is not worth something, even if said invention is not (when you come right down to it) any thing more than a ball of string that costs only a nickel.

#### THE GAULT RASPBERRY.

Several have inquired why we have had so little to say of late about the everbearing raspberry. Well, we stopped selling plants some time ago because there was so much difficulty in getting them to grow. We have in some cases sent them the second or third time, and even then failed. Another thing, all of the blackcap raspberries on our grounds are affected more or less with anthracnose. Either of these reasons would be sufficient, perhaps, to explain why we no longer offer them for sale. One or two have been unkind enough to pronounce them a humbug. One of our clerks, while dictating a letter to one of these friends, remarked that, if the man could see the Gault raspberries in her mother's garden, he would never think of calling it a swindle. Our two boys, Frank and Fred, have just informed me that they have succeeded excellently with them at their homes. One or two have complained that they do not bear a second crop, and I believe this second crop sometimes fails to show up until the plant gets to be strong and vigorous. I think it is true, however, that, like many other new things, it does not seem adapted to *all* soils and all locations. This we find true with all sorts of berries, especially strawberries. The Jessie does wonders with one person, and with the next it does not seem to amount to any thing. Don't be in haste to claim you have been swindled because certain new fruits do not always do well on your grounds.

#### THE CRANDALL CURRANT.

We have just received from H. L. Wise, Berkeley Springs, W. Va., some twigs by mail, loaded with Crandall currants, so large they look more like cherries than any thing in the currant line; and yet, from my own experience with a single plant which I have in my garden, I might claim I had been humbugged.

#### THE LOGAN BERRY.

This blackberry-raspberry has given us a few berries this year about as large as a good-sized blackberry, and as luscious, I should say, as any red raspberry. It is a very strong grower, and promises to be a desirable acquisition. The strawberry-raspberry, however, has not yet amounted to any thing in the way of fruit. Our June-berries have this season given us a good crop of most luscious berries. The birds take such a shine to them, however, that we had to fight for them after the birds discovered where our group of bushes was.

#### POTATO-BUGS, PARIS GREEN, ETC.

During the severe hot weather along the fore part of July, potato-bugs started out with almost unprecedented vigor. Hundreds of potato-growers found their vines almost stripped before they knew there was a bug in the fields. In fact, so great was the demand for Paris green that we received the following letter from one of the largest wholesale drug-stores in Cleveland:

*Gentlemen:*—As we are sold out of Paris green, and unable to procure in this city, and failed in our efforts to get a portion from Buffalo, Detroit, Columbus, and Toledo, we are in no position to serve our friends for this commodity. STRONG, COBB & CO.  
Cleveland, July 13, 1897.

We at once sent our order to New York, and got it filled promptly. Now, there is pretty sure to be a chance to learn something useful during all these extremes of temperature—or, if you choose, unexpected happenings. When we were sold out of Paris green we tested a great variety of "bug-powders," including slug-shot, buhach, hellebore, mineral ash, etc. While each and all of them do some good, there is nothing that approaches pure Paris green applied with the bellows made for that purpose; and there is nothing so sure and quick-acting, and nothing so cheap. That is my decision. A good many of these things kill by contact, and, for that matter, common road dust I have sometimes thought almost as good for the potato-bug larvæ, or slugs, as many of the expensive remedies. When they are greasy and shining, and covered with a sort of sticky liquid, any sort of dust, if there is enough of it to put on, is death to them. If this is alkaline, like mineral ash, or pungent, like slacked lime, perhaps it is somewhat better; but I do not believe potatoes make good progress when their foliage is covered with dust. A dusting of Paris green so slight that it can not be seen by the naked eye is death to the bugs; and if it does not rain, this same foliage is death to every insect that begins to gnaw the leaves.

Now just a word about prices on Paris green. It is all right for druggists to charge 10 cts. an ounce for things that cost them only 10 cts. a pound, where the article is called for only once in a while, or where they have to furnish a bottle and cork, or something of that sort; but to charge 35 and 40 cts. a pound for Paris green, when it may be had wholesale for 14 or 15 cts., is not Christianlike nor businesslike, in my opinion. Paris green has come to be a great staple. Farmers must have it, and they can not afford to pay great prices. My 100-lb.

shipment cost me in New York 13 cts. per lb., and I can easily put it in ¼-lb. packages and sell them for 7 cts. each, or a whole one-pound tin can for 22 cts., and we can furnish absolutely pure Paris green at this price. Now, I am not mentioning this to advertise it, but to advise you to purchase it at your nearest drug-store. Show this article to your druggist, and I think he will agree to furnish it at these prices, and I will tell him where to buy it if he wishes me to do so.

In the *Rural New-Yorker* I notice some discussion as to why the bugs are worse on some varieties of potatoes than on others. The *Rural* says, and with much truth, that the bugs pitch into the potatoes latest planted. This is true until you come to potatoes planted in July, that come on after the worst of the bug season is over. I have seen acres of such potatoes with not a bug to be found. By the way, there is a good prospect that the great raid of bugs is going to make potatoes scarce and high-priced; at any rate, it will pay the potato-grower to watch his vines closely. With a good gun (or bellows), and plenty of good Paris green, it is not a very expensive job to keep the bugs off entirely; and if you kill them thoroughly one season you will find it much easier to fight the battle the season afterward. One thing more:

There are certain varieties of potatoes that are much less liable to be troubled with bugs, and I believe it is, as a rule, the rank strong growers, especially among the late potatoes. Manum's Enormous and Craig are troubled but little, comparatively. Years ago we noticed that the *Rural New-Yorker* was not troubled nearly as much by bugs as the other kinds. I am sorry to say that the Thoroughbred seems to be especially picked out by the bugs.

#### MY GOOSEBERRY STORY.

Gooseberries have been rather slow sale now for two seasons; yet we have sold quite a few this summer at 5 cents a quart. I thought at first this was a rather low price, and was questioning whether it paid, so I made a little investigation. Two or three years ago I thought I should like to see what gooseberries would do down on our very rich creek-bottom land, where every thing goes to vines and foliage. So I moved seven or eight gooseberry-bushes down there and watched for results. Last year one of the bushes grew taller than my head, and bore a pretty fair crop of berries. This season it was once more loaded with berries. In fact, the tall bushes bent clear over and rested on the ground. This bush has already given us a peck of berries, and there is certainly another good peck to be picked. I think the variety is the Houghton, but the bushes are very tall and spreading. There are no thorns on the bush or on the berries; and this is a matter of some moment also, because, where there are no thorns in the way, you can hold a basket under the branches and strip the berries right off. I think one could easily strip off every berry in this way in half an hour. In fact, it ought not to take more than a quarter of an hour. But we will estimate the crop from the one bush at half a

bushel, and the cost of picking at 5 cts. That leaves 75 cts. profit for a single crop on one gooseberry-bush. This seems almost incredible; but there is the bush with half of its crop remaining. Besides the peck that has already been picked I have helped myself quite liberally, and advised my friends to do the same, several times. They are just now ripe enough to eat. I begin to think one reason why we have not sold our gooseberries better is because we have not sold them cheap enough. If a market can be found for them when canned, there is a tremendous chance for a gooseberry-farm. They are not perishable; and there is so little danger of bruising in handling, that, when they are gathered green, they might be sent to market in a bag; and the bag, if it did not contain too many berries, might be carried on horseback. Then there is an opening for gooseberry jam and gooseberry jelly. Can anybody tell us more about it?

*Mr. Root.*—I should like to have Dr. Miller tell whether sweet clover does as well if sown in the fall as in the spring; also your opinion, and whether it has to be sown every two years, as some claim.

Luce, Mich., July 23. WM. CRAIG.

I can only answer for myself, that I know nothing about it; but I know that the seed that drops off in the fall comes up the following spring. We have not sowed any sweet clover anywhere for a good many years, and we never sowed any along the fence-corners and waste places, although we have been many times charged with so doing. Will Dr. Miller please answer?

### Special Notices in the Line of Gardening, etc.

By A. I. Root.

#### A "DARLING" STRAWBERRY-PLANT FOR EVERY DOLLAR SENT US FOR GLEANINGS.

As we think the Darling is sure to please, and as we want all of you to see one of our "new-process" potted strawberry-plants with the jadoo fiber, we have decided to send one plant free, postpaid by mail, to every one who sends a dollar for GLEANINGS during the month of August. Here is what the originator, M. T. Thompson, Rio Vista, Va., says about the Darling: "If there ever was a berry that would produce 1000 bushels per acre, it is this one. It is a seedling of Michel's Early, and has fruited for us two years. Price of plants, \$3 per dozen."

#### STANDARD STRAWBERRY-PLANTS.

We are now prepared to furnish the old standard varieties of layer plants at our old prices as follows:

10, 15 cts.; 75 cts. per 100; \$6 per 1000. If wanted by mail, add 5 cts. for 10, 25 cts. per 100, for postage. The varieties that we now have ready to send out are Jessie, Parker Earle, Michel's Early, Warfield, Bubach, Edgar Queen, and Haverland. Please notice we are not yet prepared to send these out in quantities during the present month larger than 10 or perhaps 100 of each kind; and if many orders should come in, yours is likely to be delayed until they get to be better rooted. These older varieties can be potted by the new process at a cost of one cent each extra, and a delay of ten days or two weeks of time, for we shall pot the old standard varieties only after they are ordered.

#### GOVERNMENT AGRICULTURAL REPORT FOR 1896.

The Year-book for the Department of Agriculture for 1896 is the most valuable publication I have ever come across among the government reports. It is a book of nearly 700 pages, profusely illustrated with beautiful pictures touching upon many points of intense interest to farming, gardening, and other branches of agriculture. Among the subjects treated

are steam-apparatus for spraying; potash, its function in agriculture; irrigation on the great plains, including pictures of home-made windmills; seed-production and seed-saving; migration of weeds; cow peas; improvement of our native fruits; planting waste places; asparagus-beetles, etc. Of this book 100,000 copies have been printed. You can get one free by writing to your Representative in Congress.

ASPARAGUS-BEETLES.

For many years I have read about asparagus-beetles, in our various agricultural papers, but rejoiced that we had never known an enemy to the asparagus in our locality—beetle or any thing else. A few days ago, however, one of the boys called my attention to the fact that one of our asparagus-patches was literally stripped of its foliage by a bright handsome little bug and a sort of worm that followed it. They seemed to work exactly like the potato-beetles, bugs and larvae right along together. We brought out our gun for dusting dry Paris green, and both bugs and larvae quickly "tumbled to the racket," as the boys say. Now then, look out, just as soon as you see a dozen of these bugs (and you may know them because they are such good-looking rascals) on your asparagus you had better commence dusting, wherever you see them, with Paris green. The government report I have mentioned recommends dusting them with dry quicklime, which may answer every purpose. The above report estimates that in York State, where asparagus is largely grown, this beetle did \$50,000 damage in just one county. Chickens will eat them readily if the bushes are shaken or cut down so the chickens can reach them. Whatever you do, do not let them go on until your prospects for an asparagus crop next spring are ruined.

TRANSPLANTING STRAWBERRIES.

I have just made a discovery in connection with the use of that jadoo fiber I spoke to you about last month, that I think is going to prove of very great value in disseminating new and high-priced varieties of strawberries. All the vegetable-plants we send out are, as you know, either once or twice transplanted. The transplanting is mainly that we may get a mass of good strong bushy roots. Now, I have for years felt that it would be exceedingly desirable if we could do this with strawberry-plants, say along in July and August. A great many times where you send them out thus early there will be a large showy top and comparatively few roots. Of course, you can pull off the greater part of the leaves, but this does not answer the purpose as does transplanting. Now for my invention:

Potted strawberry-plants are no new thing, as you well know; but there have always been two troubles with them; namely, they can not be sent by mail because the moist earth is too heavy; and if they are not taken up and shipped as soon as the roots fill the pot, they will soon be pot-bound.

The jadoo fiber has proved to be a wonderful success. If the pots are packed with this material, the roots of any strawberry-plant will, in an incredibly short space of time, permeate the whole pot; and the jadoo fiber is so light that, with a proper amount of moisture, half a cent will pay the postage on a plant. Another thing, it holds the moisture better than any thing else I ever saw. So you see we have succeeded in sending potted plants by mail, including the soil that filled the pot. There is no need of sending the pot along with the plants, because the jadoo fiber holds together so well, especially when permeated by the strawberry-roots, that it can not be easily shaken off. I have tumbled the plants around, and taken them out of the pots dozens of times, even during the hottest days, and have fully demonstrated that they stand any amount of handling without even having the foliage drop.

Well, I have done pretty well, haven't I? But the most important part of my discovery is yet to come. It is this: Just as soon as your pots are full of roots, sever them from the parent plant; slip them out of the pots, and set them out in regular plant-beds spaced, say, three or four inches apart. They can be shaded and watered in this plant-bed if necessary; but unless the weather is severely hot, I do not think shading will be needed. In three or four days little white roots will shoot out in every direction from this ball of jadoo fiber. In fact, some of our little plants have sent out little white roots in such numbers that it looks almost like the hairs on a frightened pussy cat; and every gardener and florist, when he sees these new white roots, knows his plants are in the best possible condition. I need not tell you that our plant-

beds are made exceedingly rich, so that every thing grows under high pressure when it starts out.

Now, my dear friend, how much more do you suppose such transplanted potted plants are worth than the ordinary layer plants, especially for fall planting? I am so anxious to have you see what they are like that we will send you one or more plants postpaid by mail at the following prices:

PRICES OF TRANSPLANTED STRAWBERRY-PLANTS FOR THE MONTH OF AUGUST.

| NAME.                       | Each | 10     | 100   |  |
|-----------------------------|------|--------|-------|--|
| Darling.....                | .25  | \$2 50 |       |  |
| Carrie.....                 | .20  | 1 75   |       |  |
| Earlie G. M. Doolittle..... | .20  | 1 75   |       | Any of these will be 1 cent per plant less for layer plants. |
| Nick Ohmer.....             | .15  | 1 50   |       |  |
| Margaret.....               | .10  | 1 00   |       |  |
| Marshall.....               | .06  | 40     | 23 50 |  |
| Bradwin.....                | .06  | 40     | 3 50  |  |
| Wm. Belt.....               | .06  | 40     | 3 50  |  |

All the varieties above, except Carrie, are perfect. At the above prices we pay postage or express charges. Where there is an express office near your home, we prefer to send 50 or more by express.

CONVENTION NOTICE.

MR. EDITOR:—The next annual convention of the United States Bee-keepers' Union will be held in the main hall of Canton's Business College, corner of Clinton and Huron Sts., Buffalo, N. Y., commencing at 10 o'clock A. M., August 24th next, and closing on the afternoon of the 26th.

Papers are to be read by W. Z. Hutchinson, R. F. Holtermann, E. Whitley, Hon. R. C. Fowler, Mrs. L. Harrison, R. C. Aikie, G. M. Doolittle, Dr. P. H. Brown, Hon. Eugene Secor, G. W. Brodbeck, M. B. Holmes, A. E. Mann, E. Kretschmer, and P. H. Elwood; to which will be added the President's Address; and perhaps the General Manager and the Secretary may have something of interest to present.

The programs are now printed, and are in the hands of the Secretary. There are six bee-keepers' songs, with music, in the program, and abundance of time is allotted to the discussion of all papers, and for the asking and answering of questions.

Any one not a member of the Union can have a program sent him by mail on receipt of 5 cents in stamps, by the Secretary. Several of our well-known bee-keepers, such as A. J. Root, Dr. Miller, S. T. Pettit, and others, who are not on the program, will be present to help make the convention interesting and instructive.

It is probable that suggestions will be made at this convention in the line of so amending the constitution of the Union as to remove its objectionable features and add such other provisions as may seem desirable; and suggestions in this line by those not able to be at the convention can be sent to the Secretary, to be brought before it. Some suggestions have already been received by the Secretary, and others have been made in the bee-papers.

Those going to the convention should buy round-trip tickets to the Grand Army of the Republic encampment (not to the United States bee-keepers' convention), which meets in Buffalo during the last week of August. The G. A. R. have secured a rate of one cent a mile each way in the territory of the Central Passenger Committee, which is included by Toronto, Canada, thence on a line to Port Huron, Mich.; all of the southern peninsula of Mich.; Chicago, Peoria, and Quincy, Ill.; St. Louis, Mo.; Louisville, Ky., and Pittsburg, Pa. The Western Passenger Association and the Trunk Line Association make a rate of one fare for the round trip in their territory, to places in the Central Passenger Association, from which points the fare will be one cent a mile each way; but tickets must be purchased to Buffalo from the starting-point. Inquire of your ticket or station agent in all territory outside of those named above for rates and the time the tickets are good for, for I have been unable to learn the rates in such territory, but presume will be the same as those of the Western Passenger and the Trunk Line Association; but be sure to inquire of your ticket agent, as above suggested.

In the Central Passenger and Trunk Line territory, tickets will be good for 28 days, 25 cents; and, if vised at Buffalo, will be good, returning, for 30 days.

Mr. O. L. Herbsier, of Buffalo, has charge of arrangements at Buffalo, and will attend to the matter of hotel rates. Mr. H. will be glad to furnish the accommodations in private families for all bee-keepers who prefer such to hotels. Members of the Union can learn in regard to hotel rates by applying to the Secretary at the place of meeting. If known in time, hotel rates will be given in the bee-papers.

A. B. MASON, Sec., Station B, Toledo, O.

The annual meeting of the Northern Illinois Bee-keepers' Association will be held at the Court-house, in Freeport, Ill., on Tuesday, August 17, 1897. All are cordially invited.

B. KERSEY, Sec., New Milford, Ill.

FOR SALE--140 Colonies Bees.

With fixtures up to date. Three hundred extra hives. Also ten thousand pounds of honey—this season's crop. Part of honey is in one-pound sections and remainder extracted, and to be. Bargain for some one.

Yours for business,  
ANTHONY OPP, Helena, Ark.

Are You Going to Buy 

### Apiarian Supplies or Bees?

If so, You Want the Best.

This is the only quality we offer. Our prices are right, and our '97 catalog describing them, and the management of bees, is yours for the asking.

We carry a large stock, and can ship promptly. Freight is a big consideration, often amounting to 20 per cent of the value of goods. Let us quote you prices on what you need, delivered at your station.

### Freight Paid.

They will cost but a trifle more than others charge at the factory. Our aim is to please.

Apiary,  
Glen Cove, L. I. I. J. STRINGHAM,  
105 Park Pl., N. Y. City.

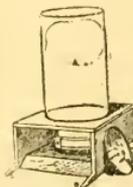

**Queens,**

Either Golden or Imported, by return mail. Untested, 75c; Tested, \$1.; Breeders, \$2.  
W. H. LAWS, - Lavaca, Ark.

### Don't Neglect Your Bees.

Bee-keeping may be made uniformly successful by judicious feeding. It is just as important with bees as with other stock.

Success in feeding depends very much on the feeder used. When you have tried the

**Boardman Atmospheric  
Entrance-feeder**

you will be convinced of this.

For descriptive circulars and price list, address

**H. R. BOARDMAN, East Townsend, Ohio.**

**QUEEN,** (8) cents; three or more, 50 cents; dozen, \$5.50; tested young, 75 cents.

J. B. CASE, Port Orange, Fla.

## BUCKWHEAT AND CRIMSON CLOVER.

The question is often asked, "How late can we sow buckwheat, with a reasonable chance of getting a crop of seed?" The best crop I ever raised was sown as late as the 15th of August; but, of course, much depends upon how early we have a killing frost. You can get blossoms for honey, probably, if sown any time during this month. The best yields of seed are from seed sown in the fore part of August, if the frosts hold off. We have still a good supply of seed in stock.

Now is the time to sow crimson clover all through the North. It may winter all right if sown a month later; but the sooner you get it in, the better. From the amount of home-grown seed that is offered us for sale, I think it has been quite a success all through Ohio during all this past season. Remember, a two-bushel bag of buckwheat is now only \$1.10; and a two-bushel sack of crimson clover is only \$5.50.

## KIND WORDS FROM OUR CUSTOMERS.

STRAWBERRY-PLANTS BY MAIL, POTTED IN JADOO FIBER.

*Friend Root*.—The Nick Ohmer strawberry-plants, potted in jadoo fiber, came to hand by mail in splendid condition. I do not see why it should not prove to be an entire success. I shall be glad to learn more about it. I have an idea that plants potted in the jadoo fiber will thrive much better. The weight is certainly many times less. C. N. FLANSBURGH. Leslie, Mich., July 26.

Having lately purchased your A B C of Bee Culture I can not help writing to state my appreciation of the work. It reads like a romance. You have a way of simplifying facts which attracts the eye and commands the reader's attention. Perhaps I can pay you no higher tribute than to say the reading of your book is alone sufficient to give a novice the bee-fever. Mrs. L. E. R. LAMERIGER. Niobrara, Neb., June 23.

*Mr. Root*.—The strawberry-plants came to-day in perfect order, and are set out, and it is now pouring down rain. I couldn't have received them at a better time. They are splendid plants. With such high-priced plants I did not expect extra ones; but they were there. Many thanks for the same. Nashville, Tenn., July 15. JOE L. COOPER.

[My good friend, I did not know that our boys gave extras with the high-priced plants. Perhaps it was a mistake in your case, or may be one of the plants was small. I have thought best to mention it, so that others might not expect us to send more strong plants than we really advertise.—A. I. R.]

[The following comes to us on a postal card. What do you think of it?]

Millions of our farmers have been destroyed, soul and body, by our legalized saloons and open harlot-houses, and millions more are paralyzed by them so they are worthless. And millions of homes are desolated, and millions of acres are turned out or are not half farmed. And still our authorities force it on us to rob and to murder our nation. H. HANSEN. Pasadena, Cal.

## The New Weed Drawn Foundation.

This is a success. Don't take the statement of any one else, but send for samples and try it yourself. Pieces 4 inches square, and running about 11 feet per pound, are now being sent out. PRICES:—3 pieces, 4x4, 10c; by mail, 12c. 10 pieces, 2x5; mail, 30c. 24 pieces, 50c; mail, 60c. Half-pound packages at 75c with other goods, or 10c postpaid.

**FRUIT and ORNAMENTAL TREES, SHRUBS, PLANTS, ROSES, VINES, BULBS, SEEDS**

Rarest new, choicest old. Send for our catalogue to-day; it tells it all; an elegant book, 168 pages, magazine size, profusely illustrated, free.

Seeds, Plants, Bulbs, Small Trees, etc. by mail postpaid, safe arrival and satisfaction guaranteed. Larger by express or freight. 43d Year. 32 Greenhouses. 1000 Acres.

**STORRS & HARRISON CO.,**  
Box 331 Painesville, Ohio.

**Ajax**

**Bicycles.**

**Price only \$35.**

We have sold a large number of these bicycles, and they are giving universal satisfaction. For instance, the following letters will explain:

"The Ajax bicycle arrived Saturday in good condition. It is entirely satisfactory in every respect. It is a handsome and easy-running wheel, and has the appearance of one put up for service.

FRANK WRIGHT."

"Laporte, Mich., June 28, 1897.

"The Ajax wheel, Model 37, with baby carrier (Kalamazoo) came all right, and it is really better than I expected; although I have learned that when The A. I. Root Co. say a thing is first-class it is as represented.

THOS. M. TODD."

Payson, Utah, July 8.

We have so much confidence in these wheels that three of them have been and are now in use in the Root firm; and E. R. Root expects to make his bicycle-tour on one of these through the East this summer. They are up to date, have large tubing, wood reversible handle-bars, Morgan & W right double-tube or single-tube tires, with option of gearing and option of height of frames, and a choice of finish.

We will sell these wheels and take in trade beeswax or first-quality honey at market prices. We have only a few in stock; and after those we have on hand are gone we will not dispose of more in trade.

A beautiful catalog, showing these wheels up in full, sent on application.

**THE A. I. ROOT CO.,**

Medina, Ohio.

**HALF PRICE.**

After June 10th we sell eggs from all our yards at HALF PRICE (\$1 per 15). Eggs will be from our best pens, and handled with the same care as early orders receive. Our breeds:

**Barred & White Pl. Rocks, Lt. Brahmas, Langshans, Bl. Cochins, White Wyandots, Brown & Buff Leghorns, Pekin Ducks.**

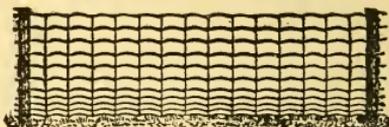

Our stock will surely please you; order now.

**POULTRY SUPPLIES.**

We are America's Headquarters. Biggest Stock, Lowest Prices, Quick Shipments.

NISSLY'S POULTRY ANNUAL and catalogue of "EVERYTHING FOR THE POULTRY YARD" is a book of 80 6x9 pages, finely illustrated and full of information. The book is FREE TO ALL, but we request a 2c stamp for postage.

**GEO. J. NISSLY, Saline, Mich.**

**No Expense For Threshing.**

There is a simple little machine on the market, which can be had for \$1.—, with farm right to use it. This tool was named "flail," but if it is called "hurricane," the work will be easier. The farmer's time is nothing, and after threshing is finished, he can buy a little "pocket whirlingig" and build fence. Of course the progressive farmer will not try to compete with steam, either in threshing or fence building. He uses the PAGE.

PAGE WOVEN WIRE FENCE CO., Adrian, Mich.

**ONE MAN WITH THE UNION COMBINATION SAW**

Can do the work of four men using hand tools in Ripping, Cutting off, Mitering, Rabbering, Grooving, Gaining, Dadoing, Edging up, Jointing Stuff, Etc. Full Line of Foot and Hand Power Machinery. Sold on Trial. Catalog Free. 1-24ei

Seneca Falls Mfg. Co.,  
44 Water St. Seneca Falls, N. Y.

Read what J. I. PARENT, of Charlton, N. Y., says—"We cut with one of your Combined Machines last winter 50 chaff hives with 7-inch cap, 100 honey-racks, 500 broad frames, 2,000 honey boxes, and a great deal of other work. This winter we have doubled the amount of bee-hives, etc., to make, and we expect to do it all with this saw. It will do all you say it will."

Next Annual Meeting at Buffalo, N. Y., Aug. 24—26, 1897.

Honey Column.

CHICAGO.—The offerings of comb honey are in excess of the demand, which of course is quite limited at this season of the year. The receipts also consist of small lots, it being the idea of some shippers to feel of the market by sending a little quantity and waiting for results. Then, again, others have just got a little ready, and sent that pending the time when larger consignments will go. As a rule, in large markets, small consignments will not sell as readily, nor for as much money, as a large, even-running lot. Fancy white comb commands 12c; No. 1, 10@11; no dark offered; extracted white, 5@6; amber, 4@5; beeswax, 2@27.  
 K. A. BURNETT & CO.,  
 Aug. 7. 163 South Water St., Chicago, Ill.

MILWAUKEE.—There are no special features of interest to bring out prominently regarding this market for honey. The supply is quite good—some old crop and some new. Have already received both of the extracted and comb. The demand is very small just now, although we are quite confident later the trade will be good, and prove a proper market for your shipments. Can now quote 1-lb. sections of white No. 1, at 12@13; No. 2, 8@10; dark, 7@10; extracted in barrels and kegs, white, 5@6; dark, 4@5; beeswax, 25@27.  
 A. V. BISHOP & CO.,  
 Aug. 7. Milwaukee, Wis.

NEW YORK.—There is some demand for new-crop white, and some lots received sold at 10@12. Prices are not settled, and this is not a criterion of our market, which actually does not open up until about September 1st. Extracted—market quiet and easy, with large arrivals from the south and California. We quote California light amber at 1 1/2@1 3/4; California white, 5@5 1/2; Southern, 5@5 1/2 per gallon, according to quality. Beeswax without change.  
 HILDRETH BROS. & SEGELKEN,  
 Aug. 9. 120-122 W. Broadway, N. Y.

BOSTON.—New honey is coming very slowly as yet, but as the demand is light there is ample supply. Very little old here. We quote our market on fancy white at 13; No. 1 comb at 11@12; no sale or inquiry for any dark. Extracted very light demand—prices for white, 6@7; light amber, 5@6; beeswax, 27.  
 BLAKE, SCOTT & LEE,  
 Aug. 7. Boston, Mass.

ST. LOUIS.—Fancy white comb, 12@12 1/2; No. 1 white, 11@11 1/2; amber, 9@10 1/2; dark, 5@8 1/2; extracted white, 5@5 1/2; amber, 4@4 1/2; dark, 3 1/2@4; beeswax, prime, 21; choice, 24 1/2@25. Since our last quotations, one car, 24,000 lbs., has been sold at above quotations. With present prices on sugar, think there should be a good demand for extracted honey.

Aug. 9. WESTCOTT COMMISSION CO.,  
 213 Market St., St. Louis, Mo.

CLEVELAND.—Very little new honey in the market. The demand for new honey this past week was fairly well this early in the season. No demand for old white honey whatever. Fancy white, 12 1/2@13; No. 1 white, 11@12; white extracted, 6@7.

Aug. 10. A. B. WILLIAMS & CO.,  
 80-82 Broadway, Cleveland, Ohio.

PHILADELPHIA.—Extracted honey arriving freely; also some very nice comb. Honey-buyers are slow to take hold, as they are looking for low prices, and are holding back for large arrivals later on. We quote No. 1 comb white, 10; fancy comb, 11@12; extracted amber, 4; white extracted, 5@5 1/2. We are producers of honey, and do not handle on commission.

Aug. 9. WM. A. SELSER,  
 10 Vine St., Philadelphia, Pa.

DETROIT.—White comb honey 10@12; very little dark offered; extracted white, 5@5 1/2. Beeswax, 25@26.  
 Aug. 10. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.—There is a fair demand for choice white comb honey at 11@13, with a good supply. There is a very good demand for extracted honey at 3 1/2@6, according to quality. We have, perhaps, never disposed of as much honey at this time of year as we did this season. Demand is fair for bee-wax at 20@25 for good to choice yellow, with a fair supply.

Aug. 10. CHAS. F. MUTH & SON,  
 Cincinnati, O.

FOR SALE.—A lot of good extracted clover honey in 60-lb. cans.  
 JNO. A. THORNTON, Lima, Ills.

WANTED.—To buy quantity lots of fancy comb honey in non-drip cases.  
 B. WALKER, E'ait, Mich.

FOR SALE.—Fancy extracted in 60-lb. cans, and fancy comb (Danz sections) mangrove honey in 30-lb. cases. Cash offers wanted, f. o. b. here.  
 H. PRICE WILLIAMS, Miami, Florida.

ORDERS filled by return mail for the choicest untested Italian queens at 60c each. Can furnish one, two, and three frame nuclei. A. I. ROOT COMPANY'S SUPPLIES. Send for 36-page catalog.  
 JOHN NEBEL & SON High Hill, Mo.

QUEENS. I have 500 untested, 3 or 5 banders, 45c each; tested 3-banders, 70c each. They are fine large queens, and are free from all diseases. Write for wholesale prices. M. O. office.  
 DANIEL WURTH, Falmouth, Kush Co., Ind.

THE A. I. ROOT CO'S  
 Shipping-cases for Honey,  
 AT THEIR PRICES—THE FINEST MADE.  
 CASH FOR BEESWAX.  
 M. H. HUNT, Bell Branch, Mich.

Look Here! Do you need queens? the purest and best. If so, we are prepared, by return mail, to ship the 3-band and golden Italians, and silver-gray Carniolans, untested, warranted purely mated, for 50c; tested, 75c; breeders, \$2.25.  
 JUDGE E. Y. TERRAL & CO., Cameron, Texas.

Tested Adel Queens. Fifty Cents Each.  
 My new (1897) book on queen-rearing, giving a method for rearing queens in a brood-chamber while the queen is present, will be mailed free to all who purchase queens.  
 Henry Alley, - Wenham, Mass.

# A Tested Queen and the Review for \$1.50.

I have a large number of nuclei containing fine tested Italian queens of this year's rearing, and have decided to use them in helping to build up the circulation of the **Review**; hence offer a queen and the **Review** one year to *new* subscribers for only \$1.50. **Review** alone, \$1.00; queen alone, \$1.00. If several queens are wanted, write, and the price will be made according to the number. As a rule, orders are filled by return mail, and there is never a delay of more than three or four days, and that on large orders.

W. Z. HUTCHINSON, Flint, Mich.

## Honey Leaflet

Dr. C. C. Miller.

Why honey is more wholesome than cane sugar.

Honey as an article of diet; honey cooking recipes.

This leaflet is written for the benefit of consumers, and is put out at an extremely low price so that honey-producers may distribute them free to their customers. Prices: 10, 5c; 100, 20c; 500, 75c, all postpaid; 1000, 75c, carriage extra.

# GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

Published by THE A. I. ROOT CO. MEDINA, OHIO.

\$1.00 PER YEAR

VOL. XXV.

AUG. 15, 1897.

No. 16.

## STRAY STRAWS

FROM DR. C. C. MILLER.

GLEANINGS looks very neat in her new suit. Easier to read too.

WIESBADEN is where the big convention of German bee-keepers will be. Wish I could be there!

ALFRED AUSTIN, England's poet laureate, is a member of the Kent Bee-keepers' Association—not an honorary member, but pays his subscription.

ANTS IN HIVES. M. Guilleminot, in *L'Apiculteur*, says he is successful in getting rid of ants by first removing what he can of their nests, then sprinkling well with finely crushed soot.

DID YOU EVER NOTICE that, in enlarging the brood-nest, the queen often lays first on the side of a fresh comb furthest from the brood-nest? I wonder why. [I never noticed it.—ED.]

TO THE QUESTION, whether it is possible and desirable to increase the length of tongue in our bees, nearly all repliers in *A. B. J.* agree as to desirability, and a large majority believe it possible.

THE BELGIAN GOVERNMENT has issued an order that all railway embankments shall be covered with honey-plants.—*Bienen-L'ater*. May be that will happen here, if government runs the railroads.

BYRON WALKER is right about "even thickness of combs." The fact is, I'm so used to thinking of separators being used that I never thought of the great unevenness there might be without them. He's right, too, in thinking there may be too great economy of words in describing grades.

YOU ARE RIGHT, I think, Mr. Editor, p. 550, in thinking the bees would not have so readily capped over that honey if I had taken away all the brood-frames, leaving only full frames of honey; but there was no "putting-in of the frames of foundation in alternation," as you mention. It was frames of brood alternated with frames of honey.

IN REPLY to Mr. Craig's question, p. 573, I think fall is better than spring for sowing

sweet clover, and it most surely must be sown or self-sown every two years, for, like a parsnip, it grows one year without blooming, blooms the next year, then dies root and branch. So if bloom is wanted every year, seed must be sown or self-sown every year.

PROF. COOK favors a return to the old plan of having a few bees on every farm, rather than large apiaries in the hands of specialists.—*Rural Californian*. Which may and may not be all right if every farmer would keep bees. But if all the specialists were killed off, would it at all increase the number of farmers who keep bees?

MANY THANKS, friend A. I., for giving fits to the electrical thieves that are worse than pickpockets, and especially to their aiders and abettors, the religious press. Don't let up on the latter till they cease to be partners in crime. [Doctor, suppose you tell them the plain truth. We will furnish you all the marked sample copies you want. Perhaps a word from you would have more weight than from A. I. R.—ED.]

THE ARGENTINE REPUBLIC, as reported by A. Michaut in *Apiculteur*, is a paradise for bee-keepers—no failures from drought or moisture (except once in 12 or 15 years grasshoppers allow a quarter crop); no foul brood or other disease; no moth; abundant harvest for three months in the vast alfalfa fields, and an average yield of 75 lbs. a colony at 3 cts. a pound, and 3½ lbs. wax at 20 cts. Perhaps Prof. Bruner will tell us about it.

SHEEP are good to keep down grass in an apiary, but they move hives on their stands more than cows or horses. [I am sure your experience is different from that of Vernou Burt and the rest of us. Whenever a horse is stung in the vicinity of our apiary, there is usually a fracas, and a lively one too. The last experience our Meg had at our home apiary was when she kicked over two hives and had a runaway generally. Say, doctor, do your sheep kick?—ED.]

REV. M. MAHIN, D. D., has observed closely, and never found bees working on strawberry-bloom worth mentioning till this year; but this year they worked as freely on it as on clover. He thinks an unusually damp and cool spring accounts for it. [Two or three years ago a few insisted that bees never work on

strawberries. Others stated just as emphatically that they did. The truth of the matter is, some years bees do visit strawberry-blossoms, and some years they do not.—ED.]

GLASS COVERS for hives seem to have gone out of use at Medina; but at least two correspondents of the *British B. J.* like them after four years' trial. [Glass covers! I hardly know to what you refer unless you mean two that we used during winter, sealed down over the brood-nest, and covered with packing for experimental purposes. The result of the experiment that season seemed to show that bees did better under absorbents than under sealed covers. The glass was simply a matter of convenience.—ED.]

C. P. DADANT says, in *American Bee Journal*, "Why two Unions? Can't we lay aside all disputes and come together? I belong to both, and am willing to help both; but how much stronger we should be if we stood together as one man!" Vous avez raison, mon cher ami. [Just so; and I believe that nine-tenths of both organizations are with friend Dadant. Amalgamation is not given up by any means; and I hope the new constitution, at the next convention in Buffalo, may be so worded as to suit the most fastidious.—ED.]

SWEET CLOVER, it has been said, will drive out flies if the stalks are hung up in a house. Big bunches are hung in our honey-room, and the flies seem to enjoy roosting on it. [I do not see how sweet clover could drive flies out of the house; but I can readily imagine how the flies would like to roost on it. But why have flies in the honey-room at all? Why not have screens and screen doors? If you send one of your women-folks out to the house properly screened (house screened, not the woman), I will warrant she will bat the flies to death in very short order. I judge your women-folks by ours, for they are sure death to flies.—ED.]

HONEY is quoted by the gallon, p. 547, in the *New York* quotations. Wouldn't it be just as well to have nothing but pounds? [When honey is quoted by the gallon it usually means southern honey, or an inferior quality, for such honey usually sells in the South by the gallon. I believe with you that it would be better if it could always be sold by the pound, for on that plan the producer is paid just as much for thick honey as for thin. Or, to look at it in another way, a premium is put upon thick honey—the only kind that ought to be put on the market.—ED.]

I DON'T WONDER, Ernest, that you have come to the conclusion that you want all your queens clipped. So far as looks are concerned, it need make but little difference. Cut the big wing on one side, leaving the little one intact, and you'll have to look pretty closely to see that a queen is clipped. [Yes, I am thoroughly converted to your way of looking at the matter. Say, doctor, is it wrong for one to change his mind? or should he stick and hang to his originally published opinion, right or wrong? There are some people I know, and editors too, who appear to feel that the latter policy is the better one.

As for myself, even if it is a little humiliating once in a while, I expect to right about face just as soon as I know that the other fellow is right and I wrong. I really do not mean to give anybody a rap on the head; but it would be better for bee culture if there were more who are willing to change front.—After reading the foregoing it sounded very "goody-goody"—a little too much so, perhaps. Can't help it. I believe in the doctrine of conversion from the error of one's ways.—ED.]

IS THE ABILITY to build comb inborn, or do the young bees learn it from the older ones? Kokevnikow, a Russian, secured a lot of young bees that could never have seen comb built, and they made a finished job of comb-building the first time trying.—*Bienen-Vater*. [Exactly. The young bees will build just as good combs as the older bees, just the same as young cats and dogs can swim as well as old cats and dogs. The puppy spaniel that I had swam just as well the first day I threw him into the water as he did on other days months afterward when he swam out into the lake for his own pleasure after blocks of wood had been thrown out for him to bring in.—ED.]

THICK TOP-BARS and  $\frac{1}{4}$ -inch bee-space do well as regards burr-combs; but brace-combs between top-bars are plentiful. [As a general rule, there are comparatively few burr-combs over thick top-bars; and there are practically none when the spaces between them are  $\frac{1}{4}$  inch. But our friends and patrons do not seem to like to have the top-bars quite as wide as you do, and accordingly there are occasionally burr-combs as well as brace-combs. There is a great difference in colonies. We have one at our out-yard that sprinkled the burr and brace combs in pretty thickly between the sets of extracting-supers, but they are as one in five hundred. It is the exception that proves the rule.—ED.]

ALMOST SURELY, Mr. Editor, you are right in thinking your home apiary overstocked with 300 colonies and nuclei; but a comparison with the out-yard doesn't prove it, for a like comparison of my home apiary with the north apiary would prove the first overstocked, although the two are about equal. A short distance often makes a big difference. [What you say is true. During the early part of the honey-flow I was called to hive a swarm half a mile from our home yard. I then observed that our neighbor's bees, some two or three colonies, while only half a mile away, had about three times as much honey per hive as colonies of equal strength in our large home apiary. This led me to believe that two things were true: First, that the home yard was overstocked; second, that bees do not usually fly much over half a mile in quest of stores; and it is only when they can not get honey within this range that they will go further. So long as there is a little to be had near home, so long are they content with that little. But, "all the samee," I do not believe it is wise to put out-aparies much nearer than two miles.—ED.]

## FIGHTING GLUCOSE IN CHICAGO.

The Plan Proposed on Pages 554, 555, Impracticable; the Legal Status of the Question.

BY HERMAN F. MOORE.

*Mr. Root*.—In regard to your plan to have Mr. W. A. Selser, of Philadelphia, make analyses of samples of suspected honey, it would not be best, as we could not use his evidence here in our courts without great expense in bringing him here to testify in person. No other mode of testimony would be satisfactory. The analyses must be made by some chemist near by, or in Chicago.

One thing to be remembered is, that there would be considerable expense connected with prosecuting these honey-mixers here in Chicago. It would be the best place on earth to make such a fight if made by one of our Beekeepers' Unions, because the best advertised; and any action here would be at once communicated to the whole world of bee-keepers in all lands.

We must remember who are our foes here in the outset. I inclose a clipping from a Chicago paper about the *Glucose Trust*. A new incorporation of the G. T. has just been made in New Jersey, with \$40,000,000 capital stock. These people are pushing their business here in Chicago, as I believe \$1,000,000 worth a year of their products is consumed and handled through this city in a year. They would undoubtedly fight us tooth and nail. Their first fight would be to furnish unlimited money to hire the best lawyers in Chicago to defend any one arrested for mixing honey with glucose, and to pay their fines if convicted. If the bee-keepers desire to push this matter it would be necessary to provide not less than \$1000 in money at the start to pay necessary expenses. It would be necessary to retain, to aid in the prosecution of offenders, one of the best lawyers in Chicago—one whose name would carry prestige in the courts and before the people. To retain such a lawyer a liberal fee would be necessary.

I should like to see a decisive move made against the works (glucose) of the enemy; but it should be done in the proper manner, and with a force commensurate with the wealth and fighting qualities of the said enemy, or it had best be left alone. I should be glad to hear from Mr. York, as he is here among them, and knows the conditions as well as or better than I.

I will say, for the benefit of those who know me personally, that, though I am a lawyer, I am not in a position to represent the Beekeepers' Union in such a prosecution, and have no thoughts of myself in the above remarks, though I should be glad to give them the benefit of any knowledge or experience I may have in the premises.

Chicago, Ill., Aug. 4.

[From your statement of the case it looks almost as if we were helpless. Although I am not a lawyer, nor the son of one, let us examine the matter a little from another point, for I feel as if we could not give it up. How will

this do? Employ Mr. Selser to analyze two dozen samples of extracted honey bought in the open market in Chicago. Suppose he finds one dozen of them to be adulterated. Would not this, coming from the Union, be sufficient evidence to induce the prosecuting attorney or the food commissioners of your State to bestir themselves a little, especially if the General Manager kept on dinging at them? Why, in the name or the good State of Illinois, is it necessary for the Union or any organization made up of private persons to defray the expense of prosecution that rightly belongs to the State? Ohio has an energetic food commissioner, and I have no doubt he had a constituency back of him who prodded him up to a sense of his duty; and those of us who live in this State *know* that he has made the food-adulterators fear and tremble. He even went so far that some of our "good people" actually began to protest, and they fairly begged him to "let up" on the poor persecuted mixers. The Union must not of itself assume the expense of prosecutions; but can we not give the Illinois State Food Commissioner, or whoever that functionary is, a little "waking up"?

It is too bad that the liquor element and the food-adulterators have got matters into such shape that it is hard to secure conviction; but the good people of our land must wake up, for the other side certainly are not asleep. Glucose and whisky, and all other enemies of the human stomach, must not triumph over right. —Ed.]

.....

### GLUCOSE, AGAIN.

BY R. M'KNIGHT.

I am surprised, Mr. Editor, that you too look upon glucose as vile stuff. You say, "The article that is ordinarily used for purposes of adulteration is hardly fit to put into the stomach of a pig, let alone that of a human being." I take it that the statement used in the above paragraph covers all articles "ordinarily used for the purposes of adulteration." In this you are certainly mistaken. Whisky, I believe, is usually adulterated with water; therefore water is unfit to put into the stomach of a pig. Coffee is usually adulterated with chickory, therefore chickory is vile stuff, unfit to be used by a human being. Mustard is adulterated with flour—your logic proves flour vile stuff. The sparkling diamond is chemically identical with the somber charcoal, so it will be in order for Cecil Rhodes and other diamond kings to denounce charcoal as vile stuff, and its producers scoundrels. Now that there is a large factory at Niagara Falls for manufacturing diamonds out of charcoal, all these adulterants are, I contend, legitimate articles of commerce, and their production is neither a fraud nor a sin. The fraud consists in mixing them with articles of a higher commercial value than themselves, and selling the mixed article for what it is not. The only proof you furnish that glucose is vile stuff is that it nauseated you once while

sampling honey mixed with it, and left you afflicted with "a horribly nasty taste" that clung to you for days. I have known people nauseated for days from sampling butter at a show-fair where all the butter was considered good. It is unfortunate that this article is believed to be largely used in adulterating honey in the United States. The practice is a fraud that ought to be stamped out, and I am pleased to learn that you are making progress in that direction. I believe that glucose, when properly refined, is not detrimental to health, and I am slow to believe that those who are engaged in its production are scoundrels. It is an extensive industry in your country. There is a line of steamboats running from Gladstone to this port that bring in tens of thousands of barrels of this "stuff" during the summer, and as many bags of grape sugar made from the same source. This is all through freight going to Britain and Europe. If it is used only as an adulterant the fraud must be widespread. One thing is certain—bee-keepers can not stop its production by calling it, and those engaged in producing it, ugly names. Perhaps your people have greater reason to feel sore over this matter. Honey adulteration is not practiced here to any appreciable extent. Out of several hundred samples analyzed by the Dominion chemist last year, only twelve were found to be adulterated.

Owen Sound, Can.

[In your first quotation you wholly misunderstood me. The quoted sentence standing by itself *might* admit of the interpretation that you have given it; but when placed in connection with the other sentences it will be seen to convey quite a different impression. "The article (namely, glucose) that is ordinarily used for purposes of adulteration is hardly fit to put into the stomach of a pig." I have reproduced the quotation, but have put in parenthesis the exact meaning I intended to convey. Your argument is all for naught.

You still fail to furnish one iota of proof to the effect that glucose is a legitimate article of commerce. If you will show me one legitimate use to which glucose is put, outside of its use as an adulterant, I will give you a chromo. It is possible that it is used in the manufacture of liquors; if so, it should be classed along with them.—ED.]

#### MARKETING HONEY.

The Problem of Candied Honey; the Policy of Replacing Candied Honey with Liquid, Condemned; Some Valuable Hints.

BY. J. A. BUCHANAN.

I believe I stated some time ago that I would have a short talk on this subject. It is one that is continually bobbing up. Articles of interest embracing many facts and some theory have been appearing in GLEANINGS for some time, especially the talks by Mr. R. C. Aikin. It is true, that bee-keepers who produce alfalfa, basswood, and other kinds

which soon granulate, will ever have trouble unless a way shall be discovered to prevent candying.

We have handled immense quantities of alfalfa honey, but have given it up on account of its ready disposition to candy. Mr. Aikin's suggestion to put up the honey in small cans of 1, 3, or 5 lb. sizes, and retail or wholesale in this way, letting it candy when it may, depending on the printed instructions as a means of information and education whereby the consumer may learn to liquefy his own honey, will do with only a very few people, as I tested this very plan some years ago.

Some four or five years ago I visited grocers in different towns and cities, on the hunt for bargains in honey that had been put up this way which had stuck on their hands, and, being candied, it was not wanted, but looked upon with suspicion by both grocer and buyers. I found in one store several hundred 3-lb. cans of candied white-clover honey, and bought the lot at 5 cts. per can, and the grocer was glad to get it out of the way. This honey was labeled with plain directions for restoring to the liquid form. It is surprising how few persons there are who will read instructions in the management or use of any article.

Some of the worst abuse I ever got in my life came from retailers and customers upon finding the honey I had sold to them had candied, or "gone back to sugar," as they put it, as well as firmly believed. We now handle only such grades of honey as will not candy, are or very slow to do so.

As to the matter of taking up all jars, cans, or glasses, and replacing with freshly liquefied stock, I can think of nothing more distasteful than such everlasting foolery and waste of time; not only so, but, worst of all, this re-liquefying will soon destroy both color and flavor. I have known several parties who once put their honey on the market in this way. I did so myself, but it's too puttering a business to keep up continuously.

In localities where the honey crop is not large, bee-keepers can find customers for all they produce, with little trouble, and at satisfactory prices; but the case is different where there are great quantities and no good home demand. In this case it appears to me it would be quite as well to wholesale and let it fall into the hands of those who make a business of handling honey by hunting up consumers. By the time this class pays freights, stands all losses, bears all expenses of traveling, taking orders, delivering, etc., he will find, these slow times, that his profits will all be taken at any ordinary bank, if not all, to defray expenses.

Just let every producer do his level best to sell in his home market all he produces, at the best price possible to obtain, going at the business with a determination to sell, and I am sure there will be no very large quantities find their way into the hands of city commission houses.

I have often bought bee-keepers' crops of honey and stepped into the towns right around them, and in a few days' work have doubled

my money on the purchase, while they all the time claimed there was no use to try any more to sell honey in "such places;" but I'll admit the fact that not all people are salesmen.

Although we sell large quantities of honey, both comb and extracted, each season, we never sell honey to dealers, but altogether to the consumer, giving them fresh honey, and so good that they will not keep it long enough to candy.

We put up no smaller packages than one dollar's worth, as it does not pay to deliver a less quantity at the close margin at which honey may be sold these times.

It has always seemed a mystery to me how it comes, that, in nearly every case, we are able to purchase honey of the same quality from commission merchants of the large cities at a less price than we can buy direct from the producer. Perhaps bee-keepers ship to cities in the hope of getting the best prices; but after waiting long and getting anxious for returns, they advise their dealers to close out at once to the best advantage, which is sure to be to any other person's advantage more than to that of the owner of the honey.

Now let every one who can find any thing like a fair home market go to work and supply this and keep it up, which plan will be found to give, in the outcome, the best and most permanent satisfaction as well as profit.

Holliday's Cove, W. Va.

[I believe I have already said—at all events I will say it now—that Mr. Buchanan has probably sold more honey, in a retail way, and has done more in the way of developing local markets, than any other bee-keeper in the United States. He annually produces large crops of honey, and not only sells his own, but sells for a good many others.

Mr. Buchanan's experience with regard to candied honey, and replacing the same with liquid, will probably not work satisfactorily with him; but Mr. Chalon Fowls, of Oberlin, O., has worked on this plan for years, and considers it profitable.

I was struck particularly with one paragraph where Mr. Buchanan says he has often bought bee-keepers' crops of honey, and sold it right around their homes, and doubled his money, while they, the bee-keepers, had all along claimed that there was no use of trying to sell honey in their markets. Granting that Mr. Buchanan is a natural salesman, and knows the art of selling, this does not explain how he should be able to double on his money, unless, at least, those bee-keepers who complain of their home markets have made no effort to develop them. Perhaps they are not read up—or at least have not read the series of valuable articles that have been running in GLEANINGS and the other bee-journals of late. Understand, I do not question Mr. B.'s right to double on his money. It is his privilege and right, if the other fellows won't post up and do something.

Mr. Buchanan calls attention to another significant fact; namely, that in nearly every case he has been able to buy honey of a given

quality from commission merchants in the large cities *cheaper* than he could buy the same honey direct from the *producer*. This is too true. It can be explained only on the ground that so much honey is sent to the cities that it gluts the markets; and the consequence is, the bee-keeper is glad to get any thing if he can only get *something*. Too often he is deceived by quotations that are above the market. Big promises for immediate returns at glittering figures allure him. Why will not bee-keepers learn to be careful? Nine-tenths of the producers know the art of *securing* honey; but I almost believe that nine-tenths of them do not know the art of *selling*. Why, we are to-day having the finest qualities of comb and extracted honey offered to us at prices that are ridiculously low. Sometimes we buy, and sometimes we do not. We very much dislike to be lugged into the "general swim" with those who are trying to buy closely, at the expense of the hard-working bee-keeper. It is too bad, but need not be if producers would not be so fast to lump their honey off in large lots for the sake of getting a "big pile" all in one lump.—ED.]

#### GOOD CROPS AND GOOD PRICES.

The Advantage of Selling around Home.

BY DAN WHITE.

I notice in last issue, July 15, comments about our large crop of honey. Some are afraid of a glut in the market, ruinous prices, etc. Now, if I can say a word of encouragement I will gladly do so. My this season's crop is about 7000 pounds, mostly extracted, and I expect to market every pound of it at fair prices. You know good help to work among bees is hard to find; consequently about four weeks' good hard labor by myself alone has secured this honey. I have no one to settle with for labor but myself. Now, is it good policy for me to sit down and wait for people to come and buy my honey, or put it in large packages and throw it on the market? I believe I can now well afford to do some hustling around, and sell this honey. Don't you see I shall do this myself? and when I get through, my expense account will not eat up a large share of my honey crop. I can now report one day's labor, 600 lbs. honey sold, nearly all for cash, and in the mean time I have found where I can place about 600 lbs. more just by driving around with the honey.

Let me give my price: 8 cts. per pound, in a small way; \$7.00 for 100 lbs. I have already filled and taken several orders for 100 lbs. in a family—some of them farmers too. Don't be afraid to go out among the farmers, and especially the laborers in villages and cities. I have told you before that four families out of five hardly know what honey is. Now, sir, we have lots of honey, and let's hunt these people out and tickle their palates with some good honey. We shall not only get rid of this crop, but we are making a market for future crops of honey.

I could hardly give the time to say what

little I have. I will report later how I get along. But I will add this much, and close: I have had a host of help around me picking, marketing, and looking after 8 acres of small fruit. When I get settled up, and expenses paid, I believe I shall take off my hat and give three cheers for the bees.

New London, O., July 20.

[Dan White is a "hustler;" and if you could see him once as I have, and imbibe a little of his enthusiasm—well, I think you could sell honey too. Our hustling friend asks a very pertinent question: Is it good policy for the bee-keeper to sit down and wait for people to come and buy his honey, or put it into large packages and throw it on the market? or shall he sell it himself around home, and get good prices? Just think of this a good long while, brother bee-keepers, and then ponder a moment on some of the things that Mr. Buchanan has said in the article just preceding.—E.D.]

#### DEVELOPING HOME MARKETS.

Putting out a Fine Article, and Having it Stand on its own Merits.

BY B. F. UNDERDONK.

*Mr. Root:*—I notice an uneasiness in the minds of some of the correspondents of the various bee-journals as to what they will do with the large crop of honey in view this year. I would say to all, *make your own market.*

In 1895 I commenced with three colonies, and got a surplus of 89 finished sections, retaining imperfect ones for my own use. As my duties call me to the city every day I do all my apiarian work before 7 A. M., and after 6 P. M., working as early as 4:30 and up to 10 P. M. The first case, a 12-lb. section one, I fixed up, using wider glass than usual,  $3\frac{3}{4}$  in., to make a good display, and carried it into the house, and said to my wife, "Show this to the grocer when he calls for orders."

She asked him, "Do you sell honey?"

"Well, we always have it, but there is little sale."

"Is it as fine as this?"

"My! isn't that nice? What we have looks as though the mice had gnawed it. If that is for sale I'll take it and see what can be done with it."

This was in October. He sold my entire surplus; and when that was exhausted he sold all of his old stock—an appetite was created. In 1896 my surplus of 312 lbs. was gone by January.

The other grocer with whom I also deal wouldn't touch it. "Never sold any comb honey." This summer I told him he ought to sell honey, to be up with his competitor. "Well, I'll think about it."

The first honey I took off June 22, and sent him a case with the message, "If you don't sell it I'll take it back." He has now his fourth dozen. The other man has it also on sale. I have taken off 385 sections to date. Of course, among them are some nice and

white, but only three-fourths full, hardly marketable (of course, all sections are thoroughly cleaned); and as we have a fish-peddler who sells fruits and vegetables as well, I said: "Here, you can surely sell honey."

"Oh! I don't know."

"Well, now, these you can have at 10 cents; sell them for 15 cents; or two for a quarter; these No. 1 are 13 cts.; fancy 15 cts., to the grocers."

This peddler's route covers a circuit of five miles from the village, and is run three days. He sold out his case (12 sections) each day, and had not enough to go round. He has engaged all my incomplete sections. He got 15 cts. each, and a nice profit, \$1.80.

In the spring a neighbor living a mile away came to me and asked me if I would instruct him in the care of bees, as he knew nothing about them, and had a chance to purchase eight colonies. I have informed him on all points, and he is a credit to my teaching, making a success.

Some of my friends expressed surprise at my willingness to encourage competition as they called it. I told them that a successful competitor would increase the field of demand; that honey would be introduced to hundreds of families who would not otherwise know of it; but that I felt it my duty to benefit my fellow-man, even though I might suffer loss.

Mountain View, N. J.

#### SECTION-PRESSES AND THE RIETSCHÉ PRESS, AGAIN.

The Comparative Merits of the Daisy, Hubbard, and the Rietsché Combined Machine Discussed.

BY F. L. THOMPSON.

Some time ago Alois Alphonsus, of Vienna, stated that foundation could be made as thin with the Rietsché press as with a mill. He is a professional bee-keeper of good standing. That was the basis of my "assumption" of the possibility of making eight L. sheets to the pound with the press. I did not entirely believe that statement, but thought he was a little mistaken; yet it strongly indicated that foundation could be made pretty thin, for surely they can turn out 11 feet to the pound, anyhow, in Europe, on the mills there in use. At any rate, that statement, and your experience of three L. sheets to the pound, seem utterly irreconcilable. Though I have never seen a Rietsché press, what I read about it makes me lingeringly suspect that your experience with it is not identical with that of foreign bee-keepers. Did you use the honey and alcohol lubricant? The press is frequently referred to in high terms by disinterested parties in a number of foreign bee-papers which I receive. I hope to learn before long just how thin the *improved* machine makes foundation. I think it would be well to find out all about this; for until then I, for one, and no doubt others, will feel uneasy, and be tempted to send our hard-earned dollars across the ocean for something to save money with.

Yes, I did think you were favoring the supply-dealer at the expense of the bee-keeper, but supposed it was because you were under the false impression that you were favoring both. One may be mistaken in this as in other ways—in fact, more readily, for the consideration of unconscious bias comes in.

So far I am not certain that I may not have got the worst of it; but now for the next round—look out! You say you have "carefully tested" every combined section-machine sent you. What does this mean? A machine *might* be carefully tested in twenty minutes, and a verdict given. But in the case of any machine depending partly for its speed on the way it is handled, a short test is no test at all, unless its defects are quite obvious. Otherwise no machine you test is on equal terms with the Daisy. Not less than five thousand sections should be put up, and ten thousand would be better. The operator must learn to finger it as an expert does a piano. This requires time, and lots of it; but I see no other way to do. Piano-fingering is exceedingly awkward work for a long time; but, when once learned, the motions required are as elegant and effective as they formerly seemed awkward and unnatural.

I have not tested the Daisy— not because I do not want to, but because I have not time at present, and have not a suitable lamp. But I will leave it to you whether there are not some things I can say about it, as well as the Hubbard, which I have not worked either. (I have used, besides the Rauchfuss, the Parker and the Clark machines, and a treadle press called the Beeson.) My objection to all separate machines is that, in folding, certain motions are gone through with that have to be done over again when the foundation is fastened. If you could combine the Daisy and the Hubbard, wouldn't you do it? But, this idea is "theoretical." Not so. The other day I made repeated experiments with lots of twenty sections each on my machine, some previously folded, and some not, to ascertain how much extra time the folding took when both operations were performed together. One lot, already folded, was supplied with top sheets at a rate which, if continued, would be 450 an hour. Another was folded and supplied with top sheets at the rate of 436 an hour—a very trifling difference which leaves the Hubbard out of sight, even at the rate of 500 in 15 minutes. In another case, in which both top sheets and bottom starters were used, one lot with and one without folding at the same time, each lot was done in 4½ minutes (or 266 an hour)—no difference at all. (By the way, what is the record of the Daisy in putting in both top sheets and bottom starters?) I may mention here that I made several trials of 20 sections each on the folding part alone, out of curiosity. The average was 20 in 65 seconds—a rate of 1000 in 54 minutes. An expert might equal the Hubbard. But, of course, there would be no object in folding separately. I mention this simply to show that no time is lost by the method of folding employed.

In fastening bottom starters only, in previously folded sections, I reached the rate of 490

an hour. Small starters appear to be handled a trifle easier than full sheets. When this rate, with my experience (at that time), in putting up only 5000 sections on this machine is compared with your rate of 500 an hour, and an experience of hundreds of thousands, probably, on the Daisy, I don't think there can be much doubt as to the conclusion to be drawn concerning the foundation-fastening portion of the Rauchfuss machine; and when you come to add the 15 minutes previously required to fold those 500 on the Hubbard, and then compare the total result with the fact that the combined machine adds less than *three* minutes to its separate record to accomplish the same result, it looks as though inexperience with the combined machine actually did better work than experience with the separate ones.

But I hear some one say, "Oh! if you are going to compare your *spurts* with the ordinary records of others." To this I calmly reply, Consider the piano again. A beginner of, say, 400 hours' practice may spurt all he pleases; but he can not run a scale, nor hop around among the sixty-fourth notes, nor execute a trill, at a quarter of the rate in which an expert does it, and the latter will carry on a conversation at the same time. In other words, when speed depends on strength the inexperienced may gain by spurring, but not when it depends on dexterity. Of this I became painfully aware when, in making the "spurts," my fingers boggled and hit the corner of the press more, it seemed, than they did before.

As to quality, I grant the excellence of the toggle-joint in saving power, but contend that sufficient power for the purpose can be saved in other ways. The Rauchfuss machine saves power in two ways; first, by a treadle, by means of which the same bodily exertion with the foot applies greater force than with the hand; second, by a lever in the machine itself. The power is at one end, the fulcrum at the other, and the pressure is applied about a third of the distance from the fulcrum to the power. If any person were inclined to criticize the resulting exertion required, he could do so without touching on the principles of the machine. It would only be necessary to lessen the distance from the fulcrum to the point of pressure. But I do not know that there would be any object in doing this. As it is, the exertion is trifling (on properly dovetailed sections), and, what is more to the purpose, the work is perfect, so I do not think the Hubbard would be preferred on account of superiority in results.

Passing to the quality of the work done in fastening foundation, I call your attention to Mr. Hutchinson's statement that he has met with better success in fastening flat-bottom foundation by pressure than with the heated-plate machines. I assume that, among the latter, he includes the Daisy; but he does not include the Rauchfuss, as he has not tried it. Sonnambulist, too, says this is his (or her) last year with the heated plate. Hence, without having used it I may infer there is some reason for thinking the work of the Daisy is not perfect; for, although neither of them

mentions it, other heated-plate machines are not common. Now, unless I am greatly mistaken, flat-bottom foundation was the kind chiefly or exclusively used when the Rauchfuss machine was being constructed and experimented with. At any rate, I know by my own experience with flat-bottom foundation that the machine will fasten it so it will tear sooner than peel off. This looks like superiority to the Daisy. The reason is, I suppose, the speed with which the foundation reaches the wood after leaving the heated plate. The construction of this machine is such that if, for a guess, the starter in the Daisy drops in  $\frac{30}{500}$  of a second, in the Rauchfuss it must drop in about  $\frac{1}{500}$  of a second. The heated wax has no time to begin cooling before it has gripped the fibers of the wood. By sliding the foot off the end of the treadle, not lifting it, the spring gets in its work like a flash, and meanwhile the fingers of *both* hands exert on the starter a downward pressure which reaches its maximum at just the proper instant, since, by practice, the action of the foot becomes automatic. This speed renders entirely unnecessary any surplus of melted wax, such as I have seen accumulated on a lamp used in the Daisy. A touch, and it is done, when the lamp is hot enough; and the hotter the better. Thus foundation is saved.

A mere inspection of the machine will convince any one that its work can not be inferior to that of the Daisy, for all the good points of the latter are retained; and, for the reasons mentioned, I don't think it much of an assumption to infer it is superior, even if I have not tried the Daisy.

I ought to add that I find it better, in folding sections with the Rauchfuss machine, to give a sudden *punch* to the treadle, instead of a simple pressure. By so doing it never fails to drive the locked corners as tight as they can possibly be, with but slight exertion.

If you are going to test the machine, I advise fastening the wire which connects the treadle with the lever to that one of the two holes in the treadle which is nearest the center. This allows the foot to slide off the end of the treadle when releasing it. It is only by so doing that the full play of the spring is obtained. Also be careful not to get too many fingers in the section. The forefinger and thumb of each hand are sufficient. Press the foundation only *down*, not in any other direction. The two forefingers should rest on the top edge of the foundation. When holding the section in position for folding, it is not necessary to bring the dovetails any nearer together than to bring them just inside the jaw. The machine does the rest, providing the upper and right-hand portions of the section are *pressed against the back of the machine*, not toward each other. This is one way in which the machine saves time. Those accustomed to the Daisy are very awkward with this machine at first.

Montrose, Colo., July 20.

[I am willing to admit that the Rietsche press may have achieved in Europe better results than we have been able to secure from

our press of the same make; but, taking every thing into consideration, your position is a little lame by reason of the fact that you have never tried the Rietsche yourself. But the fact is still significant that the manufacturer of the machine we had, at least, did not claim that it would make more than five and one-half sheets to the pound. Granted it could make eight on their improved machine, I do not see how it could be possible for it to compete with the foundation bought in the open market, at present prices, for the reason that I do not believe the average bee-keeper is skillful and expert enough to reach a speed that would warrant him in trying to turn out an inferior article at home, to say nothing of messing things up generally.

Granting all you say with regard to the difference between trained fingers and fingers new to the work, there still remains the fact that you have not tested, as you say, either the Daisy or the Hubbard machine. In order to form a correct estimate one should be reasonably familiar with both the combined Rauchfuss and the two machines that seem now about to enter the contest. As I have never tested the Rauchfuss I will not discuss the relative merits of the two classes of machines at this time, because a Rauchfuss is already on the way, and ere long I hope to be able to make a report on it. In the mean time, permit me to say that I am inclined to believe it is a good machine. Yes, I will go further and say it is possible it may do more rapid work than the two separate machines we have used. I hope it may. When it arrives I shall be interested in seeing it have a most thorough and careful test; and if it is all that you seem to think it is, we shall be very glad to enter into some sort of arrangement whereby we can supply it to our general trade. We Medinaites are always looking for something a little better than we already have; and when we find it we are glad to place it before our customers.—Ed.]

#### OCcurring THOUGHTS.

BY J. W. SOUTHWOOD.

The lateral moving of the self-spacing Hoffman brood-frames when hung on the new tin rabbets is so easily and quickly done, and the frames at the same time so nicely adjusted, that they are worthy of much merit as time-savers. Just think of moving all the frames from either side, and adjusting them at the same time, compared with the manipulations of the old-style frame.

Of course, it is more work for a busy and tired editor; but I say, give us footnotes. Often, when busy, I read them first, to see if I desire to read the article. They are full of thought, broad in remembrance of like things or sayings, yet condensed and right to the point. Continue to give us footnotes.

I think sometimes we bee-keepers are too hasty in coming to conclusions, and thus mistake the exceptional for the general habit, trait, or characteristic, then hasten to give the

public our mistakes. One or two observations or experiments are not enough.

I may be wrong, but sometimes I wonder if it would be possible to have some queens and comb of *Apis dorsata* shipped over to some Southern State, the queens clipped, and introduced into some Italian colonies, and the combs, containing drone and worker cells, inserted; and, when drones are produced, endeavor to mate with Italian queens.

I know we can not all arrange our articles as well as W. Z. Hutchinson and the editor; but we can exercise care and thought. We sometimes mention things that are not interesting. That able writer, in speaking of measuring combs which the bees spaced and built as they chose, said he measured some of the combs of his father's box hives in the barn some 27 years ago. It is of no interest to know whose hives the combs were in, nor whether they were box hives or gums, nor when it was, nor where they were. The points of interest are the thickness of the combs and the distance from center to center.

The basswood bloom was not as plentiful as usual, but was sufficient to give a good supply of nectar; but the extremely hot and dry weather brought out the bloom nearly all at the same time, and almost dried the bloom as soon as out; and if bees worked on it any it was early, as I was under small trees at different times and could neither see nor hear a bee at work. White clover is abundant. It did not yield well at first, but is yielding well now.

[*Apis dorsata* could not, I think, be crossed with *Apis mellifica*, another species.—E.D.]

#### NOTES BY THE WAY.

BY J. T. CALVERT.

After crossing the Rocky Mountains, so full of wonderful and enchanting scenes, their lofty peaks covered with perpetual snows, and where the pure water of the mountain streamlet, laughing and dancing on its way down over the rocks, ever increasing till it becomes a mighty stream, we come to the plains of Western Colorado, where, under the influence of irrigation, great transformations are taking place. Fruits in great abundance and variety are produced. It is estimated that there will be several hundred carloads shipped from Grand Junction this year. The honey industry is also flourishing here, and this year's crop is estimated at six carloads for shipment from this one station. This is produced from alfalfa, and is of excellent quality.

In our short stop of an hour here I hunted up The Abbey Hardy Co., commission dealers, who supply the larger portion of bee-keepers in this vicinity. They also supply fruit-men, and are large shippers of fruit and honey. From the number of young orchards which we passed, it would appear that only a beginning had been made in fruit-growing in this valley.

On arising the next morning we found our-

selves in the charming Utah Valley, still surrounded by the snow-clad hills. The neat and comfortable homes, surrounded with fruit and farm products in great abundance and variety, betokened the thrift of these people.

We stopped for two days in Salt Lake City. This is a charming city in many ways. The streets are all laid out very wide (110 feet), about twice as wide as ordinary streets. All the poles for telegraph, telephone, and electric-light wires, etc., are in the center of the street, and on either side of these the street-car tracks, leaving a very wide space for driving, and an unusually wide walk. In the gutter, between the walk and the street, on both sides of almost every street, is a beautiful stream of clear spring water from the mountains. This may be turned into the gardens by side runs across the walk, making irrigation very easy and convenient. All around the city are the snow-clad mountains rising several thousand feet. From Fort Douglas, just outside the city limits, on the foot-hills to the east, a splendid view of the city and valley beyond is had—Salt Lake itself spreading out on the western horizon 25 to 30 miles distant. The water of this lake is so heavy with salt that one can not sink in it, but will float with head and hands and feet all above water. I know this is so, for I tried it myself. The water is so very strong that one is in danger of strangling if he allows his head to get under water. No matter how weary you may be, you will find here that your feet are so light that it is difficult to get them under you again after you have allowed them to come to the surface.

While in Salt Lake I visited at the home of John H. Back, our agent handling bee-keepers' supplies at this point. From him I learned that there had been a heavy loss of bees in Utah the past winter, many having allowed their bees to starve for lack of attention. The prospect for a honey crop was good with those who had given their bees proper care and attention. The principal sources of honey here are alfalfa, and sweet clover, which grows in abundance in most of the waste places.

I was not fortunate enough to meet any other bee-keepers here, although I learned afterward that one or two had tried to find me, and failed.

The Christian Endeavorers from the East, journeying to the Golden Gate, spent Sunday here, and held what was called an inter-mountain rally. There were some 50 special trains, each bearing from 300 to 500 people, who stopped here for rest. We were royally entertained, and no doubt left behind us a lasting impression.

Leaving here early Monday morning we passed on through Ogden and across the great alkali plains of Utah and Nevada, reaching Reno on Tuesday morning. Here I spent a day visiting the bee-keepers who, in past years, had shipped us such nice alfalfa honey. I found here the prospects for a honey crop the poorest they have had in years. While they should have been taking their first and best honey from the first crop of alfalfa, the

bees were scarcely making a living, while the first crop of hay was being cut earlier than usual on account of two obnoxious weeds that were becoming a great pest, requiring the cutting of the alfalfa earlier to prevent the weeds going to seed.

I found that perhaps the most progressive bee-keeper in the vicinity of Reno was a woman, Mrs. Sherman. I spent two or three pleasant hours in her home hearing her tell her experience, which was usually one of trial, and dearly bought. I visited her shop, where she and her daughters make the necessary preparations, even to making their own foundation. She is so careful in the grading and packing of her honey that she has always been able to sell it at a good price, thus reaping the reward of her unremitting toil and careful management. I found two others of the principal bee-keepers — Mr. Ball and Mr. McCart—away from home. I hired a bicycle and went out into the country a few miles, and had a short visit with Mr. Cooper and Mr. A. C. Hash.

In this section they have rain during only two or three months in winter, and they depend upon irrigation for most of the beautiful vegetation and field crops of the valley, through which flows the Truckee River down to the arid plains, where what is left of it sinks out of sight.

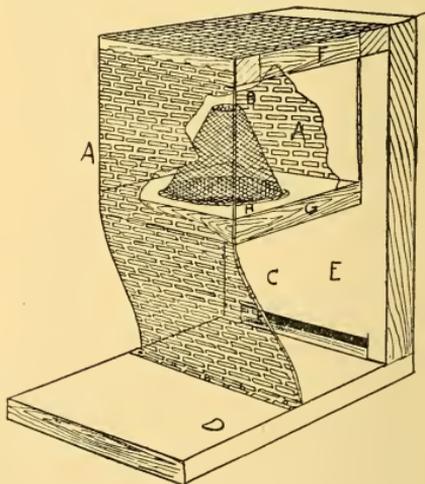

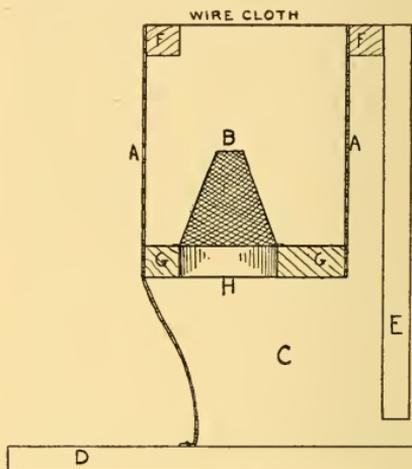

As I pass over these immense plains of barren waste, yielding nothing for mankind, and note what may be accomplished by the water stored up and distributed in sufficient quantities at the proper time, making the desert blossom as the rose, and produce all manner of fruits and vegetation for the blessing of man, and remember that, for most of this country, water falls during the year in sufficient quantities, if stored up and utilized at the right time, to make all this region productive, I think of Jesus' words to the woman at the well: "He that drinketh of the water that I shall give him shall never thirst, but they shall be in him a well of living water, springing up unto everlasting life." The fountains of God's grace are sufficient to bring joy and peace in abundance to all mankind. They only await the co-operation of man and the intelligent application of his truth to our lives—not in an avalanche once a year during the winter revival season, but the daily streams with gentle flow and subtle power, divided and subdivided till it reaches every act in the daily life of every living creature. If in the distribution of water through the irrigation-ditches any portion is omitted, the vegetation there soon withers and dies. So with any life that is not constantly supplied from the fountain of God's grace.

#### IMPROVEMENT IN DRONE AND QUEEN TRAPS.

BY ADRIAN GETAZ.

In using queen-traps I have often found them too slow in their work. What I mean by this is that, before entering the cones, the drones remain too long below, trying every

hole in the zinc before they go up. The same inconvenience is found with the queen at swarming-time. During the excitement the queen will run to and fro over the zinc, fail to find the cones before the swarm is all out, and finally go back into the brood-nest.

In trying to improve the trap I find that the best way is to use a piece of wire netting instead of a tin slide to cover the trap. The light attracts the drones and queens, and to a great extent the workers also, and they go up at once. In such a construction it is necessary to have the front of the upper compartment made with bee-zinc so as to permit the workers to go out. The accompanying figure shows the details.

Knoxville, Tenn.

[Your improvement on the Alley trap, I feel sure, is a good one. Quite by accident the artist has suggested in his drawing another

er improvement; namely, allowing a large amount of zinc surface just in front of the entrance, as at C. The ordinary Alley traps have too few perforations through which the bees pass back and forth into the hive, to allow of proper ventilation, and probably for next season, at least, we shall modify the trap somewhat on the line suggested in your letter, leaving at the same time a large amount of perforated-zinc surface so that, during the height of the honey-flow, the bees may not suffer from want of sufficient ventilation. If the entrance is too contracted, or at all obstructed by perforated zinc, the heat inside of the hive is apt to be such that the super will be deserted, and the bees will be clustered out in front; and those bees that cluster outside cluster over and about the entrance so as to make the opening much smaller, and thus at the same time considerably aggravate the difficulty.—ED.]

### THE NEW UNION.

A Movement on Foot to Kidnap it; a Note of Warning.

BY DR. A. B. MASON.

*Editor Gleanings:*—I've just read Mr. Herman F. Moore's article on page 554, in regard to the pure-food laws of Illinois, and it occurs to me that the new Union is being the means of getting some of our eyes open. Like you, I presume a goodly number of honey-producers, as well as others, have been thinking that the work of the U. S. B. K. U. would be in securing pure-food legislation; but Mr. Dandant's ideas were first-class; and he, being one of the Board of Directors of the Union, I thought we might soon hear that work had been begun by the Board along the lines he suggested; but here comes our old (or, rather, *young*) friend Mr. Moore, formerly of Ohio, but now an attorney in Chicago, and he gives us the *law* of Illinois on pure food, or, rather, the adulteration of pure food. It is as good a law as could be asked for, unless a pure-food commissioner would make it more valuable, and I doubt not we shall hear that the Board of Directors have begun work along the line proposed by the constitution, in looking after the adulterators of and dealers in adulterated honey.

Mr. Moore's article is very timely, and shows his interest in this work; and I hope it will be the means of starting the Union on its mission. I'm wondering if it would not be a good plan for General Manager Secor to get some one in each State in the Union to look up the law on this matter as Mr. Moore has so thoughtfully and kindly done. Perhaps some bee-keeping attorney in each State will follow Mr. Moore's example, and give us or the General Manager the law on the subject. There need be no great expense in learning just what each State has on this subject, and no very great expense in having such laws enforced, for they provide for their execution at the State's expense; but the Union can see to it that some one "starts the ball rolling."

It may be well to have some samples of suspected honey purchased and analyzed, as you suggest, and begin the good work right in "bad Chicago;" and with Mr. Moore, Dr. Peiro, Dr. Miller, Mr. York, and a goodly number of other members of the Union right on the ground, we may look for gratifying results being accomplished, and without making a very big demand on that \$3800 income of the Union, which Skylark, in one of his "flights," predicts will be "overleaped" this year.

While I think of it, Mr. Editor, isn't Skylark an active member of the Ananias family? No person by the name of *Skylark* has sent me "two dollars and fifty cents" for membership in the U. S. B. K. U. The man who sent in that "two dollars and fifty cents" has got a good straight honest name, and not a word about "Skylark"-ing in it. I might say that each bulldog that sits on the "coffers" that Skylark refers to has a collar around his neck with the name of the State he represents on it, and those bulldogs are so fed as to develop the most intense bulldog nature; and woe betide any non-union person who may attempt to interfere with the deposit each so faithfully guards.

I have not thought of your suggestions enough to say what will be the best course to pursue; but I am sure that our Board of Directors are abundantly qualified to handle the matter, and I hope they will *at once* proceed to business, and the Board may draw on my Illinois coffer to the full amount of any expense they may incur; and if there doesn't happen to be enough in that coffer I'll open up others to honor their drafts.

As I have said before, every honey-producer, every lover of honey, and every dealer in honey, ought to help on the good work by sending a dollar to General Manager Secor or the Secretary, and not be selfishly reaping the benefits of other people's investments. If only a small portion of such should respond to this suggestion I might have to enlarge those "coffers," and feed the "bulldogs" a little more heavily.

I'm sure Mr. Moore's article will cause a thrill of joy in every member and friend of the Union, and I know I shall work with renewed pleasure for the accomplishment of the objects for which it was organized, for their accomplishment seems nearer in sight.

While having some business correspondence recently with A. B. Williams & Co., of Cleveland, O., dealers in honey, I referred to our Union and its objects, and stated, as above, who ought to belong to it. The next mail brought a request for information in regard to the Union; and the next day, after getting the information, their dollar for membership in the Union lay safely in my Ohio "coffer."

Nearly every day I am receiving a membership fee, and some days several. On the 18th of last May I received 24 names and \$24 from Mr. J. Webster Johnson, of Arizona, Secretary of the Salt River Valley Bee-keepers' Association, making 24 members; and another day I received 7 names and \$7.00 from J. P. West, of Minnesota, making all members of the Union; and I presume General Manager Secor

is being made equally happy in receiving names and dollars for the Union.

Congratulations and good wishes for the "kid," and offers of more money if needed, frequently accompany remittances. One bee-keeper, in sending his membership fee, says, "I'm a poor man; but if you want more money, call on me and I'll help all I can;" and others come with offers of more money if needed. If each one whose interest is involved in the success of the Union's work would send his name and dollar there would be no lack of funds.

I got a letter from a Canadian this week that kind o' riles me. He says: "I am pleased to see that you are making every effort to have a grand convention at Buffalo, N. Y. From what I can judge you will succeed. I have every reason to believe that there will be a good attendance of Canadians as well."

Here's what makes me "bile." "I may give you a hint—I expect to see as many Canadian as United States bee-keepers at the convention; and if there are, we may vote it a Canadian instead of a United States organization. Ha, ha!"

Now, Mr. Editor, isn't that "galling"? We've licked "Johnny Bull" twice, and now some of his offspring propose to drop in on us unawares at Buffalo, and "lick" us out of our boots on our own soil. "To arms! to arms!" Turn out, Yankee bee-keepers, and meet the enemy (?) and they'll be ours. Stir up your readers Mr. Editor, let us not be vanquished.

I've already written to the *Bee-keepers' Review* to give the note of warning, and shall write the editor of the *American Bee Journal* in the same strain, and would also send to the *American Bee-keeper*, the *Progressive Bee-keeper*, the *Busy Bee*, and the *Southland Queen*, were it not too late. Oh that I had received this hint before! The Canucks have imbibed some of our Yankee vim, and they may give us a good "tussle;" but let us not get left. Transportation is cheap, so let every one who can be on hand with arms and rations for a three-days' tussle. It would be too bad to let the Canadians kidnap our healthy growing "kid."

I shall take Mrs. M. with me to take care of me, and no one but a coward will attack a woman, and the Canadians are not cowards; so I am safe; but woe betide those without women to hide behind.

[No, no; we can't afford to let the Canadians kidnap our growing kid. My better half expects to be present. Yes, bring on the women. We may need their help.—Ed.]

#### BRODBECK'S "ONE THING LACKING" IN THE CONSTITUTION OF THE NEW UNION.

[After the above was in type we received the following additional matter.—Ed.]

I have just received a letter from Mr. Geo. W. Brodbeck, of Los Angeles, Cal., in which he says, "If time and circumstances permit I may forward a few suggestions in connection with a revision of the constitution of the U. S. B. K. U. The one mistake made at Lincoln

was in not making the U. S. B. K. U. a distinctive national organization; for if this had taken place the old Union would have been forced to surrender and you would have enlisted the interest of several thousand bee-keepers in the United States who now stand aloof. It is an evident fact, that two like organizations can not exist; and, if I am not mistaken, unless there is a compromise between the two the B. K. U. will revise their work and follow in the line of the U. S., and the result then will be a mere question of time. I should like to see *one* good organization do all the work required; and, as a member of both, I am willing to aid, as far as lies in my power, to accomplish this purpose.

"Controversies, as a rule, act as a wedge when opposite results are desired; but a settled purpose to compromise differences ends in brotherly love. I have no desire, doctor, to pose as a critic, as my sole interest is in seeing one grand union of bee-keepers in the United States."

I don't remember that I have anywhere referred to the spirit that actuated the formation of the constitution of the U. S. B. K. U.; but I want to say that a desire to serve the interests of honey producers, consumers, and dealers, was at the bottom of the whole matter; no selfish interest happened into it. You know, and so does every other reader of your journal who has read my articles, and what I have said at conventions, that I was a firm opponent to the amalgamation of the N. B. K. U. and the N. A. B. K. A. *unless* it could be accomplished without in the least interfering with the efficient work of the National Bee-keepers' Union." I have repeated this many times, and I *know* that you and those engaged in trying to bring about the union of the two, and enlarging the scope of their usefulness to the pursuit, thought just as I did about the matter.

After a good deal of correspondence by the members of the Amalgamation Committee, and all hope of accomplishing any thing had fled, I drafted what, after some alterations, is now the Constitution of the U. S. B. K. U. My original draft was submitted to several leading bee-keepers for criticism; and after all this was done you were so well pleased with it that, without consulting any one, you had it put in type and printed, and sent me fifty copies to do with as I saw fit, and I sent about twenty of them to our best-known bee-keepers for criticism and suggestions, such as Mr. Newman, Prof. Cook, Mr. Brodbeck, Mr. Secor, Dr. Miller, Mr. Hutchinson, Hon. R. L. Taylor, R. F. Holtermann, Mr. Doolittle, Mr. Elwood, and Mr. Manum. Nearly all replied. Most were satisfied with it as it was. Mr. Newman and Prof. Cook each made one suggestion, if I remember correctly.

The whole matter, with all the suggestions offered, was submitted to the Lincoln convention, and by it referred to a committee of three, all members of the National Bee-keepers' Union, to be put in shape for its adoption or rejection by the convention. The committee met in Dr. Miller's room at the hotel (although he was not a member of the com-

mittee and went over the whole matter carefully. They then invited about fifteen other members of the convention, among whom, if my memory serves me, were Dr. Miller, Rev. E. T. Abbott; L. D. Stilson and E. Whitcomb, of Nebraska; E. Kretchmer and Hon. E. Secor, of Iowa, and A. I. Root; and I believe all sanctioned the work of the committee. I may say here that most of those invited to meet the committee were then, and are now members of the National Bee-keepers' Union, three of them members of its Advisory Board.

No material change of the constitution as it went to the hands of the committee was made by them, and none by those invited to meet with the committee. It was then submitted to the convention, and gone over and discussed and adopted section by section, only two changes being made, I believe.

Being opposed to amalgamation, except as above indicated, I took *special pains*, in drafting a constitution, to have every thing so shaped as to favor and forward the interest of the National Union, going so far as to make the officers of the old Union the Board of Directors of the U. S. B. K. U., and leaving the funds, as before, entirely in the hands of and at the disposal of those officers. I *know* that the aim was to make it as nearly in intent as possible to the old Union's constitution, some going so far as to suggest that it be called "National," with the expectation that the old Union would adopt the new constitution.

In the light of these facts, what more could have been done than was done? Of course, we don't know what Mr. Brodbeck means by "the one mistake made at Lincoln," nor how it could have been made more "distinctly national." Unlike Mr. Brodbeck, there are those who think the constitution is "incomplete, and full of incongruities." I myself must admit that it is incomplete, but that is owing to the effort made to make it as nearly as possible in line with the old constitution.

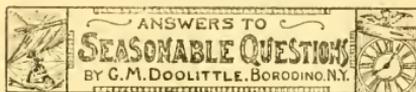

Perhaps "the B. K. U. will revise its work and follow in the line of the U. S." Some of us, member of the old Union, tried to have the "work revised," but failed; and the result was the organizing of the U. S. B. K. U. If the N. B. K. U. "follows in the line of the U. S.," I believe it will be following a vigorous young leader.

Why didn't Mr. Brodbeck tell us how to avoid making the Lincoln mistake? Perhaps he'll tell us how to correct it at Buffalo. Those interested in the success of the U. S. B. K. U., like Mr. Brodbeck, "would like to see one good organization," and are "willing to aid as far as lies in their power to accomplish this purpose," and *have* not and *will* not entertain any other feeling than "brotherly love," for their sole purpose is to have "one grand union of bee-keepers in the United States," and they propose to work in that direction till that desire is accomplished.

It is proposed by several to propose changes to the constitution at Buffalo, so as to make it as complete as possible; but all proposed changes will have to be submitted to every member for their adoption or rejection, and

this can not be done at Buffalo. From my correspondence I gather that the feeling is general that the coming convention is to be a large and good one, members in California, Arkansas, Tennessee, South Carolina, Rhode Island, Massachusetts, and Vermont, and many of the States between these, signifying their intention of being present.

Sta. B, Toledo, O., Aug. 6.

#### FEEDING BACK EXTRACTED HONEY.

*Question.*—I have read somewhere that, if I were to run an apiary for extracted honey, during the harvest of white honey, and feed the same back to the bees to put into sections, said extracted honey would sell in the section form for enough more to give me a big profit. Is this a fact? If so, how and when should extracted honey be fed back in order to procure comb honey?

*Answer.*—The feeding of extracted honey in order that comb honey may be obtained is something that has been tried by very many of our best apiarists, and still remains an unsolved problem with some of those who have tried it. Some have reported success and others a failure; but, if I am correct, those who consider the thing a failure far outnumber those who consider it a success. From my experience in the matter, I should say if any one must feed extracted honey to his bees in order that comb honey may be produced, it should be fed in the spring, in order to hasten brood-rearing, thus securing multitudes of bees in time for the honey harvest; then, by putting on the sections at the right time, a large crop of comb honey may be secured, if the flowers do not fail to bloom or yield honey. My experience has also led me to think that it is better to secure the honey in the sections in the first place, rather than have it stored in combs, and then thrown out with the extractor that we and the bees may go through with much labor and stickiness to secure the same thing which we might have secured without all this trouble. The practice of feeding back is on the principle of producing two crops to get one, and no one will argue that such a course would pay in the long run. Even under the most favorable circumstances, to finish nearly completed combs of honey, I can not make it pay if I count my time as any thing. At the close of certain seasons, when I would have a large number of unfinished sections, many of which were so nearly finished that a few ounces of honey would apparently finish them, it seemed that it might pay to feed a little extracted honey to finish such; but after a careful trial of the matter, covering a period of ten or more years, I finally gave it up as a bad job, and have not fed back a pound of honey during the past six years. If any one

should wish to satisfy himself that feeding back will not pay, he can get the best results by feeding the extracted honey right at the close of the early white-honey harvest, so that the bees are kept active. It is thought best by some to take away all combs except those which have brood in them, when preparing the colony for feeding back; but if all combs are filled with sealed honey, except that which the brood occupies, there is no advantage in taking away the combs, that I can see. The extracted honey should be thinned to a consistency of raw nectar, by adding the necessary amount of warm water, thinning only the amount needed for one feeding at a time; for if the thinned honey is allowed to stand long in warm weather, it is quite liable to sour and spoil.

Then there is another item against feeding back, which is that, from some reason or other, this fed-back honey is far more likely to candy or become hard in the comb than is that put in the comb at the time it is gathered from the field. When first taken from the hive it looks very nice and attractive; but when cool weather comes on in the fall it assumes a dull, unattractive appearance, thus showing that the honey has hardened in the cells; while comb honey produced in the ordinary way is still liquid, and will keep so for from one to three months after the fed-back article has become almost unusable.

#### COMBS OF HONEY FOR NEXT SEASON.

*Question.*—I have on my hives about 200 combs, very full of honey, which I wish to use for next year's increase. I am at a loss to know what to do, so ask if it would be advisable to throw the honey out with the extractor and use the empty combs, or would it be best to use the full combs of honey? I expect to make my increase by natural swarming.

*Answer.*—If extracted honey brings a good price in your market, and the honey in the 200 combs is of good quality, then my advice would be to extract the honey and sell it; for the old saying, "A bird in hand is worth two in the bush," is generally correct. If, on the other hand, extracted honey drags heavily, at a price hardly above the cost of production, or the honey in the combs is of a quality not fit for market, then I would store the combs of honey away till spring (allowing the bees to protect them till there was no danger of damage from the larvæ of the wax moth), when I would use these combs for building up colonies in the spring, by exchanging them with the colonies for combs that they might have which were empty, or nearly so. In this way you will get this honey converted into brood, which brood, when hatched into bees, will store for you large quantities of honey. If the colonies in the spring had no need for this honey, then I would use the combs of honey something as you propose, hiving new swarms on them. If the combs are only from one-third to one-half full of honey, then you may secure the best results by hiving your swarms on the full number of frames and putting the sections on at the time of hiving. But if completely full from bottom to top, it will be bet-

ter to use only from four to six combs to the hive when hiving the swarms; for, if given a full hive of full combs of honey, the bees may not carry much of the honey to the sections, as they generally will do with the whole where only a few are used. If the bees do not immediately start to carrying the honey from these full combs, the result will be little or no honey in the sections, and little brood and few bees in the hive in the fall. But should the honey in the 200 combs be of inferior quality or of dark color, or both, then the only thing to do with it is to extract, or use it for spring feeding; for if such inferior honey is given at swarming time, more or less of it will find its way into the sections, thus injuring the sale of the honey, and giving yourself a bad reputation.

#### COMMISSION HOUSES; THE ADVANTAGE OF CO-OPERATION.

The clipping inclosed is from the *Denver Field and Farm*. It does not speak directly upon the subject of bees, but I think it would be a good thing for bee-keepers to take example, as they have battles to fight in marketing their produce, similar to those of the farmer.

O. W. STEWART.

Las Cruces, N. M., July 26.

#### CO-OPERATIVE MARKETING OF CROPS.

When a crop is produced, but half of the battle against all the evils of trade is won; and unless the farmer finds a good market his labor is lost, and the complaint is made that the farm does not pay. There are many leak-holes between the harvest and the market, by which the profits escape through carelessness; but the most important point, requiring constant vigilance, is the fluctuating scale of supply and demand. Many times the western farmer and stock-raiser loses his entire shipment of potatoes or sheep, and frequently receives a bill for freight, with the stereotyped "please remit" stamped upon the paper.

There is no safety in relying upon the middle-men or agents of commission houses, because they give no guarantee of returns except such as the market assures on day of sale. The local merchants are not always justified in paying the value of produce, even in goods, for the reasons that they have not the capital to invest nor facilities for watching the market. Direct shipments can not be made to the market centers except by train or carload lots, and then experienced dealers must accompany the produce in order to realize the full benefits of all that the market returns. Individual marketing has always proven disastrous to the general farmer because of lack of business tact and the small lots of produce he has to offer.

The only solution of the question of realizing all there is in the products of the farm lies in the proper practice of co-operative marketing. The Utah Mormons have constructed irrigation-ditches, built up over three hundred towns, and conquered vast areas of desert by co-operative exertions, fully demonstrating the fact that the principle is correct. In citing these facts Joel Shoemaker asks: Why not adopt the methods used in selling as well as in growing produce? Twenty farmers could band together and practically control the community. Five of the best qualified men acting as a board of directors could employ one of their own number as a manager, and

transact the business with profit to the entire community.

This plan has worked a admirably and profitably in several instances under our personal observation, and the efforts of those enterprising fruit-growers at Montrose, Delta, and Grand Junction, in organizing local market associations, seems a very commendable movement. If it does not succeed as fully as some may hope for the first season or so it is a step in the right direction, and must eventually lead to a better condition all along the line. There is much to be learned in this as in other things; and after all we of the new West need a good deal of schooling in most of our undertakings.

#### A PROTEST; APIS DORSATA.

*Mr. Root*.—I can heartily indorse your views regarding the importing of *Apis dorsata*, page 488, and hereby enter my protest against the use of public funds for its importation. If they are of any great value it is surely a "good" personal investment for some of their advocates. From what reliable people in their native home say of them they are too much like wild geese to be of any value to bee-keepers in this country; but, instead, I think they would prove a curse, even if they could withstand our climates, which I very much doubt. I am quite sure that we already have too many varieties of bees in this country, for our own good, and surely more "names" than "varieties." Every thing considered in the make-up of the little bee, I don't believe there is a bee on the face of the earth to-day that is superior to the pure and simple three-banded Italians, and their equals are very scarce, judging from a "personal" standpoint, and information gleaned throughout the United States.

I have said before that I have had experience that I have never seen in print, in the early mating of a queen and a vast number of queen-cells on one comb; and last week I found something that seems as unusual to me, and I have never heard of the like, nor seen it in print.

#### WORKERS REARED IN WORKER-CELLS.

When I am extracting I make it a rule, after taking the combs from the extractor, to take my old uncapping-knife and shave the heads off from all drones found in the upper stories (I use no queen-excluders); and in doing this I found one comb full of what appeared to be drones, but noticed that the caps were not quite so prominent as usual; and when I severed the caps I found, instead of drones, perfect workers nearly ready to hatch; notwithstanding the cells were regular old-style and full-sized drone-cells, the little fellows really looked lost in them. Have you or any of your readers ever had an experience of this kind? It seems to me that it proves one thing positively; and that is, that the queen governs the egg-production by her own free will, and that the shape and size of the cell have nothing to do with it, as has been claimed by some writers in the past.

I am of the opinion that our basswood-honey flow is going to be very light here this season, as it is nearly all open now, and bees are not doing much, I think on account of the extremely hot weather for the past week.

Hillsboro, Wis., July 12. ELLIAS FOX.

#### HONEY-FLOW NOT EXTRAORDINARY IN WISCONSIN.

In answer to Dr. Miller, page 477, and Harry Lathrop, page 528, I will say that Northern Wisconsin will not glut the market unless on fall blossoms. Bees are in about the condition they were May 20, except excessive swarming since July 8. R. turned last night from an investigating-trip in the direction my bees all want to go, and have 50 colonies, new swarms, ready to start at sundown for an out-apiary 24 miles north of Chippewa Falls, Wis.

I find here willow-herb, goldenrod, frost-flowers, etc., covering the ground for miles where the forest-fires burned in 1895 and '96.

E. A. CLEAVES.

Eagle Point, Wis., July 20.

#### WHAT IS THE MATTER WITH THE WHITE CLOVER THIS YEAR?

My bees seem to be working very busily this season, but I don't know what they work on. I haven't seen a bee on a white-clover blossom this season. We have no timber within a mile, and not much within three miles, except a few artificial groves of cottonwood, maple, and willow. There is plenty of white clover.

SAMUEL CLOUGH.

Ellartton, Ia.

[This report seems to be an exception to the general run. All the rest say that the clover this year is all right.—ED.]

#### GRANULATION OF ALFALFA.

I am much interested in the discussion as to alfalfa honey granulating. My experience has been that it does not granulate here unless it be in the brood-chamber. I have kept alfalfa honey in 1-lb. sections for a year, and no signs of granulation; but last spring I found it badly granulated in hive (stores that bees had carried over winter).

We are just in the midst of our alfalfa honey-flow. The first crop of alfalfa did not produce much honey; but it is coming in very fast now, and I am afraid my bees will get the swarming-fever. The bees here are all run for comb honey — no extracting yet. I think the home market will take care of the surplus.

Alma, Neb., July 21.

T. L. PORTER.

There is an abundance of white clover here, and we are having a slow but steady and lasting flow. From 7 hives and a nucleus with which I began operations this spring, I have taken 238 lbs. of marketable honey in sections, with about 50 lbs. more ready to come off, and no diminution of the flow as yet.

Ben Avon, Pa., July 9.

H. P. JOSLIN.

I have been worked up to the highest notch myself, working every day at the railroad shop, and working with the bees nights and mornings. I have taken already 1400 sections of white-clover honey from 12 hives, and more to come.

W. L. RICHMOND.

Lexington, Ky., July 11.

RED and Alfaretta halted their ponies near the corral; and while Gimp cared for them they approached the house. The door was a trifle ajar. Fred knocked. There was a stir of chairs within, and hastening steps. The door opened, and Mrs. Buell's troubled face appeared.

"Fred Anderson!" she exclaimed, her face aglow. "Fred Anderson! Fred Anderson! Oh! where is my girl, my Alfaretta?"

"Right here, Mrs. Buell; allow me to introduce her;" and Alfaretta stepped within the house.

"Dear, dear mamma!"

"Dear child!" and mother and daughter were clasped in a long embrace. "My own Alfaretta again, and still not my own, not my own."

"Why, yes, dear mamma. Why do you say so? your own, and well again; and papa—where is dear papa?"

Fred caught Mrs. Buell's eye, and made an energetic dumb motion to her to keep quiet. She appeared much surprised, and abruptly asked, "Where is Dr. Hayden?"

Fred explained the doctor's queer departure, and took occasion to whisper to her, while from the veranda she was showing him where to find Prof. Buell, to say nothing about Alfaretta's parentage.

Fred hastened toward the levee where the professor was at work; but he had not gone far when he met his old friend.

"Fred Anderson, as I live," shouted he. "I had a strong feeling that something good was going to happen, and I hastened to the house. Dr. Hayden, of course, is with you and Alfaretta?"

"Alfaretta is at the house, and sane," said Fred.

"Sane? sane?" repeated Prof. Buell. "Yes, it is possible, and true if you say so, Fred; let us hasten. But, about Dr. Hayden—where is he?"

Then Fred explained to him the sudden departure in the night, and the motive.

"Sure, sure," replied Prof. Buell; "the same self-sacrificing man I knew years ago. I should have been so glad to meet him again. But I believe I shall tell Alfaretta all about her parentage."

"No, I would not," said Fred; "it is the doctor's request that you should not. It

might cause much pain to Alfaretta, with no good result."

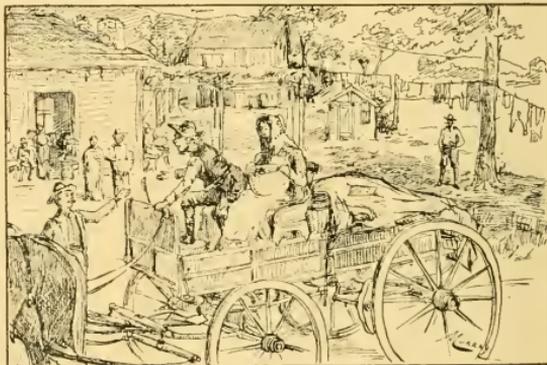

The professor's greeting was less effusive than Mrs. Buell's, but not the less hearty and loving.

"Dear Alfaretta! and yourself again! How great the blessings showered upon us! In this hour of our joy let us remember the Giver of these blessings, the healer of the sick, the one who brings great joy in the place of trouble."

The afternoon and evening were hardly long enough for the rehearsal of the experiences of the past year. Prof. Buell said he would have continued his search for Alfaretta again; but upon his return home he found a letter from Dr. Hayden, saying that Alfaretta would be cared for and returned in due time. This led him to await further developments, and now the sequel showed that Alfaretta's hejira the year before was a providential occurrence. The earthquake was a theme of constant recurrence in conversation, and Fred now learned of its extent. Sacramento had been thoroughly shaken, and the town of Williams had been so severely shaken that several houses were demolished. It was the most severe earthquake felt for years on the Pacific coast.

That evening Fred presented to the parents his claims for the hand of Alfaretta.

"It seems," said Mrs. Buell, "that your lives have run together ever since Alfaretta fished you from the river; and, Fred, as you have been instrumental in bringing her to us

well again, we shall let you two decide your own destiny."

"That is what you meant, mamma," said Alfaretta, "when you said I was not your own."

"I suppose so," said Mrs. Buell, evasively; "you know I was so overjoyed, Alfaretta, that I hardly knew what to say. Don't refer to my foolish words again, dear."

The next day Fred desired to visit the Ghering ranch, and Gimp was impatient to see his mother "an' the kids," so the party that rowed up the river consisted of the whole Buell family.

At the Ghering ranch there was great rejoicing again. Fred could hardly believe that Mrs. Ghering was formerly Mrs. Dawson, so great had been the change. He made particular inquiries for Matt Hogan; and while they were talking about him, who should appear

"Me ould friend, it's a heaven-sint idea," said Matt; "and is it Alfaretta that would make yer home comfortable loike for yees?"

It happened that day, that, after Mr. Ghering had shown all of the improvements he had made upon his ranch, the Dawson ranch was discussed.

"Wall, I 'spose the boys might work it arter a while," said Mrs. Ghering; "but perhaps it's better to sell it than to see it go to rack. But, Fred Anderson, it ain't every one I'd sell to; but seein' it's you that'll occupy it I'll sell, an' trust to suthin' to turn up fur the boys. They seem ter like fishin' better'n ranchin', any way."

but that worthy himself, driving a mule team to a farm wagon, and a comely Irish maid by his side?

Biddy Maloney had been caring for an aged father for many years. She had been a faithful daughter; and when her charge was released by death she hastened to join her lover here in California, and was proving as exemplary a wife as she had been a daughter. Matt had improved his neat ranch, a few miles from the river, and his main source of revenue was from a well-kept apiary.

"It is meself that can projuce the foine honey, Fred. I'd loike yees to settle down here now, and become a compaterter."

"Well, Matt, what do you think of the plan of my buying the Dawson location?"

"You know, Mrs. Ghering," said Fred, "that I will help your boys all I can, and shall want Gimp right along. We will rejuvenate the old place."

"That's jest my idea," said Mrs. Ghering, and the bargain was closed.

Fred was very happy for a few weeks in setting things to rights on the old Dawson place; and one of the first improvements was the purchase of a dozen colonies of bees of Matt Hogan, as a start for a large apiary.

"Sure," said Matt, "it will be a pleasure to have a neighbor baa-kaaper to talk to."

"Yes, Matt, there's nothing like being fraternal; and now if we had some of those Crystal Mountain queens I have told you about, what wonders we could accomplish!"

But," said Fred, sadly, "not even this place will ever equal the bee-keeping paradise that was in the beautiful valley."

There was a quiet wedding at the Buell residence one day; and, after a feast of good things, a boat gaily decked with flowers and streamers carried the bride and groom to their new home. A few weeks after the marriage a letter arrived, addressed to Alfaretta. It was postmarked "City of Mexico;" and upon opening it there was found a card inscribed, "Wedding-present from Uncle Ralph." With the card was a draft for \$5000.

"Dear Uncle Ralph!" said Alfaretta; "and what a generous gift! and what a strange man! I never could really understand him."

Fred thought that he might enlighten her; but, no—the secret of her parentage must be kept.

Fred devoted much of his ranch to fruit; and between that and the increase of his apiary he gave employment to several men. Gimp Dawson became so expert with the bees that he was given entire charge of the apiary during a portion of the year. The little church not far away called the people together every Sunday. Fred and Alfaretta became prominent factors again in the exercises, and were always at their posts of duty. Mr. Buell continued to minister to the spiritual needs of the people, and the little church was known as the "Goodwill Union Church."

Fred Anderson, in all of his past losses and disappointments, looked beyond the clouds to the silver lining beyond; and now when the clouds had rolled away, and he was living in the sunshine of prosperity and a happy home he did not forget the source whence all blessings come; and, having a fellow-sympathy for those in trouble, he ever held out the helping hand to them. The home that was now builded here was in marked contrast to the former unhappy Dawson home.

As the seasons progress, there is the seed time and harvest; there is the gathering of the fruit and the grain and the honey; and so, too, in progress of time, there is a wail of an infant beneath the roof.

Mrs. Ghering comes down to congratulate the happy parents. "I s'pose, Mr. Anderson," said she, "that's what you meant when you said you'd rejuvenitate the old place; an' what'r ye goin' to name the boy?"

"Ralph Hayden Anderson," said Alfaretta. "What a purty name, to be sure!" replied Mrs. Ghering; "may long life and joy rest on all of you."

The tourist passing up the river never fails to notice the neat rose-covered cottage and its well-kept grounds. The Anderson place is one of the beauty spots of the Upper Sacramento; and should he pass in the evening, a child may be seen tumbling on the lawn, while on the vine-covered veranda the happy parents, with guitar and voice, wake the echoes across the river with many familiar songs.

When about to close their evening exercise Fred will commence to thrum a well-known prelude. Alfaretta smiles toward him, and with both sad and pleasant memories of the past she sings that old song:

The night is stormy and dark,  
My lover is on the sea;  
Let me to the night winds hark,  
And hear what they say to me.

THE END.

FROM the best information I can get, gleaned from a good many letters, basswood has been generally a failure throughout the country, although in some sections it has been unusually good. A wet cool spring, very favorable for clover and grasses, was "a little too much of a good thing" for basswoods.

I WOULD call special attention to a valuable article by J. A. Buchanan, in another column. He has given us a little food for thought. It should not be true that honey can be bought at a commission house cheaper than it can be from the producer; neither ought it to be true that many bee-keepers make no effort to develop their own home market.

IN our last issue I confessed that I had changed my mind on the subject of clipping queens' wings. Mr. E. U. Parshall, of Cooperstown, N. Y., the old tramping-ground of J. Fenimore Cooper, writes: "I think you will enjoy bees better since you changed your mind. I could not keep mine where I do did I not clip my queens."

Mr. Parshall also writes that basswood has been a failure, and that it was his opinion that a good many supplies would be left over.

IN the July *Review*, Mr. E. E. Hasty said that he believed friend Hutchinson needed less alteration to make him a model bee-editor than any other editor we have. Bro. York, of the *American Bee Journal*, in commenting on this, says: "Well, Editor Root (E. R.), that settles it so far as you are concerned. You might as well stop *trying* to be a 'model editor.' Need too much alteration." I have been puzzling my head to know whether Bro. York was trying to hit me or to hit the other fellows over my head. Let it fly. Seriously, I've only tried to be myself.

I OMITTED to mention in our last issue that Mr. W. A. Selsler, the branch manager at our Philadelphia office, 10 Vine St., had for his object, in his recent visit to the West, the securing control of a number of apiaries that produce strictly pure white-clover honey. His plan of operation among the bee-keepers, I think, is a very admirable one. While he represents us at Philadelphia the honey business is his own venture.

I remember of once asking him a question regarding the matter of buying honey on commission. Said he, "I can not answer. I al-

ways pay cash. I always feel sorry for the poor bee-keeper who sells his honey on commission." Mr. Selser has a warm heart.

A BEE-KEEPER, Mr. Robert Ayers, of Woodley, Fla., with whom A. I. R. once stopped, was stung in the back of the neck. The sting or stings caused a sore, and blood poisoning set in, resulting, we regret to say, in his death. If we were to moralize on this we should hardly be justified in concluding that the stings in this case resulted in death. Possibly a slight breaking in the skin at the same point would have caused the same result, for blood poisoning does sometimes set in, even from slight abrasions of the skin.

THE prospect is good for a fall flow of honey this year—at least around these parts. Frequent rains have made every thing grow luxuriantly. Sweet clover has grown so thriftily that around here at least it has almost all gone to seed; but the bees have worked on it busily for weeks. Honey has been coming in a little every day—just enough to keep down robbing and to keep the bees good-natured. The season has, therefore, been very favorable for queen-rearing. The asters and other fall flora are now just coming into bloom. Truly, great is the year 1897 for honey.

I FORGOT to mention in our last issue that our new type for the journal gives us about 12½ per cent more reading-matter than we had with our old type—that is, a gain of that much on the contributed matter and editorials, which were "leaded." On answers to correspondents, travels, and Our Homes, and all matter that was set with close lines, or "solid," as the printers term it, the reader loses about 5 per cent. But the total gain, on any estimate, is nearly 9 per cent over what we were giving our readers, taking the journal all through; and at the same time we are giving them a slightly larger letter than heretofore, which, our foreman says, he "specs" will be appreciated by the older readers.

#### THE ROOT COMPANY EMPLOYEES' PICNIC AT EUCLID BEACH PARK.

OUR employees this season have had an unusually long and heavy run. The force has been divided into day and night gangs, each of 11 hours' run. We have been so busy that we have had to run during Decoration day and the Fourth of July full blast. Working on holidays rather "goes against the grain" of working-people, and I do not blame them; but we had orders to fill, and honest obligations to meet.

Now that we are over the busy rush, the men have planned a big picnic on the 13th, to Euclid Beach Park, on the shore of Lake Erie, near Cleveland, about 40 miles from Medina. This involves a run of about 30 miles on the cars and 10 by boat. I wish all our readers might be present with us and enjoy the picnic with our busy workers of the Home of the Honey-bees.

We have had, during our heavy run of busi-

ness, about 180 employees. If these people take along their families, their "best girls," and their "best fellows," we may have a shlop picnic aggregating some 400 or 500. On that day our whole plant will be shut up, office and all, as tight as a box, with only a watchman and perhaps a clerk to take care of telegrams and urgent business.

#### THE '97 HOFFMAN FRAMES.

THE new end-spacing Hoffman frame met with an immediate and hearty reception; and, moreover, it seems to have been just what bee-keepers were looking for. Mr. Nysewander says his trade has been greatly pleased with them. There are only two staples used to a frame; and yet our records show that we have this season bought about a ton of them. There are 800 staples to the pound, or enough to make 400 frames; 2000 times 400 makes exactly 800,000. If this does not mean that the new end-spacing Hoffman frame is popular, I do not know what does.

I have experimented with and tested a good many kinds of frames, including quite a variety of closed ends; but I do not know of any thing that begins to suit me anywhere near as well as the new-style Hoffman. It can be handled twice or nearly three times as rapidly as the old-style unspaced Langstroth frames; and in these days of low prices on honey it means that we must make short cuts. Our '96 style of Hoffman was a good frame; but the '97 pattern is far ahead of it.

#### SMOKER FUEL; DRIED TWIGS AND PLANER SHAVINGS.

FOR years we have been using and recommending planer-shavings for smoker fuel. For a longer period of time Mr. Bingham has recommended stovewood split up into short lengths. Mr. Hutchinson, in a recent number of his journal, says it makes good fuel, but it burns out the smoker-cup too fast, and rather recommends planer-shavings, or fuel of that sort. At our basswood yard, having gotten nearly out of the excelsior sawdust (a fuel that is something like planer-shavings in its results) I made an attempt to piece out the fuel by breaking up, into lengths of four or five inches, dead limbs or twigs from the basswood-trees. A little excelsior fuel was lighted, and the cup filled up with broken twigs. It was very evident that, while the smoke was not as dense, it was much more lasting, and, except with the very crassest colonies, it gave very satisfactory results; and I am inclined now to believe that a combination of planer-shavings and soft dry wood would be more satisfactory, generally, than either alone.

#### SECOND CROP OF WHITE CLOVER.

WE can hardly say that the honey season is closed in this vicinity, and reports coming in would seem to indicate a like condition in other localities. There seems to be around here, at least, what we might call a second crop of white clover. This is particularly noticeable in the fields from which grass has been cut for

hay. The frequent rains have made sweet clover do better than usual, and have caused red clover (or peavine) to put forth its best efforts in honey secretion. While the bees have not made much of an attempt to store surplus since about the middle of July, they have held their own and a little more. It begins to look now as if we should not have to use extracting-combs containing sealed honey that has been set aside for wintering purposes. If the fall flow shall amount to any thing, very little feeding will be necessary. All of this, if general, looks toward prosperity for the bee-keeper. During a number of the previous seasons, the clovers (especially the white) have been killed out root and branch by the drouth. This year, clovers of every description are well rooted, and we may well hope, at least, for a good clover crop next year.

#### BIG COLONIES, AGAIN.

I HAVE said a good deal in our late issues in regard to the value of powerful colonies; and, as I have said before, I reiterate; I expect to say a good deal more about it. It is one of those things that will bear repetition; for I believe it is going to take a good deal of pounding to get the fact thoroughly into the heads of bee-keepers. Well, here goes for round No.—let's see—somewhere about seven or eight—call it eight—for I am sure I have harped on this question at least eight times.

I have noticed that a two-story eight-frame Langstroth colony, run for extracted, is just the sort of colony we need for producing comb honey. Take off the upper story with all its extracting-combs, that the bees have begun storing in, and place in its stead one super containing full sheets of foundation, and, my! how the bees go to work! If the colony is very populous it may be wise to put on two supers. I am not sure, but I am inclined to believe that a good way to start bees to storing honey in supers is to give them extracting-combs; and if the season is a good one, take the super away and give them supers prepared for comb honey. But the plan won't work a little bit unless the hive is fairly "biling" over with bees. The super that has been removed may be given to an extracting-colony to complete.

#### JOSEPH NYSEWANDER.

WE have with us to-day Mr. Joseph Nysewander, of Des Moines, Iowa, who is almost too well known to need any introduction here. Originally he was an obscure bee-keeper in New Carlisle, Ohio.

I remember very distinctly of our receiving a letter from Mr. Nysewander, at that point, offering his services as stenographer and typewriter operator, adding that he was using a caligraph. As we had no stenographer at that time he was engaged, and worked for us a time. He finally left us, and struck out for himself, buying supplies and doing some manufacturing. He shortly discontinued manufacturing, as he early discovered that the large factories could not only make supplies for him cheaper, but better goods as well.

Soon after, we began sending him supplies by the carload, for I believe he was one of the very first who bought goods of us in a wholesale way, and he has ever since been getting his stuff by the carload. During the past year he has already purchased of us *thirteen* carloads of goods, besides numerous small shipments.

He is a young hustling business man; and the rapid strides that he has made in the bee-supply line is no small credit to his enterprise and pluck. He is now on his return trip to Des Moines, having been to visit his father, who is very sick, and who even now is not out of danger.

#### A TWELVE-MILLION-DOLLAR GLUCOSE TRUST AND ITS SIGNIFICANCE.

IN our issue for July 1st I stated that it had been reported that the glucose-factories of the United States had formed a trust aggregating two millions of dollars, and added that I hoped this trust would put the price on the stuff up so high that it will not pay to use it in honey. Another item now appears in the daily press, to the effect that another glucose combine has been formed, aggregating something like *twelve millions!* If this is true, it goes to show that there must be an enormous demand for an article that is used, if I am correct, entirely for the purposes of adulteration.

By the way, it was somewhat of a query in my mind *why* this particular trust should be formed at *this particular time*. Then it occurred to me that it might be the tariff. In looking over the Dingley act I find glucose has a tariff of 1½ cts. per lb., the old rate being 15 per cent ad valorem. The new duty is heavy enough to shut out foreign competition; and now an enormous trust has been formed, it ought to be possible for it to run the price up to where I hope it won't pay to use it in honey. Let it go up. Honey has been coming down in price; and if it is true that glucose will be going up, all the better for the bee-keepers. It is when honey goes *up* and glucose *down* that the adulteration of honey is on the increase.

It is also reported that injunction proceedings will be begun against the formation of this big trust, under the anti-trust law. I don't know, but somehow I *hope* the injunction will be dissolved, and that the trust will shove the price up.

#### REPORTS IN REGARD TO DRAWN FOUNDATION.

VERY unfortunately the new dies were completed too late to get samples all over the country in time for the honey-flow. In the great majority of instances the honey-flow was either waning or had stopped at the time the drawn foundation was received, and the results were, therefore, somewhat negative in some instances. A lot we sent to Mr. F. A. Salisbury reached him just about the time the honey season was stopping. After putting the drawn foundation and full sheets of ordinary foundation in the same super on the hive, he wrote us, July 17, "Honey for the last few days has not been brought in as a short time before." . . . "The founda-

tion is drawn out about  $\frac{1}{8}$  inch; and the drawn foundation is fastened all around by the bees, and slightly bulged." Again, on the 20th of July, he writes: "I looked at the foundation and drawn foundation, and found both in about the same condition as on the 17th. It looks as though our honey season were at a close."

In the mean time we had written to Mr. George E. Hilton, knowing that willow-herb would follow later than clover, and asking him if he would test the drawn foundation. He immediately replied that he could, but asked us to send three supers, each containing half drawn foundation and half full sheets, to Mr. Robert, at Woodville, Mich. The supers were sent; and under date of Aug. 5th Mr. Robert writes: "At noon to-day the common foundation had cells fully as deep as the drawn, and much whiter and more uniform in appearance. Honey is not coming in very fast, and work in sections goes on very slowly."

This test so far would seem to be rather against the new article; but one swallow does not make a summer.

Mr. D. N. Ritchie, of Black Lick, O., who, I think, is speaking of the new drawn foundation, writes, Aug. 6th: "We took off the box containing the new-process foundation, and I must say it excels the natural—no fishbone, and *better to eat*." The fact that Mr. Ritchie compares the new process with the natural, and speaks of the "no fishbone," leads me to believe he was referring to the new drawn foundation.

Mr. B. F. Onderdonk, of Mountain View, N. J., had previously written us very favorably in regard to the new drawn foundation. In a later letter he writes:

The experimental super was taken off last evening, July 1st it was placed on a strong colony, and this, as I explained before, was near the end of the honey-flow, as the drouth had set in, lasting from the 20th of June till the 13th of July, without a drop of rain. July 10th I examined and found the new deep-cell foundation, and natural starters, fully drawn and honey stored; Dadant's full sheets half drawn; Van Deusen not touched.

It will be seen from this that the drawn foundation fully equals the natural comb, and that both were ahead of ordinary foundation. Assuming that Dadant's was equal to the best of ordinary foundation, here clearly is an instance where drawn foundation and natural comb were decidedly ahead; but it should be stated that the test was more severe because Mr. Onderdonk used narrow starters of drawn foundation—one at the top and one at the bottom. These in the above test were placed over against *full sheets* of ordinary foundation.

Mr. Onderdonk states further on that the space between the two starters, top and bottom, of the drawn foundation, was filled in with natural drone comb, and therefore the appearance of the comb honey from the full sheets of foundation was better because it was all worker; but, of course, if Mr. Onderdonk had had the full sheets of drawn that we are *now* making, the appearance would have been just as good, and the result decidedly in favor of the new product.

We also sent some samples of the new drawn

foundation to Dr. A. B. Mason. At the time of sending I told him that I knew he would give them a very fair and impartial test; and that if the thing did not pan out well I knew he would be prompt and fearless enough to say so, for he is one of those chaps who, if the other fellow does not like what he has to say—well, he does not worry much about it. He has tested the new foundation, and here is what he says:

The ten samples of drawn foundation (or whatever you call it) you sent me for trial came duly to hand. Eight of the pieces,  $3\frac{1}{4}$  by  $3\frac{1}{4}$  inches square, were put in two shallow super frames, four in each; and as the four didn't fill the frames to their full length a piece of newly built comb of about the same thickness as the drawn foundation was put in to fill it. In five days all was filled with honey, and nicely sealed over.

Having some company to dinner the next day after I had removed the honey from the hive, I thought it would be a good time to test it. One of the company I have known as a great lover and consumer of honey, eating it at nearly every meal for years.

Both kinds, the natural comb made by the bees, and the drawn foundation, were tested, and some said the drawn foundation was the nicer, but *none* thought the natural comb was any nicer, or less "gobby" than that from the drawn foundation; and the great honey-eater above mentioned thought the comb from the drawn foundation was the nicer, and preferred it to the other. For my own part I could not possibly make myself see any difference, except near the edges, and there our samples of natural comb were heavier than that from the drawn foundation.

A. B. MASON.

Station B, Toledo, O., Aug. 6.

The doctor's experience is more in line with our own; and it does not seem to me that there can be any question about the eating-quality of the drawn-foundation comb honey.

I will be frank about it and state that, in my opinion, there are times when drawn foundation may not show any particular advantage over ordinary foundation; but I am just as sure that, in a majority of instances, it will prove superior, as I am sure it is an advantage to use full sheets of common foundation instead of narrow starters of the same article.

Before any opposition came up at all, it was universally admitted last year that it would be a great advantage to use natural-comb starters in supers for the purpose of starting the bees to work in the supers. It was, however, admitted that, after the bees got once started, they might work just as well on foundation as on the natural comb. Mr. B. Taylor, a year or so before he died, called attention to the great value of drawn combs, and many another one fully indorsed it; and all the tests so far with the natural comb and the drawn foundation, both of the same depth, seem to show equal results. So we may assume that there will be a big demand for drawn foundation, even though we admit that there are times when foundation will give as good results.

You will see that I have endeavored in the above to state the facts fairly. I have not tried to bolster up drawn foundation any more than it deserves.

DON'T forget the big convention that takes place from the 24th to the 26th at Caton Hall, Buffalo. A. I. R., Mrs. E. R. Root, Leland, and myself expect to be present. See convention notes for rates. After attending the convention I expect to tour eastward among bee-keepers, part of the way on my wheel.

ON THE WHEEL AMONG THE POTATO-GROWERS.

On the next to the last day of July I started off to visit a relative about thirty miles away. Our boy Huber, fourteen years old, rather thought he could keep up with me on the wheel, and so he proposed to go along. When about half a mile from home I stopped to see my mother, who is living with my youngest sister; and finally two of my sister's children, aged respectively thirteen and sixteen, decided to make two of the party provided I would go slowly and rest often. Come to think of it, I guess it was the mother who enjoined the above conditions in case they went along with Uncle Amos. Neither of the girls had ridden a wheel more than two months; but they put off in fine spirits, notwithstanding the warm July weather.

When about ten miles from home I proposed a little "rest in the shade while we tried some lemonade." Now, that rhymed itself — you must not lay it to me. When we were seventeen miles from home I told the children it was time for my forenoon nap. We were near Fairlawn, a place where I often stop for rest and refreshment. The good people there promised to have dinner ready by the time I woke up, and all together I managed to get the children to rest nearly an hour.

A little further along we stopped at Mr. Miller's, where they grew those beautiful cold-frame cabbage-plants last fall. The Wakefield cabbages were all sold, but they were just carrying into the city of Akron great beautiful heads of Early Summer by the wagon-load. There seemed to be quite a discrepancy between the prices we get for cabbage on our market-wagon and the price paid by the largest wholesale grocer in Akron. They said their first Wakefields brought them 60 cts. a dozen, but they finally got down to 30 cts. His great heads of Early Summer, weighing from 4 to 8 lbs. apiece, brought only 2½ cts. by the wagon-load. Now, the price that we receive at retail is from 10 to 20 cts. apiece; but this large wholesale dealer pays, say, 2½ cts. a head. He turns them over to the retail grocer at perhaps 4 or 5 cts. The retail grocer trims off some of the leaves so as to keep them looking nice and fresh, thus reducing the weight, and sends them all over the city to his customers (you know it is the fashion to deliver goods nowadays, even if it is only a spool of thread or a paper of pins), and gets 10 cts. a head. Now, it looks as if there were pretty good profits here, and I confess I think so still. But, dear friends, you have your choice. Those who grow the cabbages can run a wagon to the consumer, and deliver them direct, and get the big prices; and the consumer can, if he chooses, get acquainted with the gardener, and go or send

right to the grower and cut short the profits of the middleman. We all know this; but, notwithstanding, where a man grows cabbages by the acre he sooner or later prefers to sell them to somebody who will take the whole lot right off his hands, and let him go to work raising another crop where the cabbages grew.

A little further along I stopped at the Atwood celery-farm. Mr. Atwood says his ground does not produce celery as well as it did years ago; and he thinks even muck land does better under some system of rotation. I found him and his men in the bunch-onion business. They have a fine crop of Southport White Globe onions, and they are putting three onions in a bunch, said onions being from the size of a hen's egg up to that of a small-sized goose egg. Such bunches retail for a nickel; but the man who grows them by the acre is glad to have them taken off his hands in quantities at *only a cent a bunch*. It is the same with cabbages. The middleman who consents to take these perishable goods by the wagonload must have a margin so he can deliver them at a low price to the retail grocer. The latter must have a profit, so that at times when they do not go off readily he can sell three bunches for a dime, or two for a nickel, when they begin to get a little old.

Mr. Atwood thinks that onions do finely after celery; and I suppose that, after growing onions for a while, the celery will be all right again.

While I talked cabbages and onions the children enjoyed themselves in exploring the gardens and grounds; and when I reached my cousin's farm, where Huber's cyclometer registered just 31 miles from our starting-point, the children felt so well that the two older ones declared they could turn right round and go back home before dark, and just enjoy the fun of it. I told them, however, they would do well if they made the trip after a good night's rest.

As our stopping-place was only three miles from Mogadore, Summit Co., O., my old boyhood home, we proposed to visit over there after supper. The children suggested taking their wheels; but I thought they had had wheeling enough that day. Mr. Wolf furnished us a big stout horse and surrey; and with his two children (a boy of twelve and a girl of seventeen) we had a merry party, I assure you. I presume the good people who lived in the cottage on the hill were somewhat surprised to see such a crowd marching into their quiet dooryard; but after I informed the good lady, that about fifty years ago my grandfather made my mother a present of that home, and that I lived there about 11 years during my childhood, she very courteously invited us to make ourselves at home all over the premises. Old familiar landmarks met me on every side. I walked around the octagon house, and climbed down the steps on the gravelly hillside; admired the beets, vineless sweet potatoes, lima beans, and other vegetables that still grew with such wonderful vigor on that gravelly hillside; then I pushed open an unused gate. After some groping among the bushes I found a well-remembered path, and

the children trailed after me down to the babbling brook. A good strong plank took us across to the old cold spring in the hillside. A little stone crock stood on a shelf above the spring. The dark-colored earthenware seemed to invite coolness. While dipping up the sparkling water I remembered the many times I have craved, especially during sickness, a cooling drink from that very spring. I passed the water around, and each and all declared they had never in their life tasted such refreshing spring water; and Huber said, "Why, pa, this is surely as cold as ice water." They had forgotten their ride of 31 miles, perhaps, and also that it was a hot July day; but, notwithstanding, I had to agree with them that that water was all my fancy and memory had painted it. I drank it again and again. The water from that spring does not need *boiling* to make it wholesome. And then I wondered if my digestion would not be good without the necessity of riding a wheel if I could live where I could drink daily from the waters of that celebrated Mogadore "cold" spring. The well-worn path down the hillside attests the fact that many besides myself had taken a fancy to this special spring. Cousin Wolf has a spring in a hillside right close to his dwelling; but the waters are hardly equal to those of this particular one I have been talking about. He was a little surprised when I told him that, for the small sum of \$9.00, he could get a little hydraulic ram that would send the water all over his house, and all over his farm, for that matter. Of course, the expense of the piping would be extra. We sat out under the shade-trees talking over old times. The young ladies thought they would retire; but Huber, as he lay in the hammock, said he thought he would not go to bed till "pa did." When I was ready to go, however, he did not respond. My cousin called to him; then he shook him. Finally I gave him a shake, and then—what do you think? Why, he declared he had not been asleep at all, and was sure he heard all we had been talking about; and I think he did—fifteen or twenty minutes before he needed such a shaking. I tell you, friends, a boy of fourteen, who is growing like a weed, needs lots of sleep, especially after he has ridden over thirty miles on the wheel in one day. By the way, dear father and mother, let me suggest to you to give the boy, and girl too, all the sleep they need when they are in their teens. Would you think it any thing strange if I were to tell you a little care to give them plenty of sleep and rest when they are growing so rapidly might lay the foundation for robust health and usefulness in later years?

Next morning the children were all right, and wild to try their wheels again; but Mr. Wolf promised to take us to visit Wilbur Feun's if we would wait an hour or two. On the way we picked up my relative, Dennis Fenn, and a little later we ran across Mr. Metlin, so we finally had five potato-growers together in council. I have not space to give you all of that talk; but I will *take* space to give you just one little item to show you how intricate and complicated is the matter of growing just a crop of potatoes.

Cousin Fenn took us over to a nine-acre field. The greater part of this field looked as his fields usually do. Every hill of potatoes was so much like its neighbors that there was scarcely a choice between them—no bugs, a perfect stand, all bright and thrifty. At one end of the field, however, there were perhaps twenty or thirty rows that were not up to the standard. You could tell the dividing line clear through the field. I suggested there was a different kind of seed. He shook his head. "Planted at a different time?" he shook his head again.

"Well, Wilbur, what makes the difference?"

He answered something as follows:

"You see, I have always advocated planting potatoes in loose ground. I did not believe it was best to roll the ground at all. I wanted it so the potatoes could expand and enlarge symmetrically without being squeezed out of shape by uncongenial surroundings. I put in my planter and started to plant the field without rolling the ground. When I had got thus far I did not feel quite suited with the way things were going, and so hitched on to the heavy roller, and rolled the rest of those nine acres. You see the result."

Now, this would seem incredible were not the object-lesson right before our eyes. Without a question, the use of that roller on that field of nine acres more than paid for itself in growing this one crop of potatoes. I strongly suspect that the low yield of potatoes per acre throughout our State of Ohio is owing to the fact that the farmers who grow them are so poorly supplied with proper tools for pulverizing and fining up the soil.

Finally the children were delighted to be permitted to step out of the buggy and take their wheels once more. We just flew over the cinder wheel-path between the White Grocery and Middlebury; and when we came on to the paved streets on the side of Akron toward our home, Miss Rena would anticipate me and run up hill like a young colt that had got started for home. I tried to have her stop long enough to see the beautiful residences along the suburbs of that Akron road, but I could not hold her back. We took a hasty dinner where we had dined the day before; but when about ten miles from home it was evident that the girls were becoming tired. We took long rests under the shade-trees beside the road. We washed our faces in the babbling brooks coming from hill-side springs, and I for one had a really restful holiday. We reached home at five o'clock, having made about 65 miles in two days. All declared they would like the fun of doing it all over again.

Now, dear friends, if your boys or girls are crazy for a wheel, give them the means if you can of earning one; and when they get it, watch over them and see that they make a proper use of this wonderful new gift that has so recently come from the kind Father above; and when the wheel comes, teach the children to make a good use of it. Do not let them ride far at a time. Have them take plenty of sleep and rest. Don't let them undertake a century in one day until they are men and women grown; but before that time have

them trained in the fear of the Lord so that never, under *any* circumstances, will they think of undertaking a century run on *Sunday*.

---

## OUR NEIGHBORS.

---

Thou shalt love thy neighbor as thyself.—MATT. 19:19.

For several years past I have had invitations to visit the great seedsmen, and look over their trial-grounds around the city of Philadelphia. There are perhaps more prominent seedsmen congregated in this city than in any other one spot on the face of the earth. I was told the best time for me to visit would be during the month of August. On Monday morning, Aug. 2d, while at the breakfast-table I noticed a low rate on account of the meeting of the League of American Wheelmen. To take advantage of this low rate I should have to go during the first week in August; and to be sure and get around without being away from home over Sunday, it was needful I should start in the fore part of the week. So all of a sudden I made my preparations and was off. Now, I do not propose in this department to tell you much about my visit to the wonderful gardens and seed-growing farms; but I will tell you of these things later. I love to study plants and high-pressure gardening; but I love to study humanity and my "neighbors" still more.

I soon found myself among a crowd of more than ten thousand boys and girls who love to ride the wheel. Some of them were doubtless pretty well along in life; but with their wheeling-suits they seemed to be youthful, at least for the time being. Perhaps I should tell you that I am and have been a member of the L. A. W. almost since it started. Of course, I am not in sympathy with Sunday riding nor with the racing business, as a rule; but for all that, I am in deep sympathy and in touch with all these people who are finding health, strength, and happiness through the proper use of the wheel. I am also in deep sympathy with the movement that the L. A. W. has inaugurated in the way of better roads and freer communication with our neighbors and the whole outside world.

I have frequently spoken of the facilities for wheeling in this, that, and the other location. I said the sandy desert of Arizona, in special localities, was the finest place for wheeling in the whole wide world; and when down in Florida I spoke with enthusiasm of the sandy beach, just as it was left by the briny ocean waves, so hard and firm that the wheel passed over it without leaving even a visible track; but when I got outside of the city of Philadelphia, and tried their beautiful cement roads, with their graceful curves up and down the slopes, with the green lawns and brilliant arrangement of flowers and foliage, with beds on either side, I decided I should have to take it all back, and admit that the suburbs of Philadelphia come nearer to being the wheelman's paradise than any other spot I have

ever viewed on the face of the earth. It would have done you good to see the way in which the boys and girls congregated there and enjoyed this privilege. Not only all day long were they seen spinning and flying in every direction, but even late at night. Yes, I myself was out until between ten and eleven on two or three occasions; and even at these hours wheels were flying with boys and girls. There were tandems in great numbers, and the front seat was almost always occupied by a pretty woman with her brother, husband, or lover—of course I could not tell which—just back of her. With every crowd of boys there were almost sure to be two or three girls; and may be this accounts for the fact that, during my stay of three days in the city, my ears were only once pained by hearing an oath, and this once was by an outsider and not by one of the wheelmen. May God be praised for so much; and if the constant presence of womankind among the boys out on their sports and recreation had something to do with the circumstance, then I am glad that it is the fashion to take the girls along, even in our athletic sports.

As soon as I arrived in the city I saw banners in every direction proclaiming, "Welcome, L. A. W." Hotels had the same welcome, with reduced rates, and the restaurants made it a business to provide a special low-rate dinner especially for the wheel-riders. Rides were planned on the steamers to the various pleasure-resorts, free to every one who showed his L. A. W. ticket. This ticket, let me explain, is given to every subscriber to the spicy little magazine entitled *The L. A. W. and Good Roads*.

Before I go any further, permit me to say that my heart has been rejoiced during the present year to know that the president of this great organization is a Christian man; and he has been doing some grand work in the line of discouraging Sunday centuries, as well as all kinds of Sunday racing, and things of like import.

Wednesday evening we had a beautiful boat-ride up the Delaware River, and then back again down the river to Washington Park. This park is an immense garden in the shape of a pleasure-resort. The ground around and between the trees is all covered with a smooth floor which is kept constantly neatly swept. Abundance of shade, excellent water, refreshing drinks, with ice-cream and refreshments in general, make it a pretty place right up to the water's edge. A Ferris wheel, very much like the one in Chicago (only 10 cts. for a ride), receives, of course, a large patronage. Toboggan-slides that start away up above the tree-tops, send boat-loads of passengers down a long steep incline with terrific speed, landing them in the waters of the little artificial lake. The boat strikes the water with such force that it skips with its living freight away up into the air, and bounds and rebounds again and again. Of course, the water flies in great torrents in every direction except toward those in the boat. With the splashing of the water, and the shrieking of the boys and girls inside, it makes a most animated scene.

When the boat was pretty well loaded, so the rebound was unusually great, it seemed as if some of the inmates were thrown nearly two feet above their seats; but as they clung together, and came down all right with no one hurt, the program kept being repeated all day and away into the night. Finally, when it was announced that one of our expert cyclers was to ride down that incline on a *wheel*, great crowds gathered all around the banks of the lake. We were afraid we should not be able to see him clearly; but when we found he carried a lot of fireworks attached to either handle-bar we were pretty well satisfied in this respect. Down, down he went, with terrific speed. It made me think of some of my adventures in going down long steep hills. Just when everybody was holding his breath, when the wheel was up to its very highest speed, the rider dropped his fireworks, and sprang from his wheel just in time to dive down into the water. He came up safe and sound somewhere out in the middle of the pool, then swam ashore while a boat near by fished out of the water his dripping wheel. Then the crowd was called up to witness the play of the electric fountains. This was much like the one at the World's Fair, except that it was much more elaborate. While we sat entranced by the brilliant sparkling sprays of the water, listening in the meanwhile to the most exquisite strains of music from one of the finest bands the world can probably furnish, through the misty waters some dim phantom-like object seemed slowly rising. Was it imagination? or were there really some letters that meant something through that sparkling, radiant combination of rainbow colors and sparkling waters? Oh, yes! there were the words, "Welcome, L. A. W.," rising right out of the water; yes, and there seemed to be human hands holding aloft a beautiful banner; and finally up out of the water itself came three Graces in woman form—veritable mermaids rising up out of the depths of the sea, holding aloft their banner. Somebody who stood by me said, "Surely, they can not be living figures, although they are astonishingly true to life." But at just that moment the central goddess—yes, she would have made a very good Goddess of Liberty—waved her hand and bestowed a most bewitching smile upon the crowds of American wheelmen. Now, this naiad who rose up out of the water was not clothed with very much of any thing; in fact, a water-nymph would not be supposed to need *very much* drapery, even though she appeared before a great audience. The dazzling spray and the rippling water clothed her as with a halo. I suppose you know your old friend who writes these Home Papers has been more or less critical in regard to things of this kind—circuses, theaters, and the like. Well, for once I was somewhat puzzled. The mechanical effects produced by these wonderful electric fountains were grand, and there was nothing objectionable about them. The accompanying music was also entrancing. The beautiful grounds and shade-trees seemed to make the place a little paradise on earth; and that figure of the beautiful woman, so artisti-

cally combined with the other environments, need not necessarily have been objectionable. If I am making any mistake, I pray that the Holy Spirit may set me right.

The next day our good friend Selser, who represents our Philadelphia house, insisted that I must make at least a brief visit to Atlantic City before leaving Philadelphia. He did not tell me what I should see, but asked me to trust him. Our passage of 60 miles was made in 55 minutes, including one stop; and this railway, so straight and level and beautiful in all its appointments, is in the habit of making this speed right along. If I am correct, it is the fastest train in the world.

Atlantic City is a place of 200,000 people—at least, that is the number at this season of the year. In the winter time it shrinks down to *twenty* thousand. I will tell you why; it is one of the most celebrated bathing-places in the world. It is all hotels, bathing-houses, and such places of business as usually congregate under such circumstances. When I first caught sight of a group of perhaps fifty or a hundred bathers on the shore, I wanted to stop a little; but friend Selser had a different plan. "Come," said he; "let us take a little stroll through 'Vanity Fair.' Perhaps that is not quite the proper name, but it may make you think of it. We will look at the bathers a little further on."

I have not time here to describe the beautiful pavilions, machinery of all sorts for pleasure and recreation, curiosities exhibited for sale from all parts of the earth, mechanical inventions in the way of electricity, chemistry, optics, etc. Finally we came to the center of attraction. Almost as far as the eye could reach, human beings were down in the surf getting health and recreation amid the deafening roar of the salt-water breakers. Hundreds does not tell the story. There were literally thousands of human beings, all mixed up, some under water, some on top of it, and all enjoying themselves. Mr. Selser did not urge; but when I expressed a wish to join them he said "All right." There was such a crowd for bathing-suits that we had to wait quite a spell. I soon became accustomed to men and women all around me in their novel dresses (or *undress*,) looking like a lot of frolicsome juveniles instead of grown-up men and women. My preconceived notions for a while rebelled against this sudden departure from ordinary decorum, but I made up my mind that it was my business to observe and inquire, rather than to criticise. The first thing that struck me was that such a bathing-place is of itself a great leveler. Poor people and rich people, as well as old and young, were all mixed up indiscriminately. The millionaire and his wife and daughters, when they threw off their costly clothing, also threw off, at least to a certain extent, their pride—and I came pretty near saying arrogance. May be it *is* the right word. It took me a little time to get over the chill of first going into the briny water; and, remembering that I had only recently thrown off my overcoat and fur cap, I felt a little anxiety. In a short time, however, I was tumbling around with the rest,

and laughing and shouting until I almost forgot to shut my eyes and mouth and hold my breath when the big foamy billows came surging over us. Friend Selser kept urging me to turn my back toward the wave when I saw it coming, for it might strike with such force as to hurt my face. There are two ways of meeting breakers. One is to dive through them, and the other is to jump up so your head comes out of the way of the water. At every wave, more or less of us tumbled down and got mixed up. Oh! but didn't we get clean with that tremendous washing and rinsing from the briny waves? Some of us were awkward, but nobody seemed disposed to be touchy or to complain. There seemed to be the utmost good nature prevailing everywhere. Everybody laughed at all that happened. Once or twice I saw some awkward country youth back up so as to jostle some fine lady, evidently of rank and culture; but his awkward apology was always accepted, even if it was hardly what the circumstances seemed to warrant; and with all the haps and mishaps of that delightful day I did not hear one unkind or even despondent remark. I am not sure that I even saw a despondent look.

Oh, dear me! why didn't it so happen that I might take a salt-water bath every day in the year? Now, then, is there any thing wrong about having all humanity bathe together in this proniscuous way? When you become accustomed to it, everybody seems at least decently and becomingly clad—that is, for the time being. If we would all remember to clothe our minds and *thoughts* in such a garb as we are sure would be pleasing to the great Father above, it would not matter so very much about this matter of dress. If everybody loved his neighbor with a pure and holy love (as in the language of our text), woman's dress might conform to season and circumstances, at least far enough to allow her to move easily and gracefully through her vocations in life. Perhaps we should need more often to pray, "Create in me a clean heart, O God, and renew a right spirit within me;" but such a prayer would only bring us nearer to God; and any circumstance or set of circumstances that would drive us oftener to the throne of grace might be a blessing in itself.

## IF YOU WANT BEES

that will just "roll" in the honey, and that are wonderful red-clover workers, also gentle to handle, and exceedingly hardy, then try **MOORE'S STRAIN OF ITALIANS**, the result of 18 years of careful breeding.

Warranted queens, 75 cts. each; 3 for \$2.00; per doz., \$7.00; tested, \$1.00; select tested, \$1.50; select warranted, \$1.00. Strong 3-frame nucleus, with warranted queen, \$2.50. Safe arrival and satisfaction guaranteed. Circular free. Those who have never dealt with me I refer to A. I. Root, who has purchased of me over 850 queens.

J. P. Moore, Morgan, Pendleton Co., Ky.

## QUEENS BY RETURN MAIL.

Daughters of best imported queen mother, warranted purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer, as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded.

L. H. ROBEBY, Worthington, W. Va.

## Queens Given Away.

Gray Carniolans and Golden Italians. We will give a fine tested queen (either race) to all customers ordering six untested queens, and a fine select tested queen to all who order 12 untested at one time. The queens given away will be sent to customers in August.

**WARRANTED Three and Five Banded Italian Queens at 50 Cents each.**  
**GEO. W. COOK, Spring Hill, Kan.**

#### BEESWAX DECLINED.

The demand for beeswax has slackened because the season for making comb foundation is practically over. The price is also on the down grade. From now on until further notice we will pay 25 cts. cash, 25 in trade, for average wax delivered here. For select lots of sun-extracted wax we usually pay one to two cents above the price of average.

#### CALIFORNIA EXTRACTED HONEY.

As I write this, our car-load of honey has just arrived from California. We shall be pleased to hear from those in need of honey who did not raise enough to supply their home trade. The honey is in 60-lb. cans, 2 in a case. Water white, in case lots, at 6½¢ per lb.; light amber at 6. Samples and prices on large lots furnished on application.

#### CLOVER HONEY, COMB AND EXTRACTED.

We are prepared to furnish both comb and extracted honey, gathered mainly from white clover, in large or small lots. Particulars and prices on application. As in years past, we will serve as a medium of exchange between those who have a surplus and those who do not have honey enough to supply their home trade. We shall be pleased to hear from both.

#### CANS FOR EXTRACTED HONEY.

We have just received from the factory a carload of over 3800 five-gallon square cans, most of them with the 2-inch lever seal. A few have 1½-inch screw caps with seal. These cans are the very best quality. Record make, and we can furnish either style, 2 in a box, in 10-box lots and upward at 80¢ a box; 50-box lots, at 77¢; 100 in cans at 55¢ a box, shipped from Medina. We can furnish cans with 1½-inch caps from Chicago, or St. Louis, Mo., at the same price.

We can also supply from Medina one-gallon cans with the 2-inch lever seal, in boxes of 100, at \$9.00 per 100—a special low price to reduce stock. These cans, put up 10 in a box, in lots of 10 boxes, at \$1.20. We have devised a screw-cap honey-gate to fit the lever-seal cans, which we can supply to those who require them, at the regular price, 15¢ each.

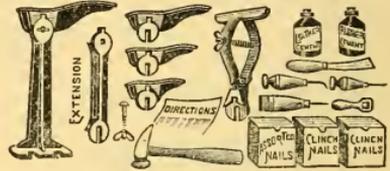

#### HONEY MARKET.

Although still early for selling honey, there is a fair demand, and prices seem to be pretty well maintained, and choice honey is already finding ready sale. Later reports show that, in many sections, the crop will be much less than at first anticipated. In the northern New England States there seems to have been very little honey gathered; likewise in Minnesota, owing to cool weather and rains, very little honey has been gathered from the white-clover bloom, which is very abundant. In Michigan the yield from willow-herb seems to be cut short. With abundant farm crops and fairly good prices; with the starting-up of so many industries that have been dormant or working on short time during the past three or four years, the demand for honey should be so improved that as good or even better prices should be realized than last year. If bee-keepers who have plenty of honey will not make the mistake of rushing it off to the large cities into the hands of irresponsible commission houses, but will, instead, develop their home market to the fullest extent, there will be hope for improved prices for honey instead of lower. If Americans generally consumed as much honey as they do in Europe there would be demand enough for a full crop of honey. Make sure that the consumer gets pure honey; and to help toward that end, join the United States Bee-keepers' Union, paying your fee of \$1.00, and thus furnish the sinews of war for the prosecution of those unscrupulous firms and individuals who palm off upon the unsuspecting public a mixture consisting chiefly of glucose, but under the name of pure honey. Such stuff does a great deal more harm to the honey business, by blunting and destroying the taste for honey, than in any other way. If people can get pure honey they will continue to eat it, while they will not continue so readily to eat the mixed stuff. Send your membership fee to Dr. A. B. Mason, Station

B. Toledo, Ohio; or, if more convenient, send it here. By sending us \$1.75 you can have GLEANINGS for one year, and membership in the U. S. B. K. U. Let the list of members roll up to large proportions so that the officers may soon have a fund with which to begin aggressive work.

#### GLEANINGS FOUR MONTHS FREE.

We wish to extend our subscription-list by several thousand names during the next few months. As a help toward that end we offer the remainder of the year 1897 for 25 cts. To those who send early we will mail the two August numbers, as long as we have a supply, as well as the remaining four months of this year. Will not many of our readers bring this offer to the attention of their neighbor bee-keepers who are not taking GLEANINGS? As an inducement to you to do so we make the following liberal offer:

ROOT'S HOME REPAIRING OUTFIT NO. 2.

We sold this outfit for years at \$2.00, and that is still the list price, and price at which it is usually sold. About a year and a half ago we reduced the price to \$1.50, and again last spring we made it \$1.35. We have quite a number of these outfits on hand which we desire to get into your hands where you can make them valuable in various kinds of mending. We will furnish one of these outfits, together with GLEANINGS for the rest of this year, for the price of the outfit alone—\$1.35. Now, if you can induce your neighbor to accept the offer above, put \$1.10 with the 25 cents he gives you, and send to us and we will ship you one of the outfits. If you wish to renew your own subscription at the same time, send us \$2.25 for GLEANINGS one year, to yourself the rest of this year (4 or 5 months) to a new subscriber, and the No. 2 repairing outfit. Or if you can not secure the new name we will send the outfit, with GLEANINGS one year, for \$2.00, the price you would ordinarily pay for the outfit alone. Please remember that, if you are in arrears on your subscription, all arrears should be sent in addition, as this special offer is made for subscriptions paid fully in advance.

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

#### SWEET CLOVER.

With the low price on clovers of all kinds, especially with crimson clover at only \$2.75 per bushel, we are going to be able to make a little better price on sweet clover; but as the crop is not yet gathered and hulled, it is a little difficult to say where the price will settle; but if you will write us what you want we can give you a special price which we think would be satisfactory.

#### GARDENING IN THE MIDDLE OF AUGUST.

You can sow beets for table use. Celery may be put out on very rich soil, where plenty of water is at hand. Grand Rapids lettuce should be started where you have a fall market, and you may establish a fall market in almost any locality. Now is just the best time to sow winter or Egyptian onion-sets. Put them in drills 2 feet apart, and 5 or 6 inches apart in the row. We have a splendid lot of sets just being gathered. Quart, 5¢; pk., 35¢; bu., \$1.00; 10 or more bu., 75¢ per bu. For description, send for our leaflet on growing onions to bunch up. You can sow all kinds of radishes, but don't forget the Chinese Rose Winter. It is one of the very finest, both in appearance and quality, especially for fall use. Spinach sown now will be ready to market this fall, and will probably not run up to seed before cold weather stops it; and, with a little protection, it can be wintered over outdoors. Purple-top White-globe turnips will be quite large enough for table use if put in at once. Whittaker onions, White Multiplier, and American Pearl, will need to be put

in as soon as the farmers are sowing wheat; but now is the time to get your ground ready, and order your sets or onions so as to have them on hand in time.

Last, but not least, this is the best month in the whole year to put out potted strawberry-plants with the view of getting a crop next season.

#### SEED POTATOES.

At present writing, Aug. 11, no one can tell what potatoes for seed are going to be worth the coming season. As eating-potatoes are worth 75 cts. to \$1.00 a bushel in most of our large cities, the prospect is that seed potatoes are not going to be very much cheaper. If you wish to send in your orders we will make the price as low as that of any other responsible potato-dealer.

#### NICK OHMER STRAWBERRY-PLANTS.

Orders are so far ahead for these that we can not take any more at less than 25 cts. each. This is for potted transplanted plants postpaid by mail.

#### CONVENTION NOTICE.

MR. EDITOR.—The next annual convention of the United States Bee-keepers' Union will be held in the main hall of Canton's Business College, corner of Main and Huron Sts., Buffalo, N. Y. commencing at 10 o'clock A. M., August 21th next, and closing on the afternoon of the 26th.

Those going to the convention should buy round-trip tickets to the Grand Army of the Republic encampment (not to the United States bee-keepers' convention), which meets in Buffalo on the last week of August. The G. A. R. have secured a rate of one cent a mile each way in the territory of the Central Passenger Committee, which is included by Toronto, Canada thence on a line to Fort Huron, Mich.; all of the southern peninsula of Mich.; Chicago, Peoria and Quincy, Ill.; St. Louis, Mo.; Louisville, Ky., and Pittsburgh, Pa. The Western Passenger Association and the Trunk Line Association make a rate of one fare for the round trip in their territory to places in the Central Passenger Association, from which points the fare will be one cent a mile each way; but tickets must be purchased to Buffalo from the starting point.

A. B. MASON, Sec. Station B, Toledo, Ohio.

The semi-annual meeting and picnic of the Seneca Co. Bee-keepers' Association will be held at Elm Beach 2 miles east of Haver's Corners, Tuesday, Aug. 31. The meeting will be opened at 10 o'clock A. M. E. R. Root will be present and participate in the discussions. A yacht has been engaged for the occasion; in fact, no pains will be spared to make this a profitable and enjoyable day. C. B. HOWARD, Sec'y, Romulus, N. Y.

The third annual meeting of the Southern Minnesota Bee-keepers' Association will be held in Winona, on Wednesday and Thursday, September 15 and 16 1897, commencing at 9 A. M. each day. All are cordially invited to come and bring their friends. E. C. CORNWELL, Sec'y.

## Second-hand Bicycles in Trade for Honey or Beeswax.

One Oronoco '97 gent's wheel, list price \$75.00, 24-in. frame, single-tube tires, steel handle-bars, 68 gear, decorated and finished in pea green, almost new, that we will sell for \$23.00. Will take honey or beeswax in trade at market prices. Also one girl's wheel, 24-inch wheels, cushion tires, for \$3.50.

#### THE A. I. ROOT CO., Medina, Ohio.

**Golden. }  
Adel. }  
Albino. }**

## Texas Queens.

Dr. Gallup says they are the best he has in his yard.

**J. D. GIVENS, Lisbon, Texas.**

## GERMAN CARP WANTED.

1000 this year's; 100 or more last year's. Prices must be reasonable. Send offers to **DR. WM. MOERSHEL, Homestead, Iowa.** Carp to be shipped in August or September.

## Wants and Exchange Department.

**WANTED.**—To exchange 16-section non-drip cases at Root's prices, laid down at your station, for fancy comb honey at prices to suit the times. Also second-hand 60-lb. cans, 2 in a case, valued at 25 cts. per can, freight paid, for gilt-edged extracted honey. B. WALKER, Ewart, Mich.

**WANTED.**—A location for a custom saw and feed mill. **W. S. AMMON, Reading, Pa.**

**WANTED.**—To exchange for extracted honey, 100 4-frame hives, new; one fine lot in Fort Worth, Texas; queens, Leghorn chickens. A bargain. Write quick. **G. RUTZAHN, Menallen, Pa.**

**WANTED.**—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules. **ANTHONY OPP, Helena, Ark.**

**WANTED.**—To exchange So. Omaha lot, value \$450, for gasoline-engine, lathes, or other machinists' tools, comb or extracted honey, or bees in Hoffman frames. **A. W. DUDLEY, 915 Locust St., St. Louis, Mo.**

**WANTED.**—To exchange Belgian hares, homing pigeons, White Leghorn eggs, or breeding-stock, for Italian queens from imported mother, pure-bred geese, ducks, ducks' eggs, or fowls. **EUGENE MANNING, Jacksonville, N. Y.**

### THE S. & H. CO.

desire to enter into correspondence with all contemplating the purchase of anything in their line. They think they have one of the most complete assortments of strong, smooth, healthy,

## FRUIT AND ORNAMENTAL TREES

Small Fruits, Vines, Shrubs, Roses, Bulbs, Hardy Herbaceous Plants, Greenhouse Stock, Etc., on the market and invite all buyers to come and see for themselves. They are to be found at the old stand where they have labored faithfully for the past 43 years to build up a reputable business. Catalogues free.

Address **THE STORRS & HARRISON CO., Box 8, Painesville, O.**

## Ajax Bicycles. Price only \$35.

We have sold a large number of these bicycles, and they are giving universal satisfaction. For instance, the following letters will explain:

"The Ajax bicycle arrived Saturday in good condition. It is entirely satisfactory in every respect. It is a handsome and easy-running wheel, and has the appearance of one put up for service. **FRANK WRIGHT,**  
Laporte, Mich., June 28, 1897."

"The Ajax wheel, Model 37, with baby-carrier (Kalamazoo) came all right, and it is really better than I expected; although I have learned that when The A. I. Root Co. say a thing is first-class it is as represented.  
"Thos. M. TODD,

Payson, Utah, July 8."

We have so much confidence in these wheels that three of them have been and are now in use in the Root firm; and E. R. Root expects to make his bicycle-tour on one of these through the East this summer. They are up to date, have large tubing, wooden reversible handle-bars. Morgan & Wright double-tube and single-tube tires, with option of gearing and option of height of frames, and a choice of finish.

We will sell these wheels and take in trade beeswax or first-quality honey at market prices. We have only a few in stock; and after those we have on hand are gone we will not dispose of more in trade.

A beautiful catalog, showing these wheels up in full, sent on application.

Medina, Ohio.

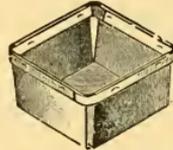

### One Man with the UNION COMBINATION SAW

Can do the work of four men using hand tools in Ripping, Cutting off, Mitering, Rabbling, Grooving, Gaining, Dadoing, Edging Up, Jointing Stuff, etc. Full line of Foot and Hand Power Machinery. Sold on trial. Catalog free. 1-24c

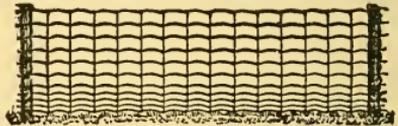

Seneca Falls Mfg. Co.,  
44 Water St., Seneca Falls, N. Y.

## Fruit Packages of All Kinds, also Bee-keepers' Supplies.

Order your supplies now before the busy season catches you. Price list free. Address

**BERLIN FRUIT-BOX CO.,**  
Berlin Heights, Erie Co., Ohio.

### A Fence Not Made By Hand.

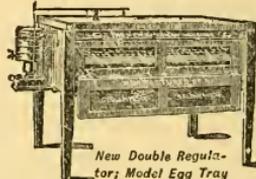

The average farmer can not afford to indulge in hand made fence, nor hand painted pictures. Even if he does the work himself, a "botch" and a "daub" will likely be the result, while the time consumed, if properly applied in his regular business, would provide means for beautiful photographs, engravings, etc., and lots of the "old, reliable" Page fence.

Honey Column.

CITY MARKETS.

NEW YORK.—Comb honey.—Our market does not open up until about September 1st, and we can not say as yet just how prices will rule. Still, it is our opinion that they will rule about the same as last year, viz., 12a/13 for fancy white and 10a/12 for off grades, 9a/10 for buckwheat. Extracted.—California is selling well on account of low prices. Arrivals are heavy. Southern is beginning to drag, and quotations have to be shaded in order to effect sales in quantity lots. We quote California white, 5a/5½; light amber, 4½/4¾; Southern, common, 5a/6 gal.; better grades, 5½/6@5½ gal. Beeswax steady at unchanged prices.

HILDBRETH BROS. & SEGELKEN,  
 120-122 W. Broadway, New York.

Aug. 21.

MILWAUKEE.—Honey market quiet, and values are almost nominal, as the demand is not very much. The receipts are fair, and the supply very good. We hope to sustain paying market values, but just now sales are slow, yet believe with the general revival of business interests the sweet will not suffer. White No. 1 12a/13; common, 8a/11; extracted white, in barrels, 5a/5½; in kegs and pails, 5½/6; dark, in barrels, 4a/4¼; beeswax, 26a/28.

A. V. BISHOP & Co.,  
 Milwaukee, Wis.

Aug. 21.

BOSTON.—The demand for both comb and extracted honey is still light, owing largely to the warm weather. We quote fancy white 13b, cartons at 14; No. 1 white, 13; light amber, 11a/12; white extracted, 7; light amber, 6; amber, 5; beeswax, 27, and wanted.

BLAKE, SCOTT & LEE,  
 Boston, Mass.

Aug. 21.

CHICAGO.—There is a little white comb honey selling, and chiefly at 12c, while some will not bring this price owing to improper filling and crooked combs. Extracted without much change, and slow of sale. White, 5a/6; amber, 4a/5; dark, 3½, some selling at less; beeswax, 26a/27, and quick sale.

R. A. BURNETT & Co.,  
 163 South Water St., Chicago, Ill.

Aug. 21.

ALBANY.—There is but little to report about our honey market at present. The old stock of comb honey is nearly cleaned up, and not enough new in yet to determine prices it will start off at, and quotations would be merely fictitious.

CHAS. McCULLOCH & Co.,  
 Albany, N. Y.

Aug. 10.

CINCINNATI.—No change since our last. Demand is good for comb and extracted honey, with a good supply. We quote choice white comb honey at 11a/13, while the range of prices for extracted honey is 3½/6, according to quality. There is a fair demand for beeswax at 26a/25 for good to choice yellow, with fair arrivals.

CHAS. F. MUTH & SON,  
 Cincinnati, O.

Aug. 21.

DENVER.—There is no material change in our honey market; it is very quiet. Fancy white, 11; No. 1 white, 10; No. 1 extracted white, 5. We are hoping for better trade after Sept. 1.

R. K. & J. C. FRISBEE,  
 Lock box 1014, Denver, Col.

Aug. 23.

KANSAS CITY.—The demand for honey has been very light the last two months, but is improving now. We look for good trade. We quote fancy 1-lb. comb white, 12a/13; No. 1, 11a/12; fancy amber 10a/11; No. 1 amber, 9a/12; fancy dark, 8a/9; No. 1 dark, 7a/8; extracted white, 5a/5½; amber, 4a/4½; dark, 3½/4; beeswax, 22a/25.

C. C. CLEMONS & Co.,  
 Kansas City, Mo.

Aug. 21.

NEW YORK.—New comb honey arriving in small lots. Trade rather quiet, as our market opens about September 1st. We quote State white-clover fancy comb at 12½/13; poor to prime, 10a/12. Extracted honey arriving in plenty; some trade, but not much activity. We quote California extracted white at 5a/5½; light amber, 4½/5; New York State white clover, 4½/5½; New York buckwheat, 3½/4; Southern, in bulk, per gal., 50a/75.

FRANCIS H. LEGGETT & Co.,  
 Aug. 19. Franklin and Varick Sts., New York.

PHILADELPHIA.—Honey arriving freely, and some demand springing up. We quote fancy comb at 13½; No. 1 white, 12; extracted buckwheat, 4; white, 5½; amber, 4½/5. We are producers of honey, and do not handle on commission.

WM. A. SELSER,  
 Aug. 24. 10 Vine St., Philadelphia, Pa.

MINNEAPOLIS.—Fair demand for fancy clover white at 10a/12, possibly fraction more. Other grades accordingly. Best extracted at 5a/5½.

S. H. HALL & Co.,  
 Aug. 23. Minneapolis, Minn.

COLUMBUS.—Fancy white clover, 12½; No. 1, 11. Local market is pretty well supplied by farmers who are now drawing some of their crop each day. We look for an increased demand by September 1st, but no increase in prices. Present supply is light.

THE COLUMBUS COMMISSION & STORAGE Co.,  
 Aug. 21. 406-413 N. High St., Columbus, O.

DETROIT.—Comb honey, fancy white, 10a/11½; extracted, 5a/5½; beeswax, 25a/26.

M. H. HUNT, Bell Branch, Mich.

Aug. 21.

FOR SALE.—25 bbis. extracted pure white-clover honey, very light in color, and of finest quality, at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—A lot of good extracted clover honey in 60-lb. cans.

JNO. A. THORNTON, Lima, Ills.

WANTED.—To buy quantity lots of fancy comb honey in non-drip cases.

B. WALKER, Evart, Mich.

WANTED.—To buy for cash, comb and extracted buckwheat honey; also white clover extracted or amber.

F. W. DEAN, New Milford, Pa.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer I write for a circular. I do not think the 4-inch Smoke Engine too large.

January 27, 1897.

Truly, W. H. EAGERTY, Cuba, Kansas.

Bingham & Hetherington Uncapping-knife.

T. F. BINGHAM, Farwell, Michigan.

## 4 Months' Trial Trip for 25c.

The weekly **American Bee Journal** would be a great help to you in your work with the bees. Better have it the last four months of 1897 for only 25 cents, if you are not already a subscriber.

The **Buffalo Convention Report** will be published in the **Bee Journal** *in full*, right after the meeting, beginning early in September. That report alone will be worth many times the 25 cts. Send for free sample copy, anyway. Address

GEO. W. YORK & CO., 118 Michigan St., Chicago, Ill.

# GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

Published by THE A. ROOT CO.  
\$1.00 PER YEAR MEDINA, OHIO.

VOL. XXV.

SEPT. 1, 1897.

No. 17.

## STRAY STRAWS

FROM DR. C. C. MILLER.

ON THE MORNING of August 18 I saw a bee here and there on buckwheat, with the thermometer at 58°. At 61° the bees were thick on it.

J. A. BUCHANAN, p. 589, has customers who always eat a dollar's worth of honey before it candies. Now, is that because his customers are so fast at eating, or because his honey is so slow at candying? [Probably both.—Ed.]

A MANUFACTORY of printers' rollers informs me that they use a considerable quantity of extracted honey in their business, but require the pure article, and prefer white clover or basswood. Under no conditions will buckwheat honey do.

IS IT NOT just a little inconsistent to charge with hostility, and trying to get the funds of the old Union, those who have advocated amalgamation? Why, I think most of them are members thereof, and one is not generally hostile to himself.

THE GROOVED BELLOWS-BOARDS for smokers will allow the use of a lighter spring, making it much easier on the muscles of the hand. [That is so. I never thought of it. For 1898 we will bear the fact in mind, and endeavor to have the tension of the springs slightly reduced.—Ed.]

IT'S SURPRISING, considering the times and all the circumstances, that the new Union should already have a membership of 175, with a still continued up-grade tendency. [The new Union is growing at an astonishingly rapid rate. If it keeps on growing it will soon be bigger than its elder sister.—Ed.]

SMOKER FUEL, like so many other things in bee-keeping, is somewhat a matter of "location." It isn't so much what is best as what is most convenient. One of the most generally convenient, and at the same time one of the best, is the small chips about any wood-pile. For a sharp, telling smoke, lasting as well, I know nothing better than sound osage-orange wood.

WITHIN TWO RODS of my home apiary is a field of buckwheat on which bees have been working some days. They work a short time early in the day, but I can see no buckwheat honey in the hives, neither is there any buckwheat smell either about the hives or in the field until this morning, Aug. 18, when the air about the field is well perfumed.

FALL HONEY is usually darker than the earlier; but at my south apiary this year, and to some extent last, the rule is reversed. For two or three weeks the bees have been filling sections with the whitest comb and honey, I think, I ever saw—much whiter than clover, and of excellent flavor, as mild as alfalfa. The sad part of it is, I haven't the slightest idea what it comes from.

"IN AN APPLE ORCHARD where the trees are so large and the branches so long that the twigs can shake hands with one another is an ideal spot for an apiary."—*Bee-keepers' Review*. Just the idea, and nicely expressed, W. Z. But my south apiary has something I like even better—a grove of young burr-oaks. No, burr-combs are no worse there than in the other apiaries.

THAT ITEM, "Big Colonies, Again," p. 604, gives something to think over. With two stories I can have whopping big colonies that store enormously in combs and never think of swarming; but somehow I can't make a success of having them work in sections. Is it possible that I can make the thing go by first starting them on extracting-combs and then switching off on to sections? Just wait till next year.

I WANT TO INDORSE what you say, friend A. I., page 607, about giving young folks plenty of sleep. The time gained in 24 hours by taking it from sleep will have to be paid back in later years with interest severely compounded. And when one gets on the shady side of 50, I know of nothing more refreshing than "tired nature's sweet restorer, balmy sleep." As Sancho Panza said, "Blest be the man that invented sleep!"

WORKERS reared in drone-cells, as mentioned by Elias Fox, p. 599, is a more common occurrence than generally supposed. More than 20 years ago I saw workers hatch from

drone-cells in a piece of comb sent by R. R. Murphy to the *American Bee Journal*. The queen may control the sex of the egg by her will; but the case you cite is no proof of it, friend Fox, for I think you will find that, before the queen laid in the cells, the workers laid a heavy rim of wax, making the mouth of the cell as small as that of a worker-cell.

IT ISN'T EASY to get up any rules for grading that will be satisfactory. Too much wording is bad, but too little may be worse. Editor Hutchinson wants every thing short and simple, but on the same page says he "would not have any pollen in a fancy grade of honey, and not more than half a dozen cells in a section of the second grade." Now, how are you going to have any thing of that kind carried out unless it is "so nominated in the bond"? [If the Buffalo convention does not adopt some set of rules, I propose to adopt something for GLEANINGS. The grading-rules that we have been using till lately were, as I understand, far better than nothing. But I believe I can improve on them after all that has been said and written, and I shall certainly make the attempt if the Buffalo meeting does nothing.—Ed.]

LOOK HERE, Ernest; those glucose-men are not fools, but sharp business men. No matter how solid the trust, they're not going to put the price where it will prohibit the use of glucose as an adulterant. Not the greatest profit per pound, but the greatest aggregate profit is what they're after, and that depends on the great amount sold rather than on the price per pound. [Yes, I am well aware that the glucose-men are shrewd; but sometimes shrewdness gives place to folly, and I was in hopes they might be so very "smart" that they would put the price of glucose up high enough so it would not make such inroads on honey. The very object of the trust is to put up the price; and even if they shove the price up only a little bit it will make it just that much less profitable to put it into honey. Extracted honey is coming down, or has been; and if glucose goes up, there will be less adulteration than formerly.—Ed.]

WOULDN'T I LIKE to have been at that picnic of the Root employees! A number of nice people among them I'd like to see again. Say, Ernest, why don't you give us a picture of them? [Yes, indeed, and we would have counted you as one of us. We made up a train of seven coaches and a baggage-car. On either side of the train was a mammoth sign, painted on canvas, with the wording, "The A. I. Root Co. Employees;" and on the pilot of the locomotive was a beautiful yellow queen-bee carved out of wood, about a yard long, with wings spread, ready to lead our big swarm in its flight to pastures new. The carving was done by Mr. Karl R. Mathey, who is still in our employ. The queen was richly painted, and decorated in gold. If she had not been such an awkward thing to carry we would have taken her to the Buffalo convention, and had her suspended in midair in the convention room.

Well, the picnic was a grand success in every

way. Nearly every seat in the train was filled with people, the great majority of whom were those who receive their bread and butter from the A. I. Root Co.'s pay-roll. Just before the train started I had the ever-ready Kodak; and after I had taken several shots the conductor called out, "All aboard!" and the train soon steamed into Cleveland. Arriving there we all piled into a lake steamer, and after an hour's ride we found ourselves at Euclid Beach Park.

We expect to make this shop picnic an annual affair. Ere another year rolls by we shall hope that Dr. Miller and a good many more of our bee-keeping friends will accompany us to some beautiful spot in fair Ohio.—Ed.]

DRAWN FOUNDATION doesn't show the advantage I expected over ordinary foundation. As to eating qualities it's all right, and I can't help thinking that the war that has been waged against it without knowing any thing about it is the maddest, blindest, silliest piece of folly that has occurred in the ranks of bee-keepers for some time. [There is only one other besides friend Doolittle (see editorials) who has reported the eating quality of honey from drawn foundation as not being equal to that of the ordinary comb honey. While I do not in the least doubt Mr. Doolittle's statement, I believe that, in the great majority of instances, the eating quality of the new product will be up to the required standard. It certainly has been in our own various tests at Medina, and with Dr. Mason.

You and Mr. Doolittle probably tried the drawn foundation and common foundation in alternation, as we advised. We have since discovered that this is hardly a fair test. Half of the supers should be filled with one kind, and the other half with the other sort. When the two lots are placed in alternation, the bees seem to feel that the foundation must first be pulled out to equal the drawn foundation; for it is contrary to their notions of hive architecture to have every other comb in the super or hive drawn out and the others neglected. They must all be drawn out in one portion of the hive, at least, together. We have found it to be true that, when the pieces were placed in alternation, in some instances there was no practical difference; but when the super was divided in halves, there was a difference in favor of the drawn foundation, the latter being accepted and filled with honey, while the common foundation in the other half was almost neglected. For instance, before me is a super that had been prepared in "halves," as above explained. The sections of one outside row, having had foundation in them, show the following weights after the season was closed and the weight of sections when removed from the hive: 1 oz., 4 oz., 7¼ oz., 7¾ oz. The sections in the opposite outside row had drawn foundation. These are the respective weights: 12½ oz., 13½ oz., 13¾ oz., 13½ oz. The other sections having the drawn foundation were finished sooner, and are fatter and heavier than the corresponding sections from common foundation. In relation to the same point, R. F. Holtermann, of the *Canadian Bee Journal*,

writes: "My own test of the deep cell goes to show they accept it much more readily than other foundations. I put one section in the far corner of the hive where they are less likely to fill it, and this was built out much farther than the sections near the center. They take next best to the 11-square-foot-to-the-pound new process."—ED.]

## THE BEE-KEEPERS' UNION, ONCE MORE.

An Interesting and Valuable Article.

BY PROF. A. J. COOK.

I am reluctant to speak further upon the above subject; but Mr. Newman's letter in July 1st GLEANINGS, and the importance of the subject, impel me to a further word.

I am very sorry if I misquoted Mr. Newman, and even more sorry if I misrepresented him. I have had high appreciation of his services, and have had only the kindest feelings regarding him. I am sure I need not say that any thought of antagonism to him has never been in my mind.

### HISTORY.

In the last vote, I believed (and I think many others did) that we were voting only on the question of amalgamation. I voted no—not that I was opposed to amalgamation *per se*, but only because I felt that many of the members were, and that we should not force the change upon them. It seems to me to-day that this was a correct position. Others thought the Union should not be tied to the National Association, or at least that such a marriage would not be wise, and hence the large vote against amalgamation. I did not suppose the failure to amalgamate would result in the formation of two Unions; but, the rather, if the marriage was not consummated, the old Union would lock horns with adulteration—would hitch on its whole force to aid co-operation, and would eagerly grasp any lever that would help to raise bee-keeping to a higher plane of success.

### THE STATUS TO-DAY.

Amalgamation was lost. We have two organizations, kindred in their general plan and make-up, requiring the same machinery for their work—the one tied, possibly by vote of its members, though I am not sure of that, but certainly by the views of its manager, to one limited, and, as it seems to me, rather unimportant line of work at the present time; the other, ready to attack any evil that really threatens the life or welfare of our industry. What a chance the old Union is losing now in not marching against adulteration here in California, where every thing would favor success! We have a good law, manager on the ground, and public sentiment all on our side. We could almost certainly have won a grand success, and secured a precedent that would have been as powerful for good as the Arkansas court decision gained previously by

the Union. It seems to me that, in case we could not constitutionally grapple with this foe at this opportune time, we should have taken steps at once to secure the right and power to do so.

### THE FUTURE.

I fully believe that we can afford but one organization. This seems so axiomatic to me that I believe the bee-keepers generally will concur. As the new Union seems more broad in its scope, more alive to the needs of bee-keepers, more ready to attack the enemy in whatever form he may take, I believe it wise to merge the old Union into the new. So far as I have heard expression, this seems the growing opinion.

I wish I could be at Buffalo to join in a calm, dispassionate consideration of the whole subject. Surely, the discussion should come, and the matter of a second submission to vote be carefully weighed. I presume a large number of the members, and a goodly proportion of the officers of the old Union, will be present, and I hope that they will make themselves heard.

### CO-OPERATION.

Southern California is now struggling with the subject of a "Bee-keepers' Exchange." The organization is on foot. A goodly number of bee-keepers have joined its ranks, and it has already done good service in securing to its members reduced prices on their supplies. It now remains to be seen whether it will be able to secure a better market than could have been had if it had not been formed. We hope and believe it will succeed in this respect, and, what is quite as important, that it will be able to convince bee-keepers, whether in or out of the association, that it has done so. Apparent as well as real success is needed. The "Citrus Fruit Exchange" proves conclusively that co-operation is the greatest need of agriculturists in all lines. It is almost universally admitted that the "Fruit Exchange" has been a signal success, and a great boon to the pomology of Southern California; and yet this important organization has been handicapped because so many held aloof. Farmers are all unused to such methods; are suspicious of them, and will not easily be convinced that they are necessary, safe, and desirable. Will bee-keepers be any more ready to co-operate? I have had great hopes of the bee-keepers, as I think they are a very intelligent class; they nearly all read and think, and it would seem that most have had experience that would lead them to think favorably of co-operation. Such methods promise immense advantage, and so are sure to come in time. Just how soon is a very important question. The success of the Fruit Exchange has resulted in far better grading and packing, at a reduced expense; has lessened cost of transportation; has secured better prices, and, perhaps, best of all, has developed new markets, and arranged such intelligent distribution that any single market is seldom glutted because of a rush of fruit into it. Such a rush into New York or Chicago is ruinous to prices the country over. I believe

a good bee-keepers' exchange could accomplish as much. I hope and believe that the time will soon come when the bee-men and fruit-men will unite forces, for the agents east could as well develop a market for both commodities as for one, and at the same time.

One of the chief objections to such a system is the fact that many are poor, and need ready money before the close of the season, and can realize on a prospective crop with a local dealer. The Bee-keepers' Exchange has arranged, as we are informed, to partially remedy this evil this season; and it is certain that, to realize on a coming crop in the usual fashion, is always very expensive. Such loans are secured at an enormous interest. I believe we all ought to write, talk, and work for the exchange system. Such methods in rural pursuits are so new and strange that we must patiently await their development. Perfection can not come at once. Mistakes must be made. The greatest difficulty is to find able, experienced business men who will work unselfishly and earnestly for the Exchange. The fruit-men are succeeding in this, we think, and are winning a success that is fast gaining the confidence of the fruit-growers. Their success will bring confidence to the bee-keepers as well. We believe that the bee-keepers here have been very fortunate in their choice of men to man the Exchange. We hope that the bee-keepers will rally more and more to its support.

#### NOTES.

I was interested in the note in Aug. 1st GLEANINGS regarding color of queens, drones, and workers. We have selected simply for color in workers, and hence the want of uniformity in the color of queens and drones. If it is necessary we can soon breed to uniformity in queen and drones; but is it? I have always believed that color in workers should be considered secondary in importance. The main thing is to develop a business bee, and color should be considered only to gratify a love of the beautiful, and to aid us to secure a proper label.

I agree with you regarding glucose. While possibly "vile stuff" may be too strong, yet an article that is often unwholesome, that is almost always used for evil purpose, and that actually injures many of our staple articles of commerce, should certainly be denounced. The editor of the *Los Angeles Times*, in to-day's issue, speaks of a new "glucose-factory," and adds that means *micro* honey (?), pure (?) syrup, etc. The real character and standing of glucose is everywhere well known. There is no need of our speaking its praise or defending its character.

The article of Mr. Sladen, on *Apis dorsata*, is excellent. I am surprised that its tongue is so little longer than that of the *A. mellifica*. Its size is certainly against it. The larger insects are always more logy and inactive. Our common bees are surely about typical in size among insects. It is more than likely that *A. dorsata* would be a failure with us. This is why I have always urged that government should import it. I do not think private

parties should be asked to undertake such enterprises as *may* bring signal advantage, but *usually* result in no improvement. We must keep trying to secure the occasional prize, like the navel orange; but the trials should be made by government, not by any one man. If individuals wish to do such work, well and good; but it is often unwise for government to wait for them. The same logic holds for experimental research, which all the most civilized governments now foster.

I was specially glad to read Mr. Doolittle's article on clipping queens' wings. I can remember when I was almost alone in its advocacy. There is another advantage not mentioned by Mr. Doolittle. An apiarist can leave his apiary at swarming time in the care of wife or child, and go to other work. The one in charge has only to cage the queen and note the hive; and when the bee-keeper comes at noon or night he can attend to the bees. I have often known farmers to manage quite large apiaries in this way.

It is gratifying to note that common advice and legal enactments now say, "*Never* spray until the blossoms fall." Recent discoveries regarding egg-laying by the codling-moth make the delayed spraying all the more reasonable. It is folly, aside from the bees, to spray before the blossoms have all fallen.

The article on page 493, regarding cane sugar, I think contains several errors. I wish it might be submitted to Dr. Wiley for a review. I think the cane sugar in the nectar, in the honey, on the table—everywhere—is the same, only in different form, just as the salt in the ocean and in the salt-dish are the same.

Long Beach, Cal., Aug. 5.

[The scheme of the California Bee-keepers' Exchange is most admirable, and should be most heartily encouraged. GLEANINGS will gladly do any thing that will help it along.]

The new Bee-keepers' Union is progressing finely, and already has a membership of 175; and indications are that it will surpass in membership and funds the old Union. Whether it does or not, the old and the new should be combined—or, if you please, amalgamated. Economy and cool business sense both urge it. I am in hopes that the Buffalo meeting will produce a constitution that will be acceptable alike to the members of the old and new Union.

Regarding *Apis dorsata*, permit me to offer this suggestion: The A. I. Root Co. will be to no very great expense to start on, and may, for a very small sum, be able to secure *dorsata*. If it fails, then there will be time to advocate the use of Uncle Sam's money. We shall probably know within a year what we can do. I expect to make up this afternoon a list of hives and implements necessary to equip Mr. W. E. Rambo, so that he can properly test *Apis dorsata* and other species of Indian bees.

Regarding the article on cane sugar, p. 493, I respectfully submit it to its author. In the mean time I have sent a copy containing the article to Prof. Wiley himself.—ED.]

### IMPORTANT ITEMS.

**Pettit's System of Producing Comb Honey; Monnier's Cure for Bee-paralysis a Success.**

BY EARL C. WALKER.

During the honey season which is just drawing to a close I have given Pettit's plan of taking comb honey a trial, in part. I consider the scheme of placing wedge-shaped pieces of wood under the sides of the hive, thus causing the bees to distribute themselves to the sides and back end of the hive, the most valuable feature of the system. By this means the bees with their loads of honey are sent directly to the outside sections, which will be filled as soon as those in the center of the super. Instead of sawing out wedge-shaped pieces of pine, as described by Mr. Pettit, I simply get some ordinary shingles, which taper down to a thin edge, and split them up into strips  $\frac{7}{8}$  inch wide. These are placed under the sides of the hives, as directed by Mr. Pettit. This not only causes the bees to fill the outside sections, but gives abundant ventilation, which is so necessary in the hot summer months. I had several colonies that seemed determined to hang out and loaf. I placed the strips of shingles under the edges of the hives, and the bees quit loafing, and went to work in the sections. One of these gave a surplus of 72 lbs. of comb honey. I will keep the strips under the hives until winter, for ventilation.

#### MONNIER'S CURE FOR BEE-PARALYSIS.

I have cured several cases of bee-paralysis this season by running healthy swarms into hives containing affected colonies. The healthy bees would at once attack the diseased ones, and carry them off. In most cases I let the diseased bees swarm, and then the next healthy swarm that issued I ran into the hive out of which the diseased swarm came. The diseased swarm I ran into a hive out of which a healthy swarm had issued. The disease has entirely disappeared. All that seems to be necessary is to mix a diseased and a healthy colony together, and the bees do the rest. The scheme of uniting diseased colonies to cure paralysis was given in GLEANINGS on page 447, and I used the above method of putting it into practice. All bee-men should try this cure, and report the result. Mr. Monnier, who discovered this, deserves a vote of thanks from all bee-keepers. When I read his article, I, like you, Mr. Editor, had my doubts about its being a certain cure. But I have tested it for myself, and am positive that it is a sure cure. Try it and see.

#### A COMMON MISTAKE IN TRANSFERRING.

A great many bee-books, in giving directions for transferring, advise the use of a driving-box of the same size as the box hive to be transferred. For example, Mr. F. Benton, in *The Honey-bee*, p. 72, says, "Invert the hive, and place over the open end an empty box, or the frame hive itself, making whichever is used fit closely on the hive (Fig. 53). He emphasizes the importance of having the driving-box fit closely, by a half-tone engraving. Now, I have transferred a great many bees, and I be-

lieve it is entirely unnecessary to have the driving-box fit snugly over the end of the box hive; in fact, if the weather is at all warm it is quite an advantage to have the driving-box some larger than the box hive. The bees run up into the driving-box more readily if it is large enough to project a few inches over the sides of the hive, thus giving plenty of ventilation.

#### THE HIGGINSVILLE COVER.

The Higginsville cover has not proven as satisfactory with me as the old flat cover used on the Dovetailed hive a few years ago. It warps, leaving a crack along the top edge of the hive where the cover and the hive-wall meet. Besides, it is too thin for winter where the bees are wintered in single-walled hives. The space left by the cover warping allows the escape of heat from the cluster, and this causes a draft through the hive. I have been testing the new gable cover, and so far find no fault with it. By using it, shade-boards can be dispensed with; and in the winter the space can be closed, thus making an air-space above the cluster.

New Albany, Ind.

[I wish others would try this new cure for bee-paralysis. The fact that it has worked successfully in two cases is very encouraging.—ED.]

### REPORT ON TUNIS AS A HONEY-PRODUCING COUNTRY.

BY THOMAS B. BLOW.

[We take pleasure in presenting to our readers a portion of the report of Mr. Thomas B. Blow, of England, made to the Tunisian government, North Africa. The parts omitted refer to the size of frame best suited to that country, and the probable profits of the industry.—ED.]

*To the Department of Agriculture, Regency of Tunis.*—I have the honor to report that, during the past two months, I have given great attention to the question of apiculture in Tunis. So far as I have seen, there are certain parts of Tunis that are, in my opinion, absolutely without equal in any part of the world for their capacity to produce large quantities of honey. These districts are the hills, on which grow vast quantities of rosemary (*Kosmarinus officinalis*), heath (*Erica multiflora*), and many other honey-producing plants. Of such districts I imagine Tunis possesses some millions of hectares, and in the greater portion the honey is absolutely wasted for want of bees to collect it. Not only can honey be produced here in great quantity, but the quality is also superb; in fact, there can be no finer honey than that produced during the winter and spring months from the heath and the rosemary. The climate is well suited for apiculture, for the bees are able to work a great portion of the time that these plants are in flower (there being no winter in the sense we understand it in Europe). The heath and rosemary commence to bloom in November and December, and continue till March or April, and during these months the bee-keeper is assured of an ample harvest. Later comes

*Calicotome villosa*, *Thymus Numadicus*, and other species of *Thymus*, several species of *Cistus*, and many other honey-yielding plants; so that, in fact, there is a good harvest from November till May, which is quite a long period, especially when we consider the great abundance of the honey-yielding flowers during the whole time.

It must be borne in mind that every pound of honey collected is so much clear gain to the national wealth of a country; for, if not collected by bees, the honey is absolutely wasted. Fruit-growers and owners of almond-orchards should remember, too, that greatly increased crops of fruit are obtained if there are ample bees kept to insure efficient fertilization of the flowers.

The bees of Tunis are very hardy, good workers, and are all that can be desired for the country, and I strongly recommend that the introduction of foreign bees be not attempted; and in view of the fact that the bees here, so far as I have seen, are free from the disease called foul brood (which has caused, and is still causing, such havoc with the bees of Europe), I advise that the most stringent measures be taken to absolutely prohibit the importation of any foreign bees, as the risk of the disease being introduced thereby would be very great (it being very widespread in Europe).

The Chalet, Welwyn, England.

#### WALKER'S GRADING-RULES CRITICISED.

The Rules too Flexible, and Why.

BY B. F. ONDERDONK.

*Friend Root*:—I have been reading Mr. Walker's grading-rules, and, after much thought and perplexity, have come to the conclusion that they do not grade. As I understand the word, "fancy" means appearing extra well. I fail to understand how a section with a row of unsealed cells next the wood can fill the requirement of "fancy," to say nothing about "extra fancy" allowing this defect; then his "fancy," "slightly fastened to or detached from the bottom," and "*two cells may contain bee-bread*" (italics mine). I grade his extra fancy for my own trade as No. 1; his fancy as No. 2, except as to the bee-bread, a section containing which I never offer for sale, but exclude it entirely from the grading.

Fancy, with me, must not have more than four unsealed cells on any one side of the comb, and unsoiled. No. 1 may have one row of cells next the wood unsealed. No. 2, one row of cells next the wood unsealed, and two or three rows at the bottom; no section to weigh less than 13 oz.; and very little amber honey in with white. No. 3, or fourth grade, may have two rows of unsealed cells, top and sides, bottom detached; and weight, 11 to 12 oz., goes to the peddler at 10 cts., regardless of color, comb, or honey. Lighter weights go back on the hives to finish if a flow is on, or clean out if bees need it.

Mr. Walker says, "No. 2 like No. 1, but

combs may be more crooked and uneven (*sic*), and not over three-fourths filled; but any one section must weigh half as much as the heaviest section in the case." To say nothing about his supplementary, which would allow his sections to be shoveled in, and modifies previous elastic rules, it looks to me like a barrel of unsorted apples, and I do not wonder at commission men's returns for consignments of honey if these rules obtain to any great extent.

Your grading is good, except fancy, which should not admit the whole row of cells next the wood unsealed. No. 3 should not go on the market. It hurts the business, and gives the retailer too much show to "do" the consumer.

I did intend my letter as an order; but the way things are looking now, I am not sure but I shall need a barrel of sugar instead.

Mountain View, N. J., Aug. 11.

#### APICULTURAL STATION OF THE MARYLAND AGRICULTURAL COLLEGE.

An Old Bee-keeper in Charge.

BY C. H. LAKE.

[A few weeks ago we received a letter from Mr. C. H. Lake in regard to an apiary that he had the pleasure of establishing at the Maryland Agricultural College and Experiment Station near Washington, D. C. At that time he promised to send us photos if we cared to have them. I told him to send them on and tell us something about the station and its plans. The photos are reproduced in half-tone on the opposite page. The station is located eight miles from Washington, on the Baltimore and Ohio Railroad, at College Park Station.—ED.]

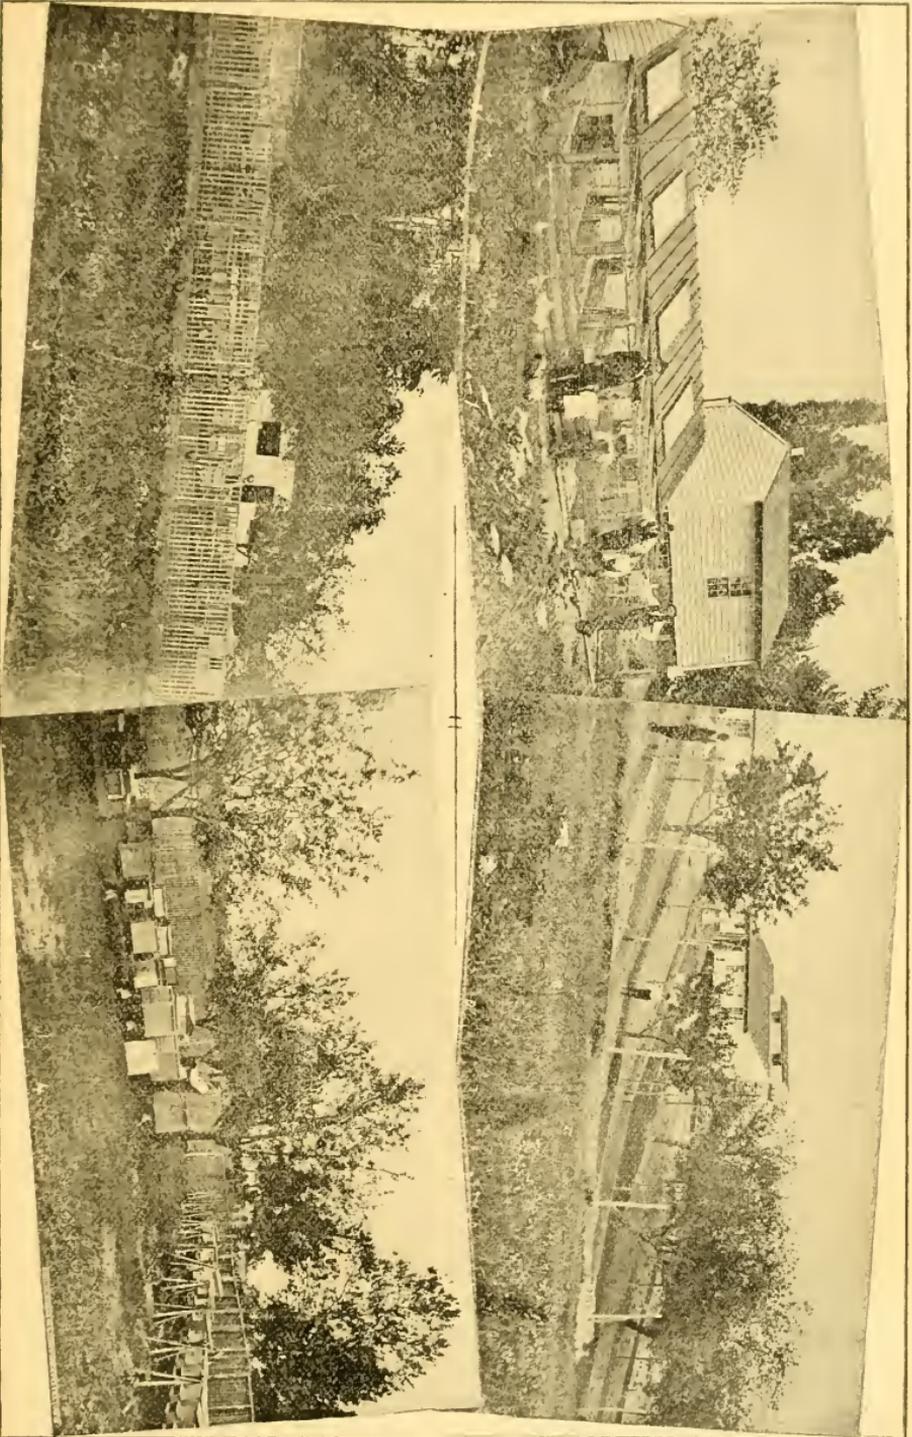

*Friend Root*:—I send you under separate cover the photographs of the aviary and apiary of the Maryland Agricultural College, and I will give you at this writing as brief a description as possible.

No. 1 is the brooder-house of the aviary; incubator capacity at present, 1300 eggs. The gentleman on the left is the president and his two children. Next is Mr. Taylor, the poultryman, and his little son. The other is intended for "yours truly." The trees showing over the brooder-house are on the rear grounds of the president's cottage.

No. 2 takes you a little farther up the hill. Place it at the *left* of No. 1 and you will see how the ground lies. It takes in a large part of the poultry plant.

No. 3 (again placed on the *left*) is the apiary, looking north. It is unfinished, as I wrote you; and, while it makes but a small show, it is more extensive than it looks. The white building is the honey-house and workshop. The window of workshop is nearly hidden by the tree. This view cuts off about 75 feet of the extreme left from view.

No. 4 is a view of this part taken from the shop-window looking south. So much for the views. Now take the plan. The long line of hives on the extreme left are all of the Baltimore pattern for extracting, and will contain 80 hives, to be covered in, for both shade and shelter. Along the front and poultry side, or at *a* and *b*, there will be located 100 or more

MARYLAND EXPERIMENT STATION: THE AVIARY AND THE APIARY.

comb-honey hives of the 8 and 10 frame Dove-tail patterns. This will leave the center grounds for nuclei, swarms, special hives, and test work.

What we propose to do, and how we shall go about it, I will not at this writing say; but the apiary is established, and your humble servant has been put at the head of both departments; and if I live I hope to see many a bee-crank (as well as poultry) who have been "over the ground" in the past.

Baltimore, Md.

-----  
 RIETSCHÉ AND FACTORY FOUNDATION COMPARED AGAIN.

Which is the Cheaper for the Poor Man to Buy?

BY F. L. THOMPSON.

*Mr. Editor*:—Inclosed find a sample of foundation made on a Rietsche press. It is part of a sample which came in a letter from Herr Rietsche himself. I had not intended to say much more on this subject; but on reflection I conclude it is too important to be allowed to drop in its present stage.

In his letter Herr Rietsche says that, given the ability (to work the machine, I suppose), his press turns out the exact thickness, and consequently strength, of foundation desired for use in the brood-nest. For example, the smallest size, which is 22 by 17 centimeters (8.66 x 6.69 in.), makes 36 sheets of a kilo of wax, corresponding to a square surface of 1.35 meters. The size for the normal German frame (22x35 centimeters, longer dimension vertical) makes 14 sheets to the kilo, or 1.1 square meters; a press 25 x 40 centimeters makes 9 or 10 sheets; or 9 to 1 meter; and so on, the larger the size the thicker the foundation, and conversely. Most bee-keepers, he says, are of the opinion that foundation should be no thinner than that proportion for the brood-chamber, and that, for the normal German frame, it is much better to make only 12 or 13 sheets to the kilo, instead of 14. Therefore, he concludes, home-made foundation is entirely fitted to the needs of the brood-nest, and makes the bee-keeper independent of the manufacturer, not to speak of the facts that he can use up his own pure wax, free from foul brood, and that he needs no artificial helps, such as wiring, etc., to get a beautiful comb built.

It appears from this, that, when one wants to wire his frames, he should specify the thinness of foundation he wants, as well as the size, in ordering; otherwise he will get a machine making foundation thick enough to dispense with wire. Perhaps this was the reason the circular that came with your machine claimed no more for it than a square meter of foundation to a kilo of wax.

For myself I prefer wiring, for several reasons, and am not suspicious of the purity or cleanness of the foundation furnished by our dealers. I favor the consideration of the Rietsche press only because it saves money and is easy to operate.

The sample inclosed is stated to have been made on a press which makes sheets measuring 25 x 20 centimeters; hence, if the above rule of proportionate thickness is exactly carried out I judge it is a trifle thicker than that made on the smallest press, which runs 1.35 meters to the kilo. Now, since the *vertical* height of a sheet made on the smallest press (evidently adapted to the standard "Halbrähmchen" or half-depth frame) is about 6 7/8 inches, while the L. sheet is 7 3/4 inches, the sample inclosed ought to represent about the thickness Herr Rietsche would consider suitable to the L. sheet, *without wiring*. In this country, however, we had better assume that full sheets would be wired. If so, we may also assume that the thickness of 1.35 meters to the kilo would be about right for the *wired* L. sheet. If I figure rightly this is about 7 1/4 sheets to the pound. Let us call it 7, and assume further that we can do as well as a ten-year-old boy at the Reichenberg convention, who, seeing the exhibition of foundation-making, asked permission to try the machine himself. His first sheet was a success, and he kept on the whole afternoon, employing "scarcely a minute" for each sheet. Then 7 lbs. an hour are worked, or \$1.12 an hour saved (if that weight of foundation, made on a mill, would cost 41 cents per lb. in quantity), or \$8.96 a day at the least, with the probability of at least doubling it—*for* Herr Rietsche is too well known in Germany to make it at all likely that he would make a statement of the speed of his machine that no one but himself could possibly attain.

I think something must have been decidedly wrong, either with the machine you tried or the way it was worked; for in all my reading of foreign journals I have not come across a single hint that foundation could not be made as thin as desired on a Rietsche press. This much seems certain, that it will not do for us Americans to be satisfied with our present knowledge of the Rietsche press. We must find out more about it before we drop the idea. If I could save \$1.12 to \$2.24 an hour, I should be quite willing that the bases of the cells should be considerably thicker than those in bought foundation; and, for that matter, is there any reason for supposing that they can not be made thin? Herr Alfonsus' statement, that foundation *can* be made as thin on the press as on the mill (on which I based my first assumptions) may be accurate when applied to the mill foundation that he has seen; and whatever thinness that may have had, is likely to be thin enough for the *bases* of the cells of *brood* foundation; while by altering the shape of the die surface (as was done in making rollers for the Given foundation), the amount of wax in the *walls* may give the required weight and strength to the foundation. However, this is all theory with me, and I ask, for information, what is the reason for assuming this can not be done in a molding-press? May not such an assumption be something like assuming that Given foundation could not be made on a roller mill?

Perhaps it is not altogether fanciful to suggest further that the introduction of an easy

and cheap method of making one's own brood foundation would result in a far more general use of foundation, with the attendant benefits, than is indicated even by the amount of money saved. That would be in accordance with human nature, at any rate. To pay out cash is much less likely to happen than to utilize what one has.

It strikes me that that "mussing-up of things generally" on page 446 is about as strong an expression as could be found to describe the molding process. True, I can't speak of it at first hand; but reading ought to give one a faint inkling of how matters are; and my reading so far has failed to show how there is any more mussing-up than in the inevitable task of melting up the wax product of the apiary; in fact, I should have inferred from my reading that it was, rather, a clean operation.

I note that you do not say that the majority of bee-keepers who have roller machines have long since come to the conclusion that it does not pay to make brood foundation for their own use. Perhaps they can't make it pay to make their own surplus foundation—a different matter. And even if they did make the statement of brood foundation, I should take the liberty to disagree with their assumption that their own circumstances are a rule for others. A man who can afford to lay out \$30 for a roller mill for his own use alone, with as little inducement as has hitherto been held out to do so, must for that very reason have some store of this world's goods. His interests are likely to be varied, and must be considerable; therefore his time must be worth, financially, a good deal more than mine. Most probably he *hives* help; and why should he not buy foundation? It amounts to the same thing as buying an expensive mill, and *hiring* a man to put his time in on the fuss and muss which it requires. But the poor man may have to lay out as much, or more, for foundation in any one year as a molding-press ought to cost him, while at the same time he gets no more for his time than a day laborer, counting the whole year. Why should he not get a cheap press, which, if we are to believe anything at all that is said of it, requires very much less fussy and mussy work than the mill? It is fallacious to refer to the experience of the majority of bee-keepers in this matter, for they have had experience with the mill only. So far from being less able to compete with the roller machines with the factories, there are the best of reasons for thinking it is better able to compete. A table-knife successfully competes with a razor in a good many ways. Let us not imply that it is absolutely essential to impart a factory gloss to a home-made article for home consumption.

Dr. Miller doesn't want the bother and worry of making his own foundation. I shouldn't either, if I had as many irons in the fire as he has. It is a wonder he wants the bother and worry of doing any thing with wax, or of keeping bees at all. Mr. Editor, I respectfully request that you put out of the room all those bee-keepers who are presidents and secretaries and factotums of this, that, and

the other organization, rose-fanciers, etc., and all those who have sixteen assistants to boss—unless they promise to be good, and imagine themselves in the place of the representative bee-keeper who depends on his own pair of hands alone to secure him a year's support for a year's work, and who fondly hopes that his rainy-day pile, repeatedly scattered and tramped on, may some day begin to grow again.

Montrose, Col.

[You admit you have never tried the Rietsche press; and that being the case you have to get your facts and figures second-hand. Granting, for instance, that we are prejudiced in favor of factory-made foundation, it is reasonable to assume that the inventor or manufacturer of the Rietsche press is equally prejudiced in favor of his machine; but, so far as possible, let us eliminate prejudice, if there be any, and let cold figures speak for themselves.

In the first place, your figures—at least some of them—are incorrectly drawn. You are assuming that the sample of foundation you sent to us runs about  $7\frac{1}{4}$  sheets to the L. frame. I carefully weighed it on delicate scales, and found it ran about 6 L. sheets to the pound. To prove the result, I went down into our wax-working department and picked out 6 sheets of medium brood foundation which ought to weigh 6 L. sheets to the pound. These, when placed on the scales, responded to the proper notch. Out of one of these sheets, all run at the same time, probably within a minute of each other, I cut a square of foundation equal in size to the little sample you sent. I then took a pair of delicate watchmaker's balances, and, having found that they "balanced," I placed a piece of Rietsche foundation on one side and a piece of our medium brood on the other side, both of exactly the same size. They balanced exactly.

Again, I notice that you figure wax at 25 cts. a pound. This figure does not include the cost of refining and a slight loss from dirt. After being cleaned it is worth 5 cents more. This would make the wax run 30 cents a pound in place of 25; for the 25-cent article will be hardly fit—at least the average run of it—to make decent foundation.

Then you have made another error in putting the price of factory-made foundation at 41 when it should be 40. Assuming that your boy or man on the Rietsche press would make 50 pounds of foundation in a day (which I very much doubt), you ought to take the 50-pound rate for factory-made foundation. Now, then, let us start over again:

I noticed you have allowed the boy or man 49 sheets per hour on the Rietsche press, on the basis of 7 sheets to the L. frame; but if you figure that the Rietsche sheets are only 6 to the pound, as per sample, then we will give you credit for 8 lbs. per hour, which at 30 cents would make a total of \$2.40. Suppose the poor man's time is worth 15 cts. an hour, this would make a total of \$2.55, not allowing any thing for express charges on machine from Germany, cost of the machine itself, the mussing-up of pots, kettles, and

pans, and the probable scorching and spoiling of some wax—a result that is quite liable to take place with the ordinary amateur. Medium brood factory-made foundation in lots of 50 pounds would cost \$3.20, leaving a balance in your favor of 65 cents—that is, providing we do not figure in the cost of the Rietsche press, express on the same, mus.ing up, soiling of pots and kettles, and the possibility of ruining some wax.

If you have saved 65 cents, you have a proportionately inferior article of foundation. It is clumsy and brittle, as is all cast wax. Careful examination of the sample foundation you sent shows that there is a fearful waste of wax in the bases, and not enough side-wall to make the bees take it quickly. That being the case, it is very evident that light brood foundation, factory-made, would not only be just as good but just as cheap—yes, far cheaper—if we include the incidental items referred to. Forty-nine sheets of the latter will cost about \$2.57, and the foundation that you made would cost \$2.55.

I carefully tested, by heat, factory-made light brood and the Rietsche sample sent, and found that the former was not only tougher, but could resist heat fully as well.

To argue that a bee-keeper can afford to make his own foundation would be like trying to prove that a small flour-mill could compete with one of the great establishments of the country, or that the old-fashioned cobbler could make a pair of shoes as cheaply as the great shoe-factories. You may be able to so place the figures as to make a strong case; but you can not get around the fact that even the small manufacturers of foundation have generally given up the trade to the large manufacturers, for the reason that they can buy cheaper than they can make it. What is true of the small manufacturers would be more true of the consumer.

I am not trying to show that bee-keepers ought to buy Root's, Dadant's, or the foundation of anybody else, rather than to make it, for the sake of bolstering up the supply business; but I do think it would be about as foolish for one to make his own foundation as for him to try to make his own clothes. There has been a great deal of money wasted by a good many people trying to make their own things "to save manufacturers' profits," instead of sending to the factory and getting something much better, and usually for less money. Some bee-keepers even now are foolish enough to try to make their own hives and brood-frames. If they will be careful enough to figure, they would see that they are probably paying as much for their lumber to make a certain number of hives as they would have to pay for the same lumber at the hive-factory, all neatly and accurately cut up, and ready to nail together.

I wish I could say these things in some other journal than our own; for as it is, at least some will shake their heads and say, "He has got an ax to grind." Perhaps some of our readers will think I am taking a good deal of space for either side of this question; but GLEANINGS believes in free speech, and

in letting both sides have a hearing up to a reasonable limit.

#### MIGRATORY BEE-KEEPING IN CALIFORNIA.

Some of the Difficulties; Large and Small Wagons for the Purpose.

BY C. A. HATCH.

To one living in the East it seems marvelous and all sunshine and pleasantness when he reads of the great yields of honey in this country. But California bee-keeping has its drawbacks as well as any other country. The first thing noticeable to a new comer is the fact that scarcely any bee-keeper lives where he keeps his bees. This of itself makes the bee-man at least migratory, even if his bees are not. The reason for this is that few of the good honey-yielding plants grow on land suitable for farming, and usually of no great value except for stock-ranges; and, further, while California produces many honey-plants, there are but few locations where more than one are available; therefore the successful bee-man must be prepared to emigrate to pastures new when one place has been worked; and when a dry season comes he must be ready to take advantage of any chance honey-flow he may hear of.

My experience has been confined to the Santa Clara Valley. Here we find most of the bee-keepers live in the towns, and move from place to place, sometimes going as far as 100 miles from home. Many are single men with no families, and camp anywhere during the bee-season. Some go to the mountains during the sage-bloom, and then either move to the coast to the bean-fields, where lima beans are grown by the thousand acres, or go still further away from the coast to get California buckwheat or buckbush honey, which is a white fine honey, and nothing like our eastern buckwheat.

The kind of wagon usually used is a common farm wagon or a large freight-wagon needing four to six horses to draw it. M. H. Menzieson, who moves more than any other bee-man I know of, has built special racks for the purpose, suited to large wagons and large teams; but either small wagons or large ones are open to objections. It takes too long to move with two-horse teams, and the large wagons are too unwieldy with their long string of horses to go every place that it may be required to go to. Most of the apiaries are in the parts of the country where roads are not of the best, and there are always many risks by rocks, floods, quicksands, etc.

The bees are prepared for moving, first, by extracting all from the supers if run for extracting; or, if for comb, all supers are removed, and each hive must have not less than four empty frames in the brood-nest, and, if moved at the close of sage-bloom, an empty extracting-super having alternate empty combs and empty frames is put on. Second, the entrance is closed with a screen, and a frame covering the whole top of the hive, covered with wire screen, is put on. This screen cover

has the two end pieces made  $\frac{1}{2}$  inch wider, so that, when the hive-cover is nailed on, it leaves  $\frac{1}{2}$  inch space between the screen and hive-cover, so in case one hive is set on top of another, ventilation will not be cut off.

The hives are usually loaded at night, and the teams lie up during the day if the journey is to be too long for one night.

This is M. H. Mendleson's plan, and I think he has made the subject a study, and has the best moving-appliances I have seen, and makes a success of it where the distance is not too great for one night's journey. But I am inclined to think that, where the trip is too far for that, the present arrangements are inadequate. Too many colonies crowd the entrance full of bees, and thus cut off upward draft, which smothers too many bees — not that Mr. M.'s loss of colonies has been great (only about 10 out of 400 moved), but the weakening of colonies has been too great to leave them strong enough for good work until more bees are hatched, and then it is too late for the honey-flow. There seems to be greater loss than would appear by simply looking at the dead bees at the entrance, so I came to the conclusion that many that apparently came through all right were so weakened by worry that they soon succumbed when put to work.

There seems to be another difficulty in the way of migratory bee-keeping being a brilliant success; and that is the fact that colonies at the close of a long and abundant honey-flow are not as strong in numbers as at the beginning. Of course, this can in a measure be overcome by giving particular attention to breeding bees during the honey-flow. Good ventilation and a circulation through the hive are essentials. In two instances have I known of disaster for lack of these two essentials. One man lost a third, and the other much more. This was loss outright, to say nothing of injury to others.

I rented bees this season, first, because I was a "tenderfoot," and did not know how much my Wisconsin bee-keeping would avail me here; and, second, because I wanted to be free to go when the honey season was done. I ran one apiary for Mr. Mendleson, consisting of 233, spring count, and 275 at the close of the season. From these we extracted 48,500 lbs., and then removed to the bean-fields, where the prospect is fair for getting 4000 lbs. more.

Bean honey is fine-flavored and white, but inclined to candy quickly.

Montalvo, Cal., Aug. 10.

#### AMONG THE BEE-KEEPERS OF MICHIGAN.

The Advantage in the Use of Bottom-starters; Developing the Home Market; Hives for Migratory Bee-keeping.

BY A. L. BOYDEN.

Reaching my old home at Saline for a few days' vacation I found that the season there (Southern Michigan) had been better than for a number of years past. White clover, which had almost disappeared, has returned,

and a fair crop of honey had been secured. Looking over the cases of comb honey I had to compliment my brother on the appearance of it, as the combs were built down so well, and so securely fastened to the bottom. He had used bottom starters, and declared himself very much in favor of them. I believe that much of the breakage in shipping might be avoided if combs were well built to the bottom of the section; and perhaps the best if not the only way to secure this is by using bottom starters.

A day or two later we had a very pleasant call from Mr. W. D. Simonds, of Whittaker, Mich. Mr. Simonds formerly used chaff hives, I believe; but, being annoyed with foul brood, and for other reasons, he has given up their use, and now uses a house-apiary. He is very enthusiastic over it, believing that, for ease in handling, freedom from robbers, and safety in wintering, it is all that can be desired. I believe he mentioned only one difficulty; viz., an occasional loss of queens in mating.

Saturday, Aug. 7, found me at the home and apiary of a Lenawee County bee-keeper, Mr. A. Middlebrook. He reports a fair season, showing me a nice lot of choice extracted and comb honey. I asked him where he sold his honey, and he replied, "In the home market." I then asked him what price his extracted netted him. He said, "About ten cents per pound." It seems to me that bee-keepers make a great mistake in not doing more to work up their home markets. Mr. Middlebrook has used frames about 10 x 14; but having tried the self-spacing Hoffman, he proposes to adopt this style in regular L. size.

#### IN THE WILLOW-HERB DISTRICT.

Leaving Washtenaw Co. for a few days' visit to Central Michigan I stopped first at Mount Pleasant. This is a pleasant little town in fact as well as in name. I had heard that the willow-herb never fails to yield honey, so I expected to find the bee-keepers of that section in the midst of the flow. Very unexpectedly, however, and almost unaccountably, it is yielding but little this year, and in some cases the bees were robbing. I called to see Mr. T. J. Fordyce, a supply-dealer who has quite a large apiary within the limits of Mount Pleasant. He was away from home, so I chatted with Mrs. Fordyce for an hour or more, learning much of interest to me about the willow-herb country. A puncture in my bicycle-tire delayed my departure for the out-of-town apiaries, so I passed the time very pleasantly with Mr. Wm. Bamber, proprietor of a planing-mill. He also keeps a few bees, and is making some supplies. Evidently the Dove-tailed hive is as popular there as elsewhere, as I noticed with interest a machine he had made for dovetailing them.

After dinner I started on my wheel for the apiaries of H. S. Wheeler, Walter Wing, and H. S. Morrison, which are located down the Chippewa River in the tracts burned over by forest-fires three years ago. I found neither Mr. Wheeler nor Mr. Wing at home, so I pushed on over sandy roads to Mr. Morrison's

yard. I might mention that none of these apiaries are located at the owners' homes. Mr. Morrison has about 200 colonies, and he uses largely the Simplicity hive. I spent the night with him, and very much enjoyed hearing him relate some of the incidents connected with his work in the willow-herb section. I had always supposed that, in moving an apiary to catch a honey-flow, a good deal of time would be lost by the bees, even after reaching the new field; but when Mr. Morrison told me he found bees coming back loaded with honey in *seventeen minutes* after the entrance was opened on the new field, I thought very differently. Indeed, I believe now more than ever that it will pay bee-keepers to use such hives as can be readily moved from one place to another without loss of time, and with no annoyance to the bees or apiarist.

[Mr. Boyden, the writer of the foregoing, is Mr. Calvert's right-hand man and stenographer. It was Mr. Boyden who, during Mr. Calvert's absence for nearly a month, assumed much of the work that devolves on my brother (-in-law) John. Before coming here he was engaged in the supply business in Michigan, and had quite an extended experience as a bee-keeper. He is now one of the old standbys of the office. In our next issue Mr. Boyden will relate something further in regard to his trip.—Ed.]

---

#### NOTES BY THE WAY.

BY J. T. CALVERT.

After leaving Reno we ascended the Sierras to the summit, 7017 feet above the sea, and above the snow-line, even in July. The descent into the beautiful State of California was a panorama of ever-increasing beauty. At Auburn we were greeted by the Christian Endeavorers, and treated to a bouquet of flowers for every one. Fruit was abundant and luscious, and cheap. When passing through Clipper Gap I learned that S. F. Woodworth, who has been making bee-supplies and fruit-boxes at that place, had recently been burned out—a total loss and no insurance. If your property is not insured, see that you have it done before you are a day older.

The C. E. convention was one of unusual interest and power. It has received such full notice throughout the religious and secular press that I will not attempt a report here. I set out to make notes of special interest to bee-keepers, and hope I may not entirely fail to do so.

I called on W. A. Pryal, of Oakland, who is still interested in bees. He had had the pleasure, a few weeks previously, of showing about the city Mr. Thos. Wm. Cowan, editor of the *British Bee Journal*. Mr. Cowan has a son in California, with whom he and Mrs. Cowan have been spending the past winter. They are so well pleased with California that they expect to remain another year and enjoy its delightful climate and beautiful scenery and abundant natural resources.

The great wheat-harvesters of California were a sight worth mentioning. These machines, drawn by 24 to 30 horses or mules, and cutting a swath 18 to 24 feet wide, cut the grain off just low enough to secure all the heads. The grain is thrashed, and put into sacks. The chaff and straw are either dropped in a swath, or, if it is desired to stack and use it, it is collected and dropped off in bundles, forming a winrow ready to be gathered and stacked. The grain, cleaned ready for market, is dumped off two or three sacks at a time, gathered up on wagons, and corded up in the fields. There are no barns or granaries, every thing being left in the open air. As no rain falls except during a few winter months, there is no need of the protection required in other sections of the country. Single fields cover hundreds and sometimes thousands of acres. I was told that they usually get two crops of wheat each year. The second crop is self-seeded from the first, and is usually much lighter. As I passed down the San Joaquin Valley much of the crop was already harvested. The immense wheat-storeshouses at the stations along the way were nearly full. Thousands of sacks were corded up in the fields. Other fields were not yet harvested, and, as far as the eye could see on either side the track, there was little to be seen but wheat-fields. As I looked on this immense stock of golden grain, and noted that the market price was advancing, I concluded that here were gold-fields of more value than those of Alaska, and that they would feed more people, and bring more blessing to mankind.

I stopped a few hours with M. R. Madary, of Fresno, who handles most of the bee-supply trade of the San Joaquin valley. He reported that, up to about the 10th of July, the bees had barely made a living, and bee-keepers had begun to feel rather blue. But at the time I was there, July 14, they were rolling in the honey at a very lively rate, and prospects were favorable for a fairly good crop. The main dependence here is alfalfa, and a very good quality of honey is produced. A cool backward season seemed to be the cause of a lack of honey earlier.

My next stop was at Los Angeles, where I spent several days. On the way there, near Acton and Newhall we passed apiaries near the railroad. From the looks of the mountains and country generally, at this season, as we passed along down the canyon, we wondered where the bees got so much beautiful honey as has been gathered in this section this year. The latter rains did not come, hence the honey-harvest was cut off earlier than it is when they have an ideal season. The sagebrush and other shrubs that produce honey were pretty well dried up at this time of year.

I found John H. Martin (the Rambler) at the office of the California Bee-keepers' Exchange, 330 South Broadway. He had had previous notice of my coming, and had notified a few of the bee-keepers near the city. In a little while Mr. Bennett, of the *Pacific Bee Journal*, dropped in; also Geo. W. Brodbeck. Soon half a dozen of us were together having a little bee convention all to ourselves. The

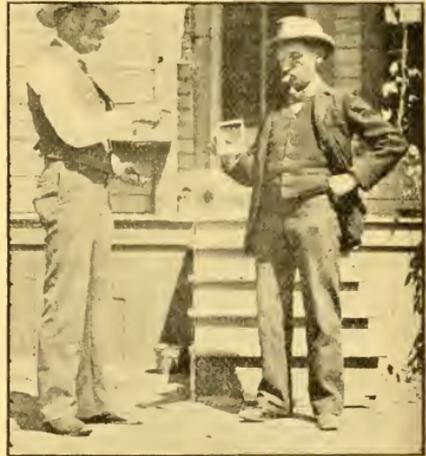

bee-keepers of Southern California were feeling quite comfortable from the fact that they had secured what they considered about half a crop. This half-crop was estimated to be from 250 to 300 carloads (12 tons to a car). Some commission men had reported to me that the crop would be 500 carloads; but Mr. Martin, who is secretary of the Bee-keepers' Exchange, and in a position to know, said that half that amount would be a fair estimate. San Diego Co. alone produced about 60 carloads, or one-fifth to one-fourth of the whole. Quite a number of cars of honey had already been sent east, and some to Europe, by the commission men. The Bee-keepers' Exchange had employed the Cutting Fruit Co. as their selling agents, and also fixed upon the minimum price for the different grades; and up to the time I was there (July 20) had made almost no sales. They had already warehoused quite a little, advancing to the bee-keepers about half its value until it should be sold. Some bee-keepers, who were anxious to get their money, were selling outright to dealers and commission men at lower prices than those fixed by the Exchange. It will take some time to clean up such lots of honey, when the Exchange may hope to realize on their honey. It will take patience and perseverance on the part of the members of the Exchange till they become established. Some changes in methods of management may be found necessary; but there is no question that they are on the right track, and that, if California bee-keepers generally stand by the Exchange, they will be benefited in no small degree. Exchange honey is sold under a trade-mark seal, and guaranteed.

Perhaps nine-tenths of the honey produced in Southern California is extracted. The proportion of comb honey, however, is increasing, and it would be hard to surpass anywhere some of the comb honey I saw.

One of the leading bee-keepers is M. H. Mendleson, of Piru City. He has 900 colonies of bees, and up to the middle of July had taken over fifty tons. He had just moved his bees to the bean-fields, where he hoped to secure 12 to 15 tons more. If it were not for the faithlessness of a tramp bee-keeper whom he had engaged for the season he would have had at least ten tons more. This man, a Mr. Frank Curl, has lots of ability and a great deal of experience, and can make himself very useful. He has wandered about so much, having been in almost every State in the Union, and to Cuba twice, that he can not control his wandering mania. He has been here in Medina three times in the last twelve years. He engaged to Mr. Mendleson for the season, and left him just when the honey was coming in fastest and he could least afford to spare him. He even offered him double the wages he had agreed to work for; but nothing would induce him to stay. I mention this here that others may be warned.

Mr. Mendleson put into use this season 30 of the Danzenbaker hives complete, and 500 of the Danz. supers, which he used over the regular 10-frame L. hive. He had 30,000 of the Danz. sections filled, and most likely

would have had forty to fifty thousand had not Mr. Curl failed him at the critical time. While he does not like the brood-chamber of the Danz. hive, he is much pleased with the super, and expects to get as many more for next season. The honey he produced in the Danz. sections, put up in our basswood cases, nicely labeled, was handsome indeed. He was getting 11½¢ per pound from the fancy grocery trade, while large lots in the regular 4¼ sections and pine cases made on the coast were bringing 8 to 9 cents.

RAMBLER AND MENDESLESON DISCUSSING THE DANZENBAKER SECTION.

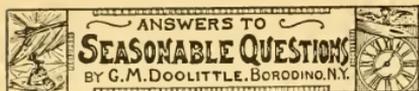

While in Los Angeles I enjoyed the hospitality of Rambler's "bachelor hall," and partook of the pancakes for which he is deservedly famous. We had Mr. Mendleson with us a part of the time, and I am pleased to be able to give you a view of "the other two," with a rear view of the "hall" in the background.

Some C. E. ladies from the East called on Mr. Martin after I left, and he writes me that he could not prevail on one of them to remain in Southern California.

Although I visited the State at the worst time to see it at its best, I was delighted with it, and hope to go again before many years roll by, and stay longer.

---

THE editor of the *Review*, in speaking of the passage at arms between Mr. Newman on the one side, and Messrs. Mason, York, *et al.*, on the other, says he can not close without "expressing regret at the spirit exhibited by Mr. Newman toward some of his old friends who have thought his course open to criticism." That is the way a great many more of Mr. Newman's old friends feel about it. Not one has had a desire to accuse him of being "dishonest," neither have they felt "malignant" or "spiteful" toward him.

#### LONG HIVES VS. TIERING UP.

*Question.*—Why do not those working for extracted honey use a long hive, holding the same number of frames that they wish to use in one story, instead of tiering up several hives, one on top of the other, as is advised in our bee-papers, and quite generally practiced? I am of the opinion that a long hive would be more convenient, and that less time would be consumed in the manipulation of it.

*Answer.*—The above brings to my mind what happened years ago; and as it will serve to answer the correspondent's question I will speak of it here.

Some twenty or twenty-five years ago Mr. D. L. Adair, of Kentucky, was quite a prominent bee-keeper and writer for our bee-papers. He used and advocated a long hive, to be used on the principle of spreading frames out horizontally, instead of tiering one hive above the other, claiming that, thereby, a colony of bees could be kept in a normal condition, and while in said condition no swarming would be the result. This he termed the "Long-idea" hive. Being always ready to test all "new ideas," I made two hives, each four feet long, during the next winter. One of these I worked for extracted, and the other for comb honey, on the Adair plan. The one worked for comb honey swarmed, either because the "idea" was faulty, or because I did not know how to fully manage such a hive, or both; so after repeated trials to keep them at work in the four-foot hive I let them have their own way, when they had swarmed after being returned the fourth time.

The one worked for extracted honey did splendidly; but another, worked on the tiering-up plan, did nearly or quite as well; and by practical knowledge I learned that I could work a two or three story hive much more easily than I could this long one. To take the frames out, the person's back must be bent just enough to make it the hardest kind of work; and the bees which were shaken off the combs would crawl all over the sides and top of the hive in such numbers as to make it almost impossible to close it again without taking much valuable time. With the two-story hive the bees could be shaken on top of the frames in the lower hive, with but very few taking wing, when they would crawl below till the hive was closed; and the operator could stand erect, or nearly so, while doing the work.

But the worst thing about it was that I lost both colonies during the next winter, and during every succeeding winter that I tried to winter bees in them. So far as I could see they were prepared for winter as well as any of the other hives which came through the winter in good condition. I tried these hives for honey several years, putting colonies from

other hives in them in the spring, as often as those in them died, but with no better success than at first; and finally, becoming disgusted with them, I tore them to pieces and made the lumber into other hives. For extracted honey, I know of nothing better than using any of the ordinary hives two and three stories high, according to the populousness of the colony being worked.

#### ITALIAN BEES NOT WORKING IN SECTIONS.

*Question.*—I have had Italian bees for the past two seasons, and they have made no surplus honey, while from my blacks I have had fair returns in section honey. What do you suppose is the cause of this? and what course shall I pursue to remedy the matter?

*Answer.*—As the writer does not give information as to the number of colonies he keeps, it is hardly possible to tell just what course should be pursued in the matter. If he has ten or more colonies that persist in not entering the sections, it is something I never knew of happening before; but if there is only one or two colonies which act that way it would not be very strange. One important point in the construction of a hive for comb honey where Italian bees are used should not be overlooked; and that is, the brood-chamber should not be too large. If the questioner has a brood-chamber of from 2500 to 3000 cubic inches, I should not wonder at the actions of the Italian bees; for Italians are more prone to store honey in the brood-chamber than the blacks. Especially do they show a preference toward storing in the brood-combs over the sections if the queen does not have the combs occupied with brood when the honey season commences; and if they have room to store from 30 to 40 pounds of honey in the combs below they will very likely not go into the sections at all. If bees refuse to work in sections, there are various methods of coaxing them to go to work. I will give two or three which are usually successful.

If a section, or several of them, are taken from a hive where the bees are at work nicely in them, and placed on the hive where the bees are loath to enter the sections, carrying the bees that adhere to the sections with them, it will usually incite the non-working colony to go to work in the sections also. If this does not work, fit a piece of drone comb, containing small larvæ, into one or two sections, when the bees will at once commence to work in the surrounding sections. Or you can drum or shake from the frames the larger part of the bees and the queen from such colony as will not work in sections, and put them into an empty box or hive; and when they get to building comb nicely, put them back where they came from. Where this plan has been used I never knew them to fail to work, going right to the sections, and building comb in short order. In drumming out the bees, do not drive too close, as bees enough must be left to fully protect the brood. The nice white comb that the drummed colony build while in the box should be placed in the sections for "baits," for there is no greater incentive to commence work than new white

comb containing a little new honey. Of course, all of this is given on the supposition that our questioner's bees were strong enough as to numbers to work in sections, and still refused to do so, when the honey harvest was on. Where any hive is not filled with bees it is useless to attempt to make them work in sections. Many are deceived in this way, and I mistrust that this has something to do with our friend's bees not working. Italian bees do not breed quite as rapidly early in the season as do black bees; but if attended to as they should be they will have more brood in just the right time to give us laborers in our field just when we wish them than will the others. That Italian bees are inferior to black bees for comb honey, if properly managed, I never could see, even in a good season; which fact is now generally conceded by nearly all of our best bee-keepers; while in a poor season they certainly show great superiority over the latter to the amount of quite a surplus, while the black bees scarcely make a living.

in my chicken-yard, under a large apple-tree which furnishes shade for both chickens and bees all day except in the early part of the morning. The yard is 30 by 40 feet, inclosed with wire netting 7 feet high, in which I keep eight Black Minorca hens. These keep the grass and weeds down so that you could hardly find a blade of grass in the whole yard. The chickens and bees run a separate business, and never interfere with each other except when I shave off the heads of drones, and the bees carry them out. Then the chickens will clean them up.

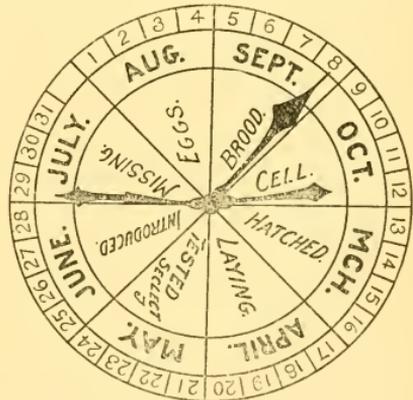

I had ten stands of bees; increased to 21, and got nearly 900 lbs. of comb honey, which I think is pretty good, considering I live in a city, and do not follow it for a business. One advantage, I think, in having a high fence around your apiary is that it compels the bees to fly high enough to get over, and keeps them out of the way of any one who may be in another part of the yard.

L. I. SHRADER.

New Albany, Ind., Aug. 5.

A QUEEN-REGISTER DESIGN.

Inclosed find a queen-register card that I use for keeping record of hives, in which I am raising queens. I have 30 hives of blacks in my apiary, and wanted to raise Italians for

HILTON IN FAVOR OF THE SQUARE BOTTOM-BARS.

I have just read O. O. Poppleton's article on page 517, and it has given me courage to say I was much pleased with the  $\frac{3}{8}$  bottom-bars and so sorry when you stopped making them; and many of my customers have asked for those "square bottom-bars." I have been tempted several times to ask you if you could not make mine that way, but would think I ought to conform to the will of the majority. But I feel with you that the majority does not know what is wanted. I never had so many frames fastened to the bottom-bars as while using the  $\frac{3}{8}$  bottom-bar. I hope you will make more of them, and always send me that kind.

GEO. E. HILTON.

Fremont, Mich., July 19.

[I have noticed that all the square bars in our apiary have the combs built clear down to them, and most of them are solid slabs without a place for the queen to hide. The only objection to them is that the bees will not only build down to them, but sometimes clear past them, on to the next set of frames below. This was urged at the time we made the change, and was considered so serious that the substitution for a wider bar seemed almost imperative.—Ed.]

ANOTHER WAY TO KEEP GRASS DOWN IN THE APIARY.

After reading what you had to say in the last number of GLEANINGS about sheep keeping down the grass in the apiary, I thought perhaps my way of doing it would be interesting to you and your readers. I keep my bees

each hive. I tack this card to a  $4 \times 4 \frac{1}{2}$  piece of pine, then drive one tack through the hands or registers. I then drive in four tacks with the heads  $\frac{1}{4}$  inch out; then I turn the board card down. All I have to do to know the condition of a hive is to turn over and look. This was my first attempt at queen-rearing, and I must say I enjoy it. I am trying to follow instructions as given in the A B C of Bee Culture.

R. S. WILSON.

The Gums, Miss.

HONEY-FLOW PHENOMENAL.

The honey-flow is over in this locality, and all I can say is it was phenomenal. I have never seen the clover bloom as early and last as long as it did this year. We had a fair fruit-bloom, a very light locust, and a very light basswood, as a great many of the few

trees of that variety we have in this section failed to bloom. I had only 9 hives, spring count; now I have 32; have taken off 300 lbs., and have 700 or 800 more to take off. I have sold 250 lbs. at 20 cts. per lb. The clover honey is as fine as silk and as white as foam. The fruit-bloom is rather dark, but of extra flavor.

J. L. BELL.

West Middletown, Pa., July 27.

MARKETS SMASHED; TOO MUCH HONEY; FOUL BROOD AND POOR SEASONS BLESSINGS IN DISGUISE.

Our white-honey harvest is not over; bees are working hard on both white and sweet clover. I never saw in Wisconsin such solid fields of white clover as we have had, and it keeps renewing right along. Weather is now splendid for secretion.

Our local market is smashed. I sold a few crates to merchants in Monroe at 12½; then in came the farmers and filled them up at 10 cts. Now the farmers are going to everybody and selling at 10 cts. Merchants expect to buy at 8 cts. (fancy comb honey). I have sent some trial shipments to Chicago and Milwaukee, but have not received returns yet. N. E. France writes me that those markets are already filled up with California honey, both comb and extracted. It looks to me as though the business has fallen by its own weight, and foul brood and bad seasons have been friends instead of enemies. I had expected to go more largely into honey production, and am running now about 160 colonies; but your kind advice (which I was wise enough to heed), not to give up railroad work, was the best thing for me that you could have advised. I have had three months' leave of absence this summer, and have worked hard in the apiaries here and at Monroe, and had a good man helping me. The Monroe field is a splendid one, and a nice place to live. Brown-town promises to give a heavy crop from the large branching sunflower again this year.

HARRY LATHROP.

Browntown, Wis., July 29.

R. H. L., O.—Sometimes a swarm will come out and enter into another hive, the result being a battle between two lots of bees. Instead of allowing them to fight, however, you should have smoked them both thoroughly.

I. M., Mich.—I feel quite certain that the bees in question have been visiting milkweed, for I notice the milkweed-pollen appendages to their legs. I think you will find the milkweed is in bloom in your vicinity, and that the bees are working on it. The reason why you think they are robbers is because, when they go into the hive, the other bees attempt

to claw off the appendages, and they are apparently attacking them as if they were robbers. For fuller particulars we would refer you to "Milkweed," in the A B C of Bee Culture.

R. C., Neb.—There must be some mistake about the rumor that you heard regarding a bee-keeper in Illinois feeding his bees glucose by simply knocking in the head of the barrel containing the stuff, and letting the bees help themselves. Bees will not touch clear glucose unless it is diluted; and even then they will not touch the stuff that is ordinarily used for adulterating. It is too vile, and has too small an amount of sweet to attract their attention. It is possible, however, that the party you refer to buys grape sugar, often called glucose. This is not a bad sweet. Years ago, when sugar was much higher than now, we used to feed our bees this kind of sugar to stimulate brood-rearing. It is such a mild sweet that the bees would never rob. It does not pay to use it now.

J. H. McC., Ark.—We can not explain why your bees should swarm more this year than usual, unless it is because the honey-flow has been unprecedentedly heavy. It does not do to return a swarm back to the hive from which it came, without changing its internal condition. They will sulk, hang out, loaf, and finally swarm again; in fact, they will swarm as often as you hive them, and as long as the honey season continues. The best way is to hive them on the *old stand* on starters or frames of foundation in another hive. The old parent colony, while the swarm is in the air, should be removed to another location. If there was already a super on the parent colony, it should be put on the new hive now on the old stand. For particulars, see page 32 of our catalog; also our A B C of Bee Culture.

W. W. P., Ill.—It is not difficult to understand why you lost your queen. You probably failed to note carefully the first three sentences of the directions for introducing. We have sent you another set of directions, and now call your attention to the fact that a colony that has been queenless from 12 to 15 days is not likely to accept a queen; for in that time they are pretty sure to have a substitute of their own, in which case it would be simply impossible to introduce a queen. We never think of trying to introduce where we find a number of queen-cells. You may be sure you have destroyed them all; but even if you do succeed, the bees somehow have the *impression* that they have cells, and that, consequently, they are going to have young queens, and they do not want an introduced mother. You will note that the directions state that colonies should not be queenless over five days, and two days are usually better. The reason for this is that in this short length of time the bees have not had time enough to rear cells, or, at least, sufficiently far along to "bank" on future prospects. The directions that we have prepared for introducing queens have been adopted by all queen-breeders; and from this it is reasonably certain that the statements contained there are very nearly correct.

MR. HUTCHINSON says, "Starting a journal simply to enable one to berate some one, is too much like biting off one's nose to spite his face." Just so. The experiment has been tried two or three times, and the result has been just as Mr. H. says.

PROPOLIS is now getting to be a little stiff and hard, and it is sometimes a difficult matter to separate the super from the hive-body. Nothing is better for this purpose than a large screwdriver. Better yet, don't leave supers on too long unless you are after an extra quality of well-ripened honey.

DID you ever notice that the strong, smarty flavors of some honeys are rendered much more mild if eaten with bread and butter? After all, almost any honey tastes better when taken in connection with the staff of life. I remember that once the judges of a honey exhibit at the Ohio State Fair insisted on having bread and butter to test the honey by.

MR. HUTCHINSON, in commenting on the fact that Mr. Vernon Burt keeps grass down in his apiary by letting sheep run among the hives, says the only objection he can see to it is that the "ground might not be so tidy as we should like it;" and while he admits that it is considerable work to keep grass down with a lawn-mower, he is of the opinion that the accompanying advantages arising from the use of the mower are worth all they cost. I can readily see how Mr. Hutchinson would think the ground might be untidy in places where sheep were kept; but if he could see Mr. Burt's apiary I think he would conclude with me that the ground about the hives is as neat and clean as a mower could make it.

At our house we like well-ripened honey—honey that has been on the hive for some two months after it has been stored and sealed. We have some supers at our out-yard, containing sections of sealed honey that had been on the hive for some six weeks after being capped over. The cappings are badly travel-stained, and sections pretty well smeared with propolis; but the eating of the honey is where the best part comes in. Such travel-stained sections would not sell; but for my own use I prefer them every time. I do not know that I have any particular liking for propolis and travel-stain, but I do like honey that has been ripened by the bees.

A SUBSCRIBER sends us a section honey-box which he says is over thirty years old. It is exactly  $4\frac{1}{4}$  inches square, and the thickness of the stuff itself is  $\frac{3}{4}$ . Our subscriber does not give his name, but says, "Contrast this with the Root sections of to-day." The re-

markable thing is that it should be  $4\frac{1}{4}$  square, exactly the size of the standard section of to-day. It was A. I. Root, I believe, who fixed the standard size of the sectional honey-box, and that was away back in 1872, I think. That would be only 25 years ago. A. I. R. adopted the  $4\frac{1}{4}$  size because 8 of them would just go inside of an L. frame. It is possible that the user or maker of this section adopted the same dimensions for the same reason.

In a recent editorial, in speaking of the fact of our now using new type and a new press to get out this journal, I wound up by saying that, while we did not claim to have the best bee-journal, we did think we were "keeping up with the procession." To this claim the editors of both the *American Bee Journal* and the *Bee-keepers' Review* have kindly given their cordial assent. The fact is, I could not honestly say more, knowing the general excellence of our two rival cotemporaries.

By the way, how much better it is to be modest and moderate in statement regarding one's own wares, one's own journal, or one's own baby, if you please! Often we see the advertisement of a country grocer who says, "We pay the highest price for butter and eggs, and sell groceries the cheapest;" or, "We make the best goods;" or, "We lead the procession." I do not know but we shall have to confess that we have been just a *little* guilty of what I am now condemning. If the Lord will forgive us we will never do so again.

Suppose, for instance, I had said, "GLEANINGS is the best bee-journal, and always leads in the procession." Could Bros. Hutchinson and York have indorsed that without making a wry face? Well, I think not, very much. They might have made the corners of my mouth drop down a notch or two.

I suppose it is not stretching the truth very much to state that each bee-journal has a field of its own—a mission of its own—and each excels in its own particular line.

#### THE LANGSTROTH-MONUMENT FUND.

SUBSCRIPTIONS for the Langstroth monument are coming in very slowly indeed, and in amounts very small. An eminent bee-keeper from a foreign land, who had already sent us a generous contribution, and who now sends \$10 in addition, says: "I think it a blot on bee-keepers, not coming forward more liberally. . . . Are the bee-keepers of America really so poor that they are not able to raise a monument to Langstroth?" I do not believe it is because they are poor so much as it is because they are careless—that is, they *intend* to do something, but put it off till some other time, and that "some other time" never comes. If the *American Bee Journal*, the *Review*, and GLEANINGS keep on hammering, we may in time be able to raise funds to put up a suitable monument. If hammering will bring the money, GLEANINGS will keep on pounding, but for goodness' sake, let us not be a reproach to bee-men across the water. In the mean time, do not put it off, but send in the nickels, the dimes the quarters, and

the dollars. Langstroth was a real benefactor. He is not only revered by the bee-keepers of the United States, but by all Europe as well. Let us pay him this our last tribute. If the money comes in, and a suitable monument is erected, we will show a half-tone picture of it.

#### MY TRIP EASTWARD.

As our readers are aware, I have been planning a tour among the bee-keepers of the East this summer. I leave here for the Buffalo convention, and will go on from that point, after the convention, to Syracuse, where is located one of our branch offices. I shall make a circle among the bee-keepers of that vicinity, taking in Doolittle, Salisburys, and others; then on through Herkimer, Otsego, and Tompkins Counties; thence on to Providence, R. I., where I am to act as judge of the honey exhibit at the State Fair, which lasts from the 6th to the 10th of September. But I shall be at the exhibit, probably, only the 7th. I shall make a flying trip, going by rail for long distances, to save time, and using my bicycle to strike intermediate points and places not directly on the line of the railroad. But I am afraid I shall have to skip by a good many of our good friends, as my time and strength will be limited.

#### COMMISSION SWINDLERS.

ON page 500 of this journal for last year we published the name of Martin Brockman, a commission man in Cincinnati, who had obtained from Mr. Byron Walker some \$70 worth of honey, and who either would not or could not make any returns. At all events Mr. Walker was satisfied that Mr. Brockman tried to swindle him. He now sends me information, coming from the Postoffice Department, to the effect that this same Brockman, together with George R. Dixon, A. Hess, and Chas. Cook, made up a gang whose headquarters were in Cincinnati, and who had been conducting a fraudulent business through the medium of the United States mails. Report goes on to show that they were convicted in the United States Court, sentenced, and are now serving time as follows: Brockman and Dixon, four years each, and Hess five years and four months, in the Ohio penitentiary; Cook gets thirteen months in the Cincinnati workhouse. Such news is refreshing. It is a pity that Uncle Sam could not get after the glucose-mixers in the same way. If he could, I imagine that the business of the \$12,000,000 glucose trust, recently formed, would languish for want of respectable patronage.

#### THE NEW TARIFF RATES, AND THEIR RELATION TO APICULTURE.

ELSEWHERE I have referred to the tariff on glucose. In looking over a copy of the Dingley tariff bill, recently enacted, I find that the tariff on honey is 20 cents a gallon, and bees-wax goes free as before. White-pine lumber, of which hives are made, is subject to a duty of \$2.00 per 1000; basswood, \$1.00. The tariff on honey is, I think, unchanged. Its effect has

been, I believe, to keep out of our markets cheap honey from Cuba and Mexico. At first sight it might appear that the tariff on lumber would have a tendency to raise the price of hives; but, fortunately, there is a very large lot of lumber of good grade on the market, suitable for making hives, and this lumber is begging for a customer. It is what is usually denominated "shorts"—that is, it is lumber that is otherwise suitable for purposes of building, but too short to work to advantage on a house or barn. The very fact that the lumber-dealers are competing with each other to get rid of these "shorts" will prevent the tariff or any thing else from raising or lowering the price of hive lumber just at present.

Now, I hope that what I have said on the subject of the tariff will not be construed as having a partisan flavor. We have no room for any discussion of the tariff or free trade in our columns; and any article of that nature sent in for publication will be returned by the first mail. What is said above is neither for nor against the tariff—or, at least, it is not so intended.

#### DRONE-TRAPS VS. CLIPPING QUEENS' WINGS TO CONTROL SWARMING.

THE editor of the *Review*, in referring to what I said about chasing after swarms with unclipped queens, and that it was my determination hereafter to have all queens' wings clipped, whether our customers liked it or not, suggests that queen-traps will enable one to control a swarm without clipping. That is true. At our out-yard we used traps on all colonies having unclipped queens. But the perforated zinc somehow seemed to disconcert the workers, and then toward evening the bees of such colonies showed a tendency to cluster out more than on those hives having colonies of equal strength where the entrances were left unobstructed. But queen-traps are handy, "allice same." There were two colonies at the out-yard that were so very populous, and being a little on the hybrid order, it was not practicable to take time to hunt their queens, so I just clapped on entrance-guards and let them go.

It should be said, however, in connection with the entrance-guards, that they will prevent virgins as well as laying queens from going off with the swarms. It sometimes happens, unbeknown to the apiarist, that the laying queen is superseded, and a virgin or young laying queen takes her place. In such a case, if the old queen were clipped the bees could swarm and "light out" for parts unknown; but perforated zinc would hold them—or at least there would be very few virgin queens that would get through it, and in general practice there are none at all.

#### R. B. LEAHY'S VISIT TO MEDINA.

R. B. LEAHY, the supply-man of Higginville, Mo., and editor of the *Progressive Bee-keeper*, on his tour among the manufacturers and bee-keepers made us a brief call here at Medina.

The Leahy Manufacturing Co., like every other manufacturer of bee-keepers' supplies,

has had this year a heavy run of business; and Mr. Leahy himself, having worked many a night up to 12 o'clock, to keep up with his correspondence, found himself needing rest and a change. He accordingly sought the scenes of his old home by the seaside. After a good rest he started on his way westward, visiting Doolittle, the W. T. Falconer Mfg. Co., and finally stopping off at the Home of the Honey-bees. From here he expected to go to Mr. Hutchinson's; from there on to Chicago to call on Mr. York, and thence run on to the G. B. Lewis Co., the Page & Lyon Mfg. Co., and other supply-dealers. Mr. Leahy will, after his whirl over the country, get a pretty good idea of the bee-supply business.

He started, not many years ago, with hardly 25 cents to his name, and is now treasurer and general manager of the Leahy Mfg. Co., capitalized at \$24,000. When Mr. Leahy started in, there were scores of other small manufacturers, nearly all of whom have since given up the business. By energy and perseverance he has more than held his own, and has built up a business of no small proportions.

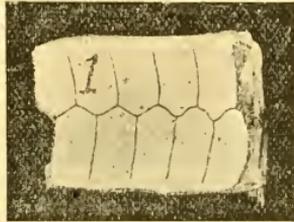

#### HOW BEES BUILD COMB, AGAIN; CONDITIONS UNDER WHICH THEY WILL MAKE MORE MIDRIB IN COMB HONEY THAN OTHERS.

SINCE our last issue, but before it reached Mr. Doolittle, we have received a letter from our Borodino correspondent, sending in his report of the new drawn foundation. He finds it no more quickly accepted by the bees than foundation, nor finished any sooner, and that, after being completed, it has a "resistance in cutting far greater than that built on common foundation." He winds up, "I had hoped it would be a boon to bee-keepers." It will be remembered that Mr. Doolittle was very favorably disposed toward the new article when it was first introduced; and, so far from believing it would work disaster to the industry, he expressed himself as believing it would be a great stride forward.

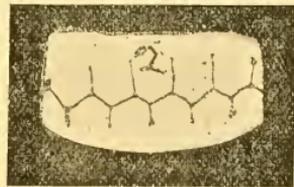

As the results secured by Mr. Doolittle were so different from those obtained by us, Dr. Mason, Burt, Iper, and others,\* we began a careful and more thorough investigation. Mr. Weed and I overhauled our sections containing comb honey that the bees had made off from the new foundation; for it will be remembered that, in our eating-tests on the two different lots (see page 529), no one of our Medina folks could tell the difference between combs of honey built from drawn foundation and that from the ordinary product. We knew Mr. Doolittle to be a very careful and conscientious observer, and set about to discover *why* he should have such a different result. The drawn foundation we sent to him arrived near the close of his season; or, at least, Mr. Salisbury, living within thirty miles of him, and to whom we sent a similar lot on

the same day, reported that the season was fast waning.

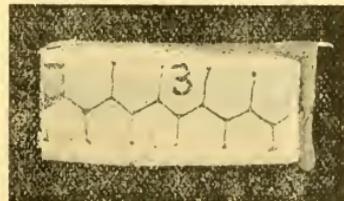

Well, in going over our sections of comb honey from drawn foundation we finally found some specimens that had heavier bases or midribs than some other lots that we had been testing, and which seemed to be all right. In order to get a better cross-sectional view of them they were placed in plaster casts, as were also pieces of worker comb built wholly by the bees, natural-built drone comb, drawn foundation *before* it had been in the hive, and another specimen after the bees had worked it out. Cross-sections were taken of each, and the results reproduced in half-tone. No. 1 shows natural worker comb without founda-

tion of any sort; but it was when the honey-flow was good. No. 2 is also a sample of worker comb built wholly by the bees. But you will observe that its walls, and especially

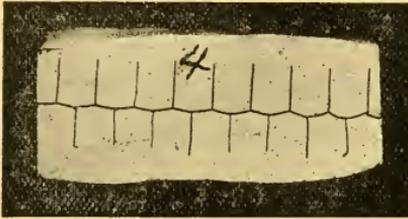

its bases, are very much heavier than those of No. 1. But No. 2 was built *after* the honey-flow, and at a time when the bees had plenty of leisure to put in a surplus of wax. No. 3 is an ordinary specimen of drone comb built

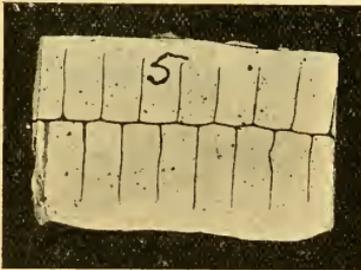

during the flow of honey, and, as we have before shown, the base and walls are considerably heavier than in the case of No. 1. No. 4 is a sample of deep-cell (or drawn) foundation from the latest dies, before the bees had done any work on it. No. 5 is the same foundation drawn out during the honey-flow. But

\* Since writing this we have heard from B. F. Onderdonk, Mountain View, N. J., who says: "Have tried a section of the 1/4-inch drawn foundation, and find it perfection to the palate, and no gob."

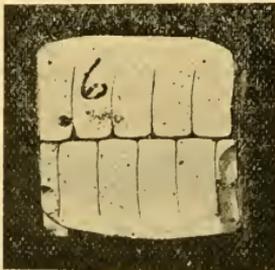

you will notice, somewhat at variance to our experience previously reported, the bees thickened the bases a trifle, and also thinned the walls near the top edges. No. 6 is comb built

from drawn foundation, as shown at 4, but it was drawn out when the honey-flow was waning, and the bees had more time to chink in a surplus of wax, just as they do in case of their own natural product, as shown in No. 2.

It will be noticed in this connection that there are times when bees make much heavier walls and bases in their comb-building than at others, and that those times vary according to the strength of the honey-flow; whether it is

on in full blast, is waning, or has stopped altogether. Bearing in mind these facts, it is easy to reconcile why Mr. Doolittle should have secured different results from those obtained by us. When we placed our deep-cell foundation on the hive, it was during a time when honey was coming in well; and it would seem, therefore, the bees used, with slight modification, any thing and every thing that had cells into which they could pile their honey, as they had not time to draw out the

ordinary foundation. In the case of Mr. Doolittle, the honey-flow was waning, and, as drawn foundation has flat bases, the bees were probably halting between two opinions—on the one side, whether they should utilize cells already drawn out, but which had flat bases that they didn't like, or should stop to draw out the foundation that had natural bases. As they were not able to give them an hexagonal form they did the next best thing, and filled up the corners with wax, as will be seen at 6, and to a less extent in 5.

The result of all of this goes to show that we were honest in reporting what we saw, and Mr. Doolittle was equally honest in reporting exactly what he observed. It is evident, then, that, even in deep-cell (or drawn) foundation, flat bases do not always suit the bees, and that there are times when they will try to remodel those bases by sticking in more wax, and thus making a more perceptible midrib.

Mr. Weed, who has made all of these plaster casts, and has given me all of my pointers, assures us that he can make drawn (or deep-cell) foundation, if you please, with natural bases. His first idea was, in fact, to make such bases; but his experiments last summer led him to believe that flat bases, when deep walls were used, were just as good as natural. But Mr. Doolittle's letter caused us to stop and scratch our heads, and go all over our experiments again more carefully; and the result is that Mr. Weed has about come to the conclusion that natural bases are better, even in the case of deep-cell foundation, and he now proposes to remodel his bases; and this, I have no doubt, he will do successfully.

I am willing to acknowledge that, in one respect at least, drawn foundation is not what we at first hoped it would be, but in only one respect, and this in relation to the matter of the bases; but if that is the only trouble we can easily remedy it.

But there is one thing we can not do, and that is to prevent the bees from building their all-worker combs heavier at some seasons of the year than at others. A few weeks from now we hope to show you samples of drawn foundation having natural bases instead of flat, said bases being just as thin as the bees make them. Probably the walls will be a little thicker near the bottom of the cells than at the top. But that makes no difference, because the bees like the job, seemingly, of thinning down the walls, for we know they almost invariably do so.

#### THE CONVENTION AT BUFFALO.

By using my wheel I have managed to get home just before the last form goes to press, and find I have but little space left to tell a long story. I can only say here that this session has been, if not the best, one of the best ever held by American bee-keepers. How could it have been otherwise? We had all the great lights, besides some who have never been with us before, or not for many years. J. F. McIntyre came all the way from California, as did Mr. B. S. K. Bennett, editor of the *Pacific Bee-keeper*. Capt. Hetherington was present with two of his brothers. Poppleton, of Florida, was on hand, and others.—A. I. R.

THE GREAT SEEDSMEN OF PHILADELPHIA  
AND VICINITY.

I was greatly pleased to discover the pleasant relations that exist between all of the Philadelphia seedsmen. Burpee, Landreth, Johnson & Stokes, Maule, and Dreer were all visited; and instead of clashing or conflicting, each seems to occupy more or less a field all his own. For instance, Landreth grows seeds on his great farm, perhaps more than any other institution of the kind in the world. Greer has the most extensive and up-to-date greenhouses, filled with tropical plants. Burpee is the great originator or introducer of new and improved vegetables, although all of them grow more or less in this line of work, and so on through the list.

My first visit was at Burpee's. Their large building with its many offices was, as a natural consequence, quiet and still for the most part, at this season of the year; but I could not help admiring their arrangements and appointments for doing a large business with speed and dispatch. Mr. Burpee himself was absent in Europe at the time of my visit; but I was very kindly given most complete directions for reaching Fordhook; and while I was waiting for a train at that beautiful depot, Spring Garden, I greatly enjoyed looking about me. This depot is on an elevated platform above the streets. In fact, it is almost an elevated community; and trains are coming in and going out so constantly that one wonders what it can all be for. The appointments and arrangements to prevent mistakes and accidents are most wonderful. While I was viewing these things a fine-looking young man came up, evidently in some haste, and, touching his hat, said:

"Is it my pleasure to be addressing Mr. A. I. Root?"

I smiled while I assented, and then asked him what he knew of A. I. Root, anyhow, for I considered myself an entire stranger in a strange land. He said he had just learned that I was in the city, and that I had started out to Fordhook Farm; and although he had just come from there he said it would afford him great pleasure to go right back and show me around. I remonstrated a little about making so much trouble; but he would have his own way.

All along our route I was again impressed with the beautiful surroundings in the way of homes and homelike decorations. At Landsdale, where we changed cars, on a little bit of green lawn belonging to the depot building I saw the finest piece of bedding, with ornamental foliage-plants, that it has ever been my fortune to find anywhere. It was morning, and the dew was not yet off the plants; and when my eye caught it I made a start of surprise. The center-piece was a round bed perhaps ten

feet across; then radiating from this center were ten oblong beds about the shape of a cucumber seed. They radiated from the center-piece like the petals of a flower. These beds were, may be, twenty or twenty-five feet long. The outside, next the grass, was, if I remember, a line of what I should call "dusty miller." Then came another line of dark-purple colei, and inside of this was a center of golden bedder; and the golden hue was so bright and vivid that it almost made one think of a flame of fire or a most brilliant patch of sunlight. Now, this alone would have been to me fascinating; but, sprinkled all along the dividing lines between the golden and purple colei, were geraniums, in two colors, in bloom, the deep dark red contrasting strongly with the lighter pink. The whole thing burst upon me exactly like strains of music. Why, I do not think it is too extravagant to say that, for the time being, I was almost entranced.

I wonder if there are other people like myself. I have attended great concerts, and listened to classical music from some of the great scholars, without feeling very enthusiastic; but when I was in Atlantic City waiting for dinner, after my bath in the salt water, I was startled by strains of music of wonderful pathos. I discovered that it came from a little Italian girl who was playing on some sort of accordion. She was grotesquely dressed with a quaint sort of cap or covering for her head. This covering was made of different-colored soft fabrics; and the head-dress, with the dark complexion and eyes underneath, gave me a thrill. Why, it seemed as if I never listened to strains of music more beautiful. Then when a childish voice broke in a little later, I stood drinking in the great flood of joy that filled my soul, wondering how it came that God saw fit to send these thrills to me so unexpectedly. Well, it was just the same way with that beautiful bed of bright colors, with its vivid entrancing background of green. I purposely turned away several times to see if, when I looked back again on the beautiful scene, it would give me such a thrill.

In talking with Mr. Dreer afterward about his great greenhouses he said he thought the railroad companies were doing a grand thing in the way of educating the world in general, by these beautiful "object-lessons." He said many a farmer, while traveling, had, to his knowledge, made resolves that he too, when he got home, would have a little bit of lawn and some of those handsome plants.

Now, before I take you to Fordhook Farm let me remind you that we are indebted to W. Atlee Burpee for some of the most popular and valuable vegetables now known to the world. First, and perhaps best, Burpee's bush lima bean. Why, we hardly sell pole limas now at all since this has become to be well known. Burpee's Sure-head cabbage has become a household name, almost; and the self-blanching celery, introduced in 1884 — why, what would the world do without it at the present time? We might say almost the same thing of the Emerald Gem melon. The white Victoria onion has been one of our favorites ten

bunching, for many years. Burpee's Extra-early potato is almost a standard in many localities; and the Matchless and Fordhook Early tomato and Breadstone turnip are things that seem to have come to stay.

On the way to the farm I told Mr. Earl, my companion, how long I could stay in Philadelphia, and the places I wanted to visit. He said, as did friend Selser, that my stay was altogether too short; but that, if I insisted on carrying out my program, I had better leave my wheel at the station, and he would get a rig and give me at least a glimpse of what they had to show, in the shortest time possible. I do not know but I did express my surprise that Mr. Burpee should leave his entire plant in charge of a man so young as my companion—a boy, almost. In fact, he told me he was only 27 years old. I soon concluded, however, that Burpee's head was level in selecting a general manager. By the way, in our own work at home, a great many times old and trusty men have felt deeply grieved because some younger one was promoted and put over them. Dear friends, we who manage business often think of this. But God has seen fit to give some people special talents; and, even though it hurts to bow our head in submission, it is the right and proper thing to do.

I was first taken into the office and shown the books of record. Those who have undertaken to test and compare new fruits and vegetables know something of what a task it is. Different foremen on Burpee's farm make it their business to plant the seeds, watch and care for the plant, study its habits and peculiarities, and note it down in an appropriate book. This is not done for only one season but a series of seasons. Nothing is put into the catalog until it has stood the test, and found to be beyond question superior to the old sorts. You may inquire why it is that we have fifty or sixty varieties of peas, and other things accordingly. Well, it is a hard thing to drop an old variety. In cutting down our catalog I have several times decided to drop such and such things; but I have learned that there is sure to come a wave of disapproval when I decide to rule out almost any thing that has been previously cataloged. If it is not somebody in Florida who has found that very thing just suited to his locality, it is somebody out west or down east or up north.

Of course, the flower business, which is the great specialty at Fordhook Farm, was rather out of my line, although I did greatly enjoy looking at the beds of the new Sunset large-leaved colens. At Fordhook Farm, things are arranged mostly for testing varieties or for growing seed; therefore I did not find much that stirred me as did that ornamental bed by the railway station. A field of mixed verbenas, just in full bloom, was a most pleasing sight. Just imagine a buckwheat-field, one of the whitest you ever saw, with the flowers of all colors of the rainbow, and you would get the effect. Of course, sweet peas were a grand sight, for Mr. Burpee is one of the greatest, if not at the head of the sweet-pea growers of the world. I greatly enjoyed looking over a field of tomatoes grown expressly for seed and

nothing else. Some of them were just beginning to color at the time of my visit. I saw a spring, or little run, where they wash the seeds from the pulp, in getting the seed ready for market; and I smiled as I asked my friend if that was where the ducks formed habits of intemperance.

"Yes, Mr. Root, that is where the ducks got drunk; and we were sorely puzzled for a good while to know what ailed them, and what made them die, until somebody suggested that the pulp the ducks were feeding on had fermented until it was intoxicating."

Yes, it was indeed true. The ducks not only learned to get drunk, but, instead of profiting by experience, as soon as they recovered enough to get back to the stuff that was killing them they got drunk again and again until they actually died. Finally their owner was absolutely obliged to fence them off and permit them to have access only to the fresh tomatoes from which the seed had just been taken. We may pardon the ducks, because they are only dumb brutes anyway; but what shall we say of human beings, made in God's own image, who follow their example? Burpee keeps abreast of the times by offering for sale every thing worthy of being cataloged, and I believe he sometimes offers for sale some things that are not worthy of being cataloged, were it not that they have already been widely boomed. For instance, in his catalog for 1897 he says of scalline, "It is comparatively worthless as a forage-plant in America." However, he offers it to any who want it, for 10 cts. a package. After describing *Lathyrus sylvestris*, or flat pea, he says: "As a forage crop it can not compare with Indian corn, cow peas, etc."

I was much pleased with another notice, to the effect that visitors were always welcome on any day *except Sunday*.

Burpee not only grows flowers, but he is an enthusiast on fine poultry; and his poultry-houses and yards are the most perfect in the way of cleanliness of any thing I have ever found. Why, you could sit down and read a book right where the fowls roost, and not notice any unpleasant smell. I presume this is managed by cleaning the houses every day, and by the proper use of dry dust as a deodorizer. His kennels for collie dogs are also models of cleanliness and good taste. It seemed really too bad, however, to keep the intelligent little fellows shut up when they begged so piteously to get out. When I asked the price of some of the good-looking little puppies they said they were already sold at something like ten or twelve dollars apiece, and some of them are sold before they are born.

Although I did not have the pleasure of meeting Mr. Burpee himself, I was very agreeably entertained by Mr. B.'s bright and intelligent sister, the manager's wife, Mrs. Earl, and the little ones of their pretty home. And, by the way, right by this home, and, in fact, with its branches spreading clear away up above and over the roof, is one of the largest basswood-trees I ever saw in my life; but, strange to tell, they have never noticed any honey-bees around it when it has been in full bloom. I

wonder if there are no bee-keepers around Fordhook Farm.

## OUR NEIGHBORS.

And as ye would that men should do to you, do ye also to them likewise.—LUKE 6:31.

I told you of the many attractions constantly exhibited at that great bathing-place, Atlantic City. Prominent among them was the comparatively new vitascope, a most wonderful invention in optics. It really amounts to a photograph of living *moving* figures. Here were perhaps a dozen or more of these instruments, each one having different subjects. Friend Selser and I looked at a few of them; but several of the subjects that I knew by reputation, and some I had seen in different cities, I told him were, in my opinion, unfit for any one to look at. It gave me pain to notice these were the very ones most patronized. While we were standing near one of the places of exhibition, friend Selser met an acquaintance; and while they were talking I looked about me, and especially studied with deep attention the great throng of humanity then on every side, for it was toward the middle of the day. Right near me was one of the vitascopes, labeled "Working the Typewriter," or something similar. I had avoided it before, for I knew something of what it was; but this one, judging from its shopworn look, had been handled most of all; and while I was waiting I thought that perhaps it would be a good plan for me to investigate and see just *why* this one attracted more attention than the others. I dropped my nickel into the slot, and commenced to turn the crank slowly, according to directions. The scene was a business office — clerks hurrying here and there, typewriters flying rapidly, boss giving orders, etc. In the foreground was a very pretty girl hard at work with a typewriter. A good-looking man with gray hairs and gray whiskers sat near reading a letter. In the opening scene there were quite a number of clerks in the office, as I have told you; but one by one they seemed to take their departure. Perhaps it was toward the closing hours of business. Finally the pretty girl and the boss were alone. He hitched his chair a little nearer to his clerk. Pretty soon, looking about, evidently to see that the room was empty, he patted her on the cheek; and it was not long after that before they were exchanging kisses. At length she stopped her work and put her arms around his neck, he likewise clasping her as if he might have been her father, and she a girl of ten or twelve. Her looks, however, indicated her to be twice that age. Just about this crisis a middle-aged fine-looking woman was seen cautiously coming into the room with noiseless steps. She came unperceived until she stood over the guilty couple. The girl, in her fright, jumped up and retreated, while our friend with the gray hairs went down on his knees before his indignant wife, and in a most humiliating way begged to be forgiven, no doubt promising

that such a thing should "never happen again."

I presume some time and money were spent in getting up this little tableau or theatrical, or whatever you may want to call it. The look of righteous indignation which shone from the fine-looking woman's face seemed as if it could hardly have been put on. Then the shamefaced, cringing manner of the gray-haired sinner, and his more youthful companion, the typewriter girl, was *more* than reality. The woman listened to her husband's apologies and promises with some softening in her countenance, but she turned about and glared at the typewriter girl, shaking her fist at her meanwhile, and saying by her looks, plainer than any words could say it, "As for *you*, you good-for-nothing hussy, see that you never darken the doors of this office again;" and that was the finale. If you were to turn the crank any further you would commence over again with the office full of clerks, and every thing in proper decorum.

Now, you may wonder why I go over this. Perhaps almost everybody has seen it. They pay their nickels and have a big laugh, and tell their friends about it, and it is (or doubtless was) the funny thing of the season. Let me digress a little.

To fill out my program of visiting a number of seedsmen and their grounds at Philadelphia, friend Selser said we should have to do quite a little traveling. When we got on to the trolley-cars, to make any thing of a trip he got permission to put me in front beside the driver, and it was a rare treat indeed. I not only saw the wonderful sights of the great city as friend Selser pointed them out, but I received a great deal of information in regard to the rules and regulations for running electric cars. Almost constantly, especially during the busy part of the day, on Market and Chestnut Streets, the crowd would be so great that it seemed as if somebody would certainly be hurt; but I did not see an accident. At the crossing of the car-tracks the cars follow each other so closely that a novice like myself would think there *must be* a collision. At one time our car was going down quite an incline. At the bottom of this incline another car-line crossed ours at right angles, but there was scarcely any slacking up in order to pass. Our car went down the hill like a shot; and when within a very few feet of a car loaded with human beings it would slack up just enough to let said car whizz by. Sometimes it seemed a question as to which driver had the right of way; but I was told there were rules governing this thing, and that the drivers rarely or never made a mistake. Two cars would approach each other as if they were going to collide, with terrible consequences; but one would always slacken up just enough (and no more) to let the other glide out of the way.

Now, if you please, let us suppose that one of the drivers — the one going down hill, for instance — were a vicious man. Suppose he should run into a carload of passengers — possibly a family of little children. Suppose he were to smash the car into splinters, and throw

the maimed and dying to the right and left, crippled for life, and perhaps crippled and maimed himself. Now, suppose this man should say he did it for *fun*—for a joke—what would be thought of him? Why, I am afraid they would lynch him as they have been doing lately, in terribly extreme cases. If he were to try to get out by saying he had suddenly become crazy, I do not know but community would think *such* a crazy man should be put where such a craze would never get hold of him again. If anybody should laugh at the occurrence, pretending he thought it was *funny*, this fellow would be in danger also. If our laws are not always thoroughly enforced, the one who undertakes to trifle with human life in the way I have described will pretty soon find there are officers, and public opinion back of them. Let us now go back to that little scene, the vitascope.

This gray-haired man, a gentleman and a scholar, possibly the proprietor of the establishment, deliberately plans something *worse* than the crazy notorman of my imagination. He wrecks a home—yes, oftentimes makes a worse wreck than will result from broken limbs and mangled bodies. This good-looking young woman, so skillful with her typewriter, deliberately consents to be a party in making this wreck and ruin. I do not put so much blame on her, because I think the man (or the person who is *supposed* to be a man) is as a rule by far the guiltier one of the two. He coolly and deliberately breaks his marriage-vow. He knows the consequences; and, in fact, if any one should presume to trifle with his wife or daughter in the way he is doing, he would very likely consider himself excusable for taking the law into his own hands. If he used a revolver, our courts would almost call him excusable. Oh what inconsistency! what a terrible thing is sin or Satan when it or he enters the human heart! Do you say that I am moralizing on a play in a vitascope, and that no such thing ever happened? Dear me! just take up one of our dailies and read a single issue. Men, and women too, and men who are *not* crazy, deliberately crash into and break up a family, estrange husband and wife, send the children out homeless and friendless, to care for themselves as best they can, or let the poor mother drag along and support them alone. If we were not as a people losing proper respect and reverence for the sacred institution of marriage, divorces would not be coming as thick and fast as they are nowadays.

Let us now go back to the bathing-ground, with its hundreds and thousands in their costume that has been so much condemned. It may be a dangerous place for both sexes; but, in my humble opinion, it is not a tenth part as dangerous or as bad as a business office where a man (no matter what he professes) spends many hours alone with no companion but a pretty young woman to manipulate his typewriter. I believe that men and women should work together, but not two solitary persons of opposite sex and not related. I do not believe very much in private offices. Let your business affairs and all your communication with your fellow-men be of such a character that

you have nothing to conceal from the eye of God or from the eye of man. The bathing-resorts are comparatively safe—at least what I have seen of them, because there are such crowds all around us. I accidentally found out that policemen are stationed at every hand; and any indecorum, even if it be accidental, is promptly looked after, and the offender taught a lesson. I have often thought of paraphrasing this beautiful golden rule that I have chosen as my text. In fact, some of the experiences I have passed through in this life that God has graciously seen fit to give me to live have made me meditate often on this paraphrase, and I think I will put it something like this: As ye would that men should deport themselves toward your daughter, sister, or wife, both in act, word, and in thought, do ye also likewise to every other man's daughter, sister, or wife, in act, word, and thought.

The great wide world seems to think that lapses from virtue in the direction I have indicated are only a thing to laugh at; but, may God be praised, of recent date once in a while things of this kind are beginning to be recognized in their true light. Parnell, with all his scholarly attainments, wealth, and position, did not succeed in getting mankind (and especially *womankind*) to look at his sin and crime as a joke; and I for one protest against the custom of laughing and making merry over things of this kind, or in passing them off as a joke, or even as a funny thing in any sense of the word. It makes me sad to think so many people will look at this particular vitascope picture, and advise others to look at it and laugh. Let us remember the old-time fable of the boys pelting the frogs—"It may be fun for you, but it is death for us."

#### HIGH-PRESSURE STRAWBERRY-GROWING AND SUB-IRRIGATION.

Under this head I expect to tell how everybody can raise strawberries. If you live on a farm, of course you have ample facilities for growing them by the acre. But an acre is almost too great an area to be employed in *high-pressure* strawberry culture, unless, indeed, you expect to hire help. What I have in mind more particularly just now is for people who have just a garden—say a small garden. But if you haven't ground enough for a garden, and have only a few rods where you can get sunshine, you can grow wonderful strawberries even there; and if there be such who read GLEANINGS, who have not even a few rods, if they have even a few *yards* of ground where the sun may shine a part of the day, and where the plants may get the benefit of the summer showers, they may have much enjoyment and much delicious fruit, even with

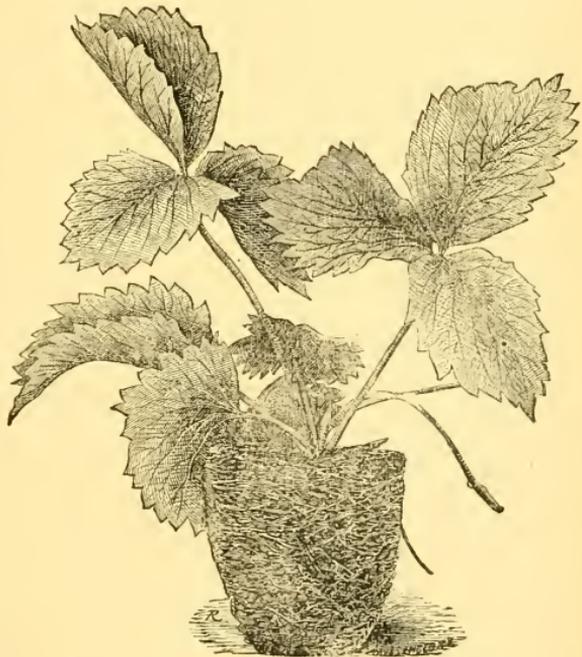

a few yards. Almost the only condition is plenty of daylight. During mid-summer, very fine strawberries may be grown entirely in the shade; but during the rest of the year it is much better to have the sunlight.

Few people are aware of what wonderful things can be done with strawberries where they are provided unstedily with water and plenty of fertility. You need not urge that it will not pay; for if you get interested in the matter, I think the *enjoyment* will almost pay you, to say nothing of the luscious fruit; and then the pleasure of being able to astonish your friends by showing them strawberries as large as small-sized hen's-eggs, and almost as perfect in shape, which you may do with some of our finest new varieties!

To commence with, we must have sub-irrigation; and when you succeed in managing sub-irrigation for strawberry-plants you have the matter fully in hand so you are ready to apply it to almost any other crop. You may commence on a very small scale at first — in fact, I rather prefer you should do so. When you make a success of this small scale you can easily enlarge it as much as you choose. Perhaps the present month of September is as good a time to start as any, for we can now lay the foundation for great bushy plants to furnish us quantities of immense berries next spring. For sub-irrigation you must have some sort of bed or box that will hold water; and you can start the business very well with a large-sized common wash-tub, if you do not like to go to the expense of making a water-tight box. A tub would be rather deeper than is necessary, but it will illustrate the plan. Provide some good finely sifted garden soil — enough to fill the tub a third full. Then get some old well-rotted manure, old enough so you can work it through a coarse sieve. Such a one as is used for screening coal ashes will answer very well. Have equal parts of garden soil and sifted manure. A little clean sand and some swamp muck will help make a nice compost if you have materials handy. Set a common drain-tile on end at one side of the tub, and fill in with the compost. Now you want a strawberry-plant. The plant should be a young one; but if you can not find a young one, almost any strawberry-plant will do. But I would start with a *potted plant* (see cut) of one of the very best of the new varieties, because it is just as easy to propagate high-priced plants as low-priced ones. Set the plant in the middle of the tub. Let your tub stand where it can get both rain and sun; but should there be a *very* heavy rain so as to endanger filling the tub with water so it rises above the soil, the tub must be covered — that is, when the soil is wet

enough. If it does not rain, pour water into the tile until it rises and stands say two or three inches below the surface of the soil. This water underneath will always keep your soil damp enough. But do not water your bed *every* day. Air through the soil at intervals is as important as water at intervals.

If the weather should happen to be dry and warm, evaporation will take away the water until it sinks in the tile almost to the bottom of the tub. When it gets down say within an inch of the bottom, then fill it up to within an inch or two of the top; then let it gradually sink down again. If you have rain every two or three days you will not need to water your little bed at all. But keep watch of it, and do not let the plants get drowned by *too much* water, nor dried out by lack of water. When the plant gets to growing vigorously it will put out runners. Spread these out like the

A POTTED STRAWBERRY-PLANT JUST BEFORE IT BECOMES POT-BOUND.

spokes of a wheel, and let them take root. But a better way is to plunge a little pot, say two inches in diameter, down to the surface of the soil, and make the plant take root in the center of the pot. This enables you to move your young plants without having them stop growing. Above is a cut of a potted plant when the roots have filled the pot so that it needs to be taken out and given more room.

What is meant by "pot-bound" is letting the plant remain until the roots have so filled the pot that they become cramped and stunted. If you start plants in pots you must be sure to take them out before they become pot-

bound. The plant, with all the soil adhering to the roots, is easily removed from the pot by turning it over and striking the edge of the pot a smart blow on some solid body — the edge of the tub, for instance. When your plants are ready to come out they should be put out in a similar tub, and placed at least three or four inches apart. If you want them to bear fruit they should not stand nearer than six inches. If you are going to keep the runners cut off, and grow them in hills, they ought to be planted as much as two feet apart. The largest and finest berries are grown by the hills system. This has been fully described in our strawberry-book.

Now, in the above you have the whole thing in a nut-shell. Sub-irrigation is certainly the way to grow strawberries. The objection to it is the expense of having water-tight beds. You can probably make a wooden box much cheaper than a tub; and if you are going to make a box it ought to be large enough to take for a cover a common-sized hot-bed sash, the regular run of these being 6 feet long by  $3\frac{1}{2}$  feet wide. This box can easily be made sufficiently water-tight of lumber well nailed together; but it is generally considered cheaper to take less pains with the lumber and the carpenter work, and make the joints tight with water-lime cement.

There are many opinions in regard to the depth of soil needed to grow plants; but I believe four or five inches is deep enough. Perhaps you had better have six inches of soil and manure. With the glass sashes I have spoken of you can protect the plants from frost, and have strawberries one or two months earlier than you can get them in the open air. The sash can also be used to keep off surplus rain when observation shows you there is enough in the bed. For a bed 3 by 6 feet you will want at least two tiles—one in opposite corners; and if you expect to neglect your bed, and let it get full of water during some heavy rain, you will need a hole bored down close to the bottom, with a cork to stop it up. But I do not like this arrangement. Whenever you let water off because you have so much as to drown the plants, you are leaching away the fertility of your soil. That is the way we do in all outdoor farming and gardening, but it is a bad way nevertheless. A small quantity of manure will do a tremendous lot of fertilizing in growing plants if we never permit the fertility to be leached away and washed away by excessive rains.

Well, after you get your sub-irrigating strawberry-bed, 3 by 6 feet, to working nicely, you are ready to try a larger one. Your bed may be 6 by 6 feet, so as to take 2 sashes, or it may be 6 by 12 so as to take 4 sashes; or you may have it 6 by 50 feet so as to take 14 sashes. That is the size of bed we use in our high-pressure gardening. I would not have it more than 50 feet long, because you have to carry the sash so far when you pile them up at each end of the bed. You will find cuts of these beds in our tomato-book.

"But can we not," somebody is always inquiring, "practice sub-irrigation outdoors?" We can; but a heavy rain is sure to fill up our

beds and necessitate drawing off the water. It works all right in a greenhouse where you have control of the water supply; but I do not know how sub-irrigation can be made a success in the open air unless you arrange valves to be opened to let the water off when there is too much of it; and the water that comes out of these valves will show by its color that it is carrying away the fertility of your manure. And is not this an objection to *all* kinds of underdraining? Yes, my friend, it *is* an objection; but it is much better than to have the plants drowned by a surplus of moisture. These water-tight beds are expensive, I know; but for high-pressure gardenwork they are almost a necessity. When you have them nicely arranged you can push strawberry-growing or any thing else right through the most severe drouth; and with the sashes put over your plants, you have nothing to fear in the way of frosts. I suppose, however, such arrangements will be particularly used for supplying yourself with extra-strong vigorous plants to put in the field, say during August and September; and if the plants are of some new variety that commands a high price, you can push your propagation without regard to what the weather may be.

These plant-beds should stand exactly level. If they do not, the water you introduce through the tiles will settle to the lowest point, and you want it disseminated equally all through the bed. With beds say 50 feet long or less, two lines of tiles should run the whole length of the bed. These are laid in cement, and the joints closed half way up the diameter of the tile. With this arrangement the water may be introduced, say, at each end; and you will in time moisten the soil equally the whole length of the bed. Now, while the bottom of the bed is on a dead level to facilitate even watering, the sashes should have an incline when placed on top of the bed, so as to carry off the rain water; therefore the north side of the bed should be an inch or two higher than the south side.

---

#### OXYDONOR, ELECTROPOISE, AND OTHER LIKE HUMBUGS.

One of our readers asks us if the New York and London Electric Association, with its electro-magnetic hair-brush and comb, and other things, is after the same stripe as the Oxydonor. We sent for one of their circulars. Just half a dozen lines of their claims tell very plainly where they belong. And let me say in general, when you get hold of any circular containing such unmeaning harangues, set the party down at once as a fraud, without reading any further. One of their traps they claim will cure cold feet, and they start out with the following: "We will answer the question in simple language. In the first place, the human body is an electric battery, the upper half being positive and the lower limbs negative." Exceedingly "*simple*," is it not? Electricity is getting to be a matter of every-day fact to too great an extent for anybody of intelligence, or even good average

sense, to be humbugged by such statements. In regard to their electric hair-brush, which cures "nervous or bilious headaches and neuralgia, prevents baldness, and falling-out of the hair, cures and prevents dandruff and all diseases of the scalp," they make the following statement: "The brush is permanently charged with electro-magnetism in manufacture." I do not exactly understand why these charlatans, the whole tribe of them, have the same lot of meaningless set phrases and absurd statements that they keep harping on over and over again.

#### LARGE ORDER FOR FOUNDATION-MILLS.

During the past month we received from Russia the largest order ever booked for comb-foundation machines. It calls for six 14-inch, twelve 12-inch, and twenty-four 10-inch mills, besides a lot of other goods.

#### TUPELO HONEY FROM FLORIDA.

We have about 1000 lbs. of very fine tupelo honey from Florida, in three barrels, which we offer at 6 cts. per lb. for the lot. We shall be pleased to mail a sample free to intending purchasers; to others for 5 cents. The honey is light amber in color, and has the same peculiarity as California sage honey in that it remains liquid in cold weather. This makes it desirable to those who put up honey in glass to retail.

#### HONEY MARKET.

We are having a fair demand for honey, both comb and extracted. We hear frequently from bee-keepers who are developing their home market, and who have sold all their honey and need more. We are very glad to be of service as a medium of exchange between those who have a surplus and those who have not enough to supply their home demand. So far we have sold honey, especially comb, as fast as we have secured it. We have several places in view where we can use more to good advantage. If those not too far distant, having honey to sell, will write us, telling how many cases of each grade as graded on page 506 of current volume of GLEANINGS, the size of the cases, whether our make or no-drip, and the price at which you hold it, we may be able to help you dispose of it quickly to good advantage. In the case of extracted honey, send a sample bottle by mail, and tell what kind of package it is in, the number of packages, and the price you expect.

We offer water-white California honey, in 60-lb. cans, two in a case, at 6½ cts. per lb.; light amber at 6 cts. Large lots quoted on application. Samples free by mail to prospective customers. To those who would like to see a sample and compare it with their honey we will mail samples for 5 cts. each, the cost of the package.

Fancy comb honey, in 100-lb. lots and upward, 13 cts. per lb.; No. 1 at 12 cts.; less than 100 lbs., 1 ct. per lb. more. Large lots quoted on application. Correspondence solicited from those interested.

#### HONEY-LEAFLETS.

Perhaps no offer which we have made recently has been more popular than our offer to furnish honey-leaflets to our readers and customers up to 50,000 at simply the cost of mailing them. An edition of 25,000 was gone in five days; the next edition of 14,000 was hardly dry before it was all gone. The third lot, of 31,000, was used up in three or four days. By the time this issue is mailed we shall have sent out over 100,000 of these leaflets. We are glad of the privilege of contributing so much to bee-keepers to develop a larger use for honey. If all these leaflets are judiciously distributed it is impossible to estimate the amount of influence they will have in increasing the demand for honey. We are preparing the leaflet in a more convenient form. It will be a folder, the right size to slip into an

envelope without folding. It will also be provided with space on the front and back pages for printing the address or advertising card of the one who distributes them. We have had a call for them in this way. We will book orders for this style of leaflet at \$1.00 per 1000; 5000 for \$4.00; 10,000, \$7.50; \$1.00 extra for your address and business card on one page; \$2.00 extra for both first and last pages printed special. We shall not have these ready for two or three weeks; and if there are any recipes, tried and found good, which are not in the present leaflet, we should be pleased to have you send us such at once. Here is one which has been tried and found excellent:

#### HONEY-DROP CAKES.

1 cup honey; ½ cup sugar; ½ cup butter or lard; ½ cup sour milk; 1 egg; ½ teaspoonful soda; 4 cups sifted flour.

Our offer to give away leaflets was only for the month of August. We shall be pleased to sell them to those not already supplied, or who may need more, at the regular prices, which barely cover cost: 100, 20c; 250, 40c; 500, 75c, postpaid; 75c per 1000, sent at your expense with other goods.

#### GLEANINGS AT REDUCED RATES.

New subscribers sending us \$1.00, or subscribers who have paid up all arrearages, and send us \$1.00 before their subscription expires, will receive a copy of the A B C of Carp Culture, 70 pages, price 40 cts., postpaid, the pages the size of these; or we will send, in place of the carp-book, one copy of Winter Care of Horses and Cattle, by T. B. Terry, a book of the same size as the carp-book, 41 p.; price 40 cts., postpaid; or in place of either one of the two we will send Maple Sugar and the Sugar-bush, a book of the same size, costing also 40 cts., postpaid. Remember, in order to get one of these valuable books all you have to do is to send \$1.00 for GLEANINGS, and 5 cts. postage, and we will give you one of them free. An old subscriber, to be entitled to this offer, must pay up all back subscription, if any, and send in \$1.00 for a year in advance, with 5 cts. postage.

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

#### GARDENING FOR SEPTEMBER.

Now is the time to put in American Pearl onion-sets. We have a nice stock; also Prizetaker sets and White Victoria. The two latter have succeeded nicely when put out at the same time as the American Pearl. The ordinary white and yellow sets, however, do not seem to stand the winter as well. Prices of any of the onion-sets mentioned above, quart, 20 cts.; peck, \$1.00; bushel, \$3.50. Larger sizes, such as are used for pickling-onions, half the above prices. These will also do for planting out in September, but they are more disposed to send up seed-stalks than the smaller ones. White Multiplier and Whittaker onions, large sizes, that will split up into small ones if planted now, quart, 10 cts.; peck, 75 cts.; bushel, \$2.50. Small sizes, that will make large onions next year, quart, 20 cts.; peck, \$1.00; bushel, \$3.50.

At the present price of wheat, over \$1.00 to-day, August 23, I do not know but we could almost afford to grow wheat on our vacant ground for high-pressure gardening. Nice potatoes are also still worth \$1.00 a bushel; apples ditto. Don't let your ground be idle. Get in crimson clover, rye, wheat, onion-sets, or something else. It looks at present as if there were going to be a demand for almost every thing we raise, and at very good prices.

#### POTTED STRAWBERRY-PLANTS WITHOUT THE USE OF POTS.

In connection with this new material, jadoo fiber, we have made a discovery which is, I think, of considerable importance. With the fiber, as I have told you, the pots very soon become filled with roots; and if you are not on hand to slip the pot out, and let the roots expand out into the soil, your plant is injured by becoming pot-bound. Now, my discovery is this: Have a piece of iron turned up in a lathe, so one end is just the shape of the inside of a two-inch pot. Take this iron bar and strike it in the ground after you have pushed the strawberry-runner aside, and you will have a cavity in the soil just like that in a pot. Fill this cavity with moistened jadoo fiber. Push down the runner exactly as if it were in a pot, and then the

plant will never become pot-bound, because the roots will push off into the soil as soon as they have gone all through the jadoo fiber. In a week or ten days, loosen the soil around your plant with a trowel, and then you can lift the plant right out, taking the jadoo fiber along with it. Send it off by mail or express, or plant in your own ground as you please. For use we mix the jadoo fiber in water until it is a sort of mush. You can ladle into the holes in the ground with a large-sized table-spoon. By this means you have no pots to other with, and the plants are never pot-bound, and yet they have fertility enough attached to the roots to give them a nice start in "housekeeping," when they are put out in the field. Very likely some other material or compost might answer as well as the jadoo fiber, but we have never found it. If you want to see what jadoo looks like, just order one of our strawberry-plants by mail, or we can furnish the material at the following prices, which have been fixed by the manufacturers: 5 lbs., 30 cts.; 10 lbs., 50 cts.; 25-lb. box, \$1.10; sack, 120 to 150 lbs., 3 cts. per lb. It may be shipped either from here or Philadelphia, Pa. The material is so light that a single pound goes a good way.

We are prepared to ship promptly by mail or express, charges prepaid, any of the plants mentioned on pages 573, 4, of our issue for August 1.

Below is one of the many reports from one who has tried some of our "new process" strawberry-plants which he received by mail:

The plants arrived in excellent shape, and were set out the same evening. At this writing seven have runners, which I have potted; the other three plants, runners, are just visible. ALBERT M. COLE.  
Providence, R. I. Aug. 19.

#### THE IMPROVED AMERICAN COFFEE-BERRY.

In our price list I have told you that this is something quite different from the soja bean, which it very much resembles. The objection to the soja bean for coffee is that it has a disagreeable flavor of beans or peas. Well, the coffee-berry we had last year had something of this flavor still, which made it objectionable to many people. A short time ago, however, a sample was sent me of a smaller-sized coffee-berry, saying it was a variety that matured so quickly that three crops could be grown in one season in Missouri; and, furthermore, that I would find by test that it was harder to detect from the genuine than anything heretofore offered. This I find true, and, in fact, I should pronounce it excellent coffee. I do not think I could tell one from the other—or, at least, the coffee-berry would be fully as pleasant and agreeable to me as the genuine coffee. I have obtained coffee berries from different seedsmen, and we are growing them in our test-grounds. There are at least half a dozen different kinds. I was, however, so well pleased with this latter small kind that matures so quickly I at once made a purchase of two bushels like the sample, and we shall offer only this for sale, throwing away the kind we sent out last season. I am sorry for this; but the new smaller seed is so great an improvement that it will pay us all to do this. As to whether it is equal to real coffee or not, I think you had better all decide the matter for yourselves, and you can easily do it with a five-cent package. The price of the improved quick-growing coffee-berry is 10 cts. per ½ pint; 15 cts.; quart, 25 cts.; peck, \$1.75. If wanted by mail, add 10 cts. per quart extra for packing and postage.

#### KIND WORDS FROM OUR CUSTOMERS.

Every time I order goods I am more and more pleased. Next year I intend to purchase more foundation, and use it entire in boxes, and also in some frames. XAVIER PICQUET.  
Sainte Marie, Ills., July 27.

The foundation is wonderful, and it is hardly possible to believe it was made by machinery. I hope you will send me the strips soon. H. J. BROMWICH.  
Angola, Erie Co., N. Y.

I had no income from my bees from 1883 until this year, and even now the drouth has ruined my berry crop. But the fact is, I can not afford to part company with a man who has such a real love for turnips. Beloit, Wis., Aug. 4, 1897. P. E. MARSTON.

The samples of drawn comb are at hand. Thanks. I am much pleased with their appearance, and can see no reason why this article should not prove to be all you claim for it. B. WALKER.  
Ewart, Mich., July 31, 1897.

Your brood foundation and starters for sections, shipped June 2, are of excellent quality, and cut to good advantage. Goods received all right. Thanks to the A. I. Root Co. ALFRED JACKSON.  
Jackson, Ohio, June 22.

Since I have been in the bee business I have bought over \$100 worth of goods from you for myself and others, and I have always found your goods to be the best and cheapest in the long run. JOE C. MOORE.  
Globe, N. C., June 14.

The queen came to me the 17th of May in good condition, and is a perfect beauty. She has to-day, June 26, the hive full of beautiful Italian bees, and I am well pleased. A. BARNEY.  
Seattle, Wash., June 26.

The goods I ordered this spring came to hand in due time, and are very satisfactory. The extra-thin surplus foundation is very fine. The bees take to it promptly. The Cornell smoker is just *boss of the bees*. The cream sections are also very good. Please accept thanks. GREEN R. SHIRER.  
Green, Iowa, June 26.

Mr. Root—I wrote you, night before last, that I had received the strawberry-plants, and to-day I received a statement and ten cents in stamps. You certainly conduct your business honestly, and give every one his due. I did not expect you to take all that trouble to return that little, and, in fact, did not know that I had sent too much. The plants are growing right along; have never drooped, and two of them are putting out runners. JOE L. COOPER.  
Nashville, Tenn., July 17.

I am a young bee-keeper, and am desirous of trying the new foundation, so I have ordered a small sample. My year's supplies, ordered from your branch office at Mechanic Falls, I think the best I have seen. The Weed foundation is perfection. I wish I could afford to use full sheets on every frame in my new hives.

I must say a good word for GLEANINGS. I read every word in it, and wish there were more. In practical hints it has been worth more than \$5 since I began to read it. EMERY D. BICKMORE.  
Stockton Spring, Me., June 7.

## 25 Cts. PER YEAR!

for the best agricultural and stock-breeders' paper published,

**Stuart's Agriculturist.**

Agents wanted! Bicycles, etc., free. Address

**WHITWORTH BROS.,**

Printers & Pub's, 60 High St., Cleveland, O.

Please mention this paper.

**WANTED.**—To sell 100 colonies of bees; ten-frame simplicity hives, mostly wired frames, combs all built on foundation, equipped for comb and extracted honey, every thing fixed for migratory work, can load 30 hives on rack and go any time, every thing on the most modern improved A. I. Root plan, well put up and painted. Bees scarce around here. White clover enough for 5000 colonies. Best of range for out-apiary. I have got to sell on account of climate.

E. Sandford & Son, Nokomis, Ill.

**Queens.**

Untested queens, 50c each; tested, 75c; Breeders, \$2. Either leather or golden. My golden breeders breed all 5-banded bees.

W. H. LAWS, - Lavaca, Ark.

## Central Pennsylvania Bee-keepers!

Buy Root's supplies near home at catalog prices. Observatory hives, winter cases, etc. Also send for catalogs.  
**Prothro & Arnold, Du Bois, Pa.**

Golden,  
Adel,  
Albino.

## Texas Queens.

Dr. Gallup says they are the best he has in his yard.

J. D. GIVENS, Lisbon, Texas.

## GERMAN CARP WANTED.

1000 this year's; 100 or more last year's. Prices must be reasonable. Send offers to  
DR. W. M. MOERSHEL, Homestead, Iowa.  
Carp to be shipped in August or September.

**Italian Queens**, either golden beauties or 3-banded imported stock. Tested, 90c each; untested, 55c each; 6 for \$3.00. One sample queen to new customer, 50c; breeders, \$2.00 to \$3.50 each. P. O. M. O. office, Lavaca.  
E. A. SEELEY, Bloomer, Ark.

## No cheap Queens to sell; but the best.

Golden 5 band, or 3 band from imported mother. Untested, 75 cts.; tested, \$1.00.

L. BEAUCHAMP, Box 613, San Antonio, Texas.

**QUEENS.** I have 500 untested, 3 or 5 banders, 45c each; tested 3-banders, 70c each. They are fine large queens, and are free from all diseases. Write for wholesale prices. M. O. office.  
DANIEL WURTH, Falmouth, Rush Co., Ind.

WALTER S. POWDER'S AD.

162 Mass. Ave., Indianapolis, Ind.

## Fifty Cents Each.

Tested  
Adel  
Queens.

My new (1897) book on queen-rearing, giving a method for rearing queens in a brood-chamber while the queen is present, will be mailed free to all who purchase queens.

Henry Alley, - Wenham, Mass.

## THE A. I. ROOT CO'S Shipping-cases for Honey,

AT THEIR PRICES—THE FINEST MADE.  
CASH FOR BEESWAX

M. H. HUNT, Bell Branch, Mich.

## QUEENS BY RETURN MAIL.

Daughters of best imported queen mother, warrantably purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer, as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded.

L. H. ROBEY, Worthington, W. Va.

**FOR SALE**—15 colonies of hybrid bees in simplicity hives, \$2.50 each. They must be sold.  
E. D. BARTON, East Hampton, Conn.

**WARRANTED** Three and Five Banded Italian Queens at 50 Cents each.  
GEO. W. COOK, Spring Hill, Kan.

**FOR SALE**—Italian queens, 50 cents each.  
MRS. A. A. SIMPSON, Swarts, Greene Co., Pa.

**FOR SALE**—100 colonies of Italian bees and fixtures, and honey crop in a never-failing locality, at a bargain. Address  
LOUIS WERNER,  
Edwardsville, Ill.

**SWEET-LOVER SEED** in the hull, raised this season, 1897, at 4 cts. per pound. Address  
JOSEPH SHAW, Box 64, Strong City, Kan.

## Dovetailed Hives,

Sections, Extractors, Smokers, and every thing a bee-keeper wants. **Honest goods at close honest prices.** 60-page catalogue free.

J. M. JENKINS, Wetumpka, Ala.

## Don't Neglect Your Bees.

Bee-keeping may be made uniformly successful by judicious feeding. It is just as important with bees as with other stock.

Success in feeding depends very much on the feeder used. When you have tried the

## Boardman Atmospheric Entrance-feeder

you will be convinced of this. For descriptive circulars and price list, address

H. R. BOARDMAN, East Townsend, Ohio.

## Wants and Exchange Department.

**WANTED.**—To exchange 16-section non-drip cases at Root's prices, laid down at your station, for fancy comb honey at prices to suit the times. Also second-hand 60-lb. cans, 2 in a case, valued at 25 cts. per can, freight paid, for gilt-edged extracted honey. Special price on quantity lots.

B. WALKER, Evart, Mich.

**WANTED.**—To exchange Parker shotgun (new) for high-grade bicycle, organ, or best offers.

R. A. PROVINS, Point Marion, Pa.

**WANTED.**—To exchange some fine collie shepherd pups for any thing useful. I also have some fine pigeons and a fine blood-hound pup to trade.

CLAUD BRILLHART, Oakwood, Paulding Co., Ohio.

**WANTED.**—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules.

ANTHONY OPP, Helena, Ark.

**WANTED.**—To exchange first-class incubator for comb or extracted honey, potatoes, or offers.

F. W. DEAN, New Milford, Pa.

**WANTED.**—To exchange a Burkard auditorium-size guitar, in good order, for bees, bee-keepers' supplies, or bicycle.

W. A. PREIFER, Mauston, Wis.

**WANTED.**—A second-hand heater for greenhouse. Hitches preferred. Capacity No. 3 or 4.

R. GAMMON, Rockton, Winnebago Co., Ill.

## Black and Hybrid Queens for Sale.

Young hybrid queens, 15 cts., and mismated, 25 cts.  
C. G. FENN, Washington, Conn.

A few hybrid queens from natural swarms, by return mail, at 25 cts. each.  
W. A. SANDERS,  
Elberton, Elbert Co., Ga.

About two dozen nice mismated Italian queens for sale at 25c each, or 5 for \$1.00. They are all young and prolific, and bred from first-class mothers.

W. F. STUART, Box 415, Ottawa, Kan.

**THE S. & H. CO.**

desire to enter into correspondence with all contemplating the purchase of anything in their line. They think they have one of the most complete assortments of strong, smooth, healthy,

## FRUIT AND ORNAMENTAL TREES

Small Fruits, Vines, Shrubs, Roses, Bulbs, Hardy Herbaceous Plants, Greenhouse Stock, Etc., on the market and invite all buyers to come and see for themselves. Honey Column.

CITY MARKETS.

NEW YORK.—We quote you the market this day, subject to fluctuations, as follows: Fancy 1-lb. sections clover comb honey, 12½@13; No. 1 white, same, 11@12; No. 2 white, same, 10; mixed white, same, 9; fancy buckwheat, 9@10; No. 1, 9; No. 2, 8; 2-lb. sections, 1½@2 cts. less per lb., as to quality. White extracted clover, 5½@6; basswood, 5@5½; light amber basswood, 4½@5; amber and mixed, 4@4½; buckwheat, 4. Beeswax, fancy, 28; average, 26@26½. On account of the continued warm weather the demand for comb honey is rather light, but expect as soon as we get a little cooler weather to see an improvement. Notwithstanding the warmth, we have had quite a number of small lots of new comb honey, and they found ready sale on account of the market being quite bare, old comb honey being cleaned up pretty well. The prices rule about the same as last season, and do not anticipate any better prices, on account of the good crop that California produced this year. CHAS. ISRAEL & BROS., Sept. 8. 480-490 Canal St., New York City.

DENVER.—We find our honey trade improving since the first of the month, especially with extracted. Comb honey was never known to sell as low as it is now, and it is the farmers and small bee-keepers that have ruined the price by selling to the stores at any price they were offered. The highest possible price we can quote fancy white comb honey is 10c; and No. 1 white at 9c; No. 1 white extracted, 4½@5; good clean beeswax, 25. R. K. & J. C. FRISBEE, Sept. 6. Lock box 1014, Denver, Col.

MILWAUKEE.—The receipts of new-crop honey are beginning to come in, and the quality improved. The supply is not equal to the legitimate wants of our trade, and with improved conditions of trade we expect to sell more than last year. The demand so far is not heavy, but we feel, to encourage our shippers, that it will come. We quote white No. 1 comb 1-lb. sections, 11@13; amber, 8@10; white extracted, in bbls. and kegs, choice, 4½@6; dark or amber, in bbls. and kegs, 4@6; beeswax, 25@27. A. V. BISHOP & Co., Sept. 6. Milwaukee, Wis.

CHICAGO.—Comb honey sells a little more freely, yet receipts are in excess of sales, and some shippers' of small lots get impatient at what seems a long delay in getting returns, yet it can't be forced without detriment to general interests. Best grades of white comb bring 12c; white but objectionable, 10@11; amber and dark, 7@9; extracted white, 5@6; amber, 4@5; dark, 3½; beeswax, 25@27. R. A. BURNETT & Co., Sept. 6. 163 South Water St., Chicago, Ill.

CINCINNATI.—Demand is fair for extracted and comb honey, and considerable honey is arriving, but not much more than is justified by the demand. As the range of prices, we quote for choice white comb honey 11@13. Cincinnati is no market for dark comb honey. Extracted sells for 3½@6, according to quality. Beeswax is in good demand at 20@25 for good to choice yellow. CHAS. F. MUTH & SON, Sept. 7. Cincinnati, O.

DETROIT.—Best comb honey, 10@11½; best extracted, 5@5½; beeswax, 25@26. M. H. HUNT, Bell Branch, Mich. Sept. 7.

ALBANY.—New-crop comb honey now arriving, but demand quite limited as yet. We quote fancy white at 12@13; fair to good, 10@11; dark, 8@9. Nothing of any account doing in extracted. No beeswax on hand. CHAS. McCULLOCH & Co., Albany, N. Y. Sept. 7.

NEW YORK.—New-crop comb honey arriving more freely, and demand good. We quote fancy white, 12@13; off grades white, 10@11; buckwheat, 9@10. California extracted selling fairly well, while all other kinds are neglected. We quote California white, 5@5½; light amber, 4½@5; Southern, 5@5½ per gallon; beeswax dull, and easy at 26. HILDRETT BROS. & SEGELKEN, 120-122 W. Broadway, New York. Sept. 7.

COLUMBUS.—Fancy white clover, 12½; No. 1, 11. Arrivals no heavier; demand better, but no improvement in prices. Large sales are impossible, and as yet are having no trade from near-by towns. THE COLUMBUS COMMISSION & STORAGE Co., Sept. 6. 409-413 N. High St., Columbus, O.

BOSTON.—We quote you our honey market as follows: Fancy white comb in 1-lb. sections, 14; No. 1, 12@13; white extracted, 7; light amber extracted, 5@6; beeswax, very light supply, 27. Good demand. BLAKE, SCOTT & LEE, Boston, Mass. Sept. 7.

KANSAS CITY.—We quote No. 1 white comb, 11@12; fancy amber, 10@11; No. 1 amber, 9@10; fancy dark, 8@9; No. 1 dark, 8; white extracted, 5½@6; amber, 4½@5; dark, 4@4½; beeswax, 22@25. C. C. CLEMONS & Co., Kansas City, Mo. Sept. 7.

MINNEAPOLIS.—No. 1 remains same—no change, 11@12. Other grades accordingly. Supply equal to demand. S. H. HALL & Co., Minneapolis, Minn. Sept. 6.

ST. LOUIS.—We have no special remarks to make in regard to the honey market. Prices are nominal at last quotation. Weather is too hot for the sale of honey. Beeswax is a little firmer, being 24½@25 for prime stock. WESTCOTT COMMISSION Co., 213 Market St., St. Louis, Mo. Sept. 9.

CLEVELAND.—We quote selling to-day as follows: Fancy white, 13; No. 1 white, 11@12; fancy amber, 10; No. 1 amber, 8@9; buckwheat, 6; fancy white extracted, 6½; beeswax, 25. A. B. WILLIAMS & Co., Sept. 8. 80-82 Broadway, Cleveland, Ohio.

PHILADELPHIA.—Honey coming in freely, and some call for comb, but the hot weather of the last few days stops sales somewhat. We quote fancy white comb 13½; No. 1 white, 11@12; no dark comb in yet; white extracted, 5½@6; amber, 4@5; beeswax, 25. We are producers of honey; do not handle on commission. WM. A. SELSER, 10 Vine St., Philadelphia, Pa. Sept. 7.

FOR SALE.—25 bbls. extracted pure white-clover honey, very light in color, and of finest quality, at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired. EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—A lot of good extracted clover honey in 60-lb. cans. JNO. A. THORNTON, Lima, Ills.

WANTED.—To buy quantity lots of fancy comb honey in non-drip cases. E. WALKER, Ewart, Mich.

FOR SALE.—Alfalfa honey, light amber, in carload lots. 3½ cts. per lb.; sample, 10 cts. JOHN NIPPERT, Box 1061, Phoenix, Arizona.

FOR SALE.—5000 lbs. extracted white-clover honey; water-white and good body, in packages to suit customers. Cheap for cash. J. B. MURRAY, Ada, O.

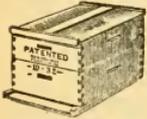

FOR SALE.—Pure honey.—Clover, extracted, 6½ cts. per lb. Buckwheat, extracted, 4½ cts. per lb. I. J. STRINGHAM, 105 Park Place, N. Y. City.

**SWEET-CLOVER SEED** in the hull, raised this season, 1897, at 4 cts. per pound. Address JOSEPH SHAW, Box 64, Strong City, Kan.

# A Tested Queen and the Review for \$1.50.

I have a large number of nuclei containing fine tested Italian queens of this year's rearing, and have decided to use them in helping to build up the circulation of the **Review**; hence offer a queen and the **Review** one year to *new* subscribers for only \$1.50. **Review** alone, \$1.00; queen alone, \$1.00. If several queens are wanted, write, and the price will be made according to the number. As a rule, orders are filled by return mail, and there is never a delay of more than three or four days, and that on large orders.

W. Z. HUTCHINSON, Flint, Mich.

## \$100

Given as **BOUNTIES** to purchasers of the improved Danz. Hives and Sections. For particulars see p. 64, of my book, "**Facts about Bees.**" Sent Free for 2-  
 □ stamp. Address  
**F. DANZENBAKER, Washington, D. C.**

**Italian Queens**, either golden beauties or 3-banded imported stock. Tested, 75c each; untested, 50c each; select tested, \$1.00 each; breeders that produce pure stock, of either variety, \$2.00 each. P. O. M. O. office, Lavaca. **E. A. SEELEY, Bloomer, Ark.**

Philadelphia Office of

**THE A. I. ROOT CO.,**  
 10 Vine St., Philadelphia, Penn.

Now is the time to order

**Shipping - cases, Winter Cases, Chaff Division-boards, etc., etc.**

Order from catalog; prices are same as from factory.

## Shipping=cases.

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA.** Immense stock. All orders for cases or other goods shipped by return freight now. Address

**JOS. NYSEWANDER, Des Moines, Iowa.**

### PRICES OF

### Bingham Perfect Bee-smokers and Honey-knives.

|  |                                     |

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer I write for a circular. I do not think the 4-inch Smoke Engine too large.  
 January 27, 1897. Truly, W. H. EAGERTY, Cuba, Kansas.

**T. F. BINGHAM, Farwell, Michigan.**

## 4 Months' Trial Trip for 25c.

The weekly **American Bee Journal** would be a great help to you in your work with the bees. Better have it the last four months of 1897 for only 25 cents, if you are not already a subscriber.

The **Buffalo Convention Report** will be published in the *Bee Journal* in full, right after the meeting, beginning early in September. That report alone will be worth many times the 25 cts. Send for free sample copy, anyway. Address

**GEO. W. YORK & CO., 118 Michigan St., Chicago, Ill.**

VOL. XXV.

SEPT. 15, 1897.

No. 18.

## STRAY STRAWS

FROM DR. C. C. MILLER.

A BY-LAW of the Central Texas Association reads, "All white persons interested in apiculture are eligible to membership in this Association."

FOUR APIARIES are reported in *American Bee Journal* by Prof. Cook, aggregating 1535 colonies, and yielding 90 tons—an average of 117 lbs. a colony.

SWEET-CLOVER ointment. "A handful of sweet-clover leaves fried in about half a tea-cupful of fresh lard or hen's oil."—*Mrs. Lambrigger, in American Bee Journal.*

APIS DORSATA was discussed at Buffalo, and I didn't have a chance to say a word against it—was temporarily in the chair. Wonder if that was a put-up job between Pres. York and the dorsata men. [See editorials.—ED.]

THE SOCIAL PART of the Buffalo convention was probably better than any of its predecessors. It was worth going a long way to meet some of the men that were there. Some grand good men are in the ranks of bee-keepers. [Just so.—ED.]

AN UNPRECEDENTEDLY heavy honey-flow is given, p. 636, as a possible reason for excessive swarming. Wouldn't it be better to substitute "long" for "heavy"? We are generally told that bees swarm more in a moderate than in a heavy flow. [In answer to your question I would say "I don't know."—ED.]

F. L. THOMPSON, p. 629, wants me put out because I don't want the bother and worry of making my own foundation. Now see here, F. L., just you have that little scheme carried out, and the first thing you know some other fellow will want you put out because you don't want the bother of making your own sections.

RETURNED SWARMS, we are told on p. 636, "will swarm as often as you hive them, and as long as the honey season continues." That may do for a rough statement, and even for an exact statement, providing the season closes about two weeks after the first swarm, for in two or three weeks the last young queen

will have emerged and the swarming will be over. [I meant the statement in question to apply in a general way. I accept your emendation.—ED.]

EARL C. WALKER, p. 625, says that, in transferring, there should not be a tight fit between hive and driving-box. That agrees with views held across the water, and foreign journals have had pictures of transferring in which the driving-box rested on the hive at an angle of nearly 45°, so the queen could be seen when she went up.

PROF. COOK, p. 622, says he voted against amalgamation, not because he was opposed to it, but because he thought the change should not be forced upon those opposed to it. If others did the same way, it can easily be understood that amalgamation would fail with a large majority in its favor. But, say, professor, how about forcing upon us who did want the change, something we didn't want?

PREVENTION of after-swarms, H. W. Savage says he accomplishes (*American Bee Journal*) by hiving swarm on old stand, putting supers over excluder, then setting old hive on top. "The afternoon of the second day, the old colony will become so depleted of bees (if the weather has been favorable) that they will give up swarming any more, and will begin to carry out drone brood. Then carry them to a new stand."

FRENCH BEE-KEEPERS are in the throes of a discussion as to uniformity in size of frames. A frame 30 by 40 centimeters (11 $\frac{3}{8}$  by 15 $\frac{3}{4}$  inches is likely to win; but that's inside measure, and it is wisely argued that there can be no exact uniformity without a settled outside measure. That would be something like 16.3 by 12.3 in., making a capacity about 28 per cent larger than the Langstroth-Simplicity. The British standard, 14 by 8 $\frac{1}{2}$ , is about  $\frac{3}{4}$  as large as the Simplicity. [The French are believers in large frames. They follow Dadant, you know.—ED.]

PROF. COOK has been sampling with others some sage honey, "and all with one accord have pronounced it the best honey they have ever eaten."—*American Bee Journal.* Additional proof that locality rules taste. Sage is best to the Californian, clover to the Northerner, eucalyptus to the Australian. And it

seems further, that, when a man changes his locality, he changes his taste. [In York State very many greatly prefer buckwheat to any white honey produced. Nine-tenths of all buckwheat is produced in York State. As you say, locality rules taste.—ED.]

DOOLITTLE says, p. 635, that nearly all of our best bee-keepers agree that Italians are not inferior to blacks for comb honey. I think that's correct, and I wonder whether those who insist that Italians seal comb with a watery look have a special strain. I've had several strains of Italians, but they all make nice white combs. [I have seen lately a good deal of comb honey made by black bees. To my notion it is just a *little* whiter than that made by the average Italians. In *quality* produced they (the Italians) are certainly not inferior. Doolittle told me he had a strain of *yellow* Italians that cap just as white as black bees.—ED.]

TRAVEL-STAINED SECTIONS are not good to sell—only to eat. The editor prefers them for his eating, and perhaps all do who know enough. Would it not be worth while to take some pains to educate the public in this regard? Even where looks count for every thing, it's just as well to have only one side white, for the other side is not seen after the honey is placed on the table. [If the consumer could sample comb honey by *taste* rather than by the *eye* before buying, the travel-stained honey would soon work its way to the front. I bought some large California pears that looked, oh! so nice! but when I came to eat them they tasted like insipid pumpkins. I then wished I had bought home-grown Bartletts that looked inferior. I am educated on the pear question.—ED.]

QUITE A PRETTY FIGHT that has been between F. L. Thompson and the editor about the Rietsche press. Although it may never be settled without arbitration, the discussion has brought out some important points interesting to all. In spite of the evident desire for fairness, there crops out occasional prejudice on both sides. Thompson hardly wants to see that bee-keepers have largely given up making *brood* foundation, and ye editor insists that a Rietsche press must be saddled with express charges from Germany. If he believed with Thompson, the presses would be made in this country, and at any rate they could come from Germany by freight. [This one item of express charges was only a small part of the whole matter. The principal item was the great difference in *quality* of the two foundations.—ED.]

---

#### BREEDING FOR LONGER TONGUES.

BY PROF. A. J. COOK.

The following inquiry appeared on p. 462, current volume of the *American Bee Journal*: "Do you suppose it possible to increase the size—and especially the length of tongue—of the races of bees we now have? If possible, do you think it desirable?" I was very much

surprised to find that seven answers implied doubt or impossibility regarding the first part of the questions. The majority, however, and they the leaders in our ranks, like Elwood, R. L. Taylor, Dr. Mason, and the Dadants, give an emphatic "Yes." My own answer was this: "Yes, I have no doubt of it, and I believe it is desirable." I believe that scientific research abundantly warrants us in giving a positive categorical answer to this question, in accord with the majority. I wish briefly to give my reasons not only to inform those who may not have had time or opportunity to study in such lines, but also in the hope of influencing some one to undertake a line of work full of promise to apiculture.

When Schwann discovered that the cell was the basis of all tissue, whether animal or vegetable, and that the animal and vegetable cells are essentially alike, he made a discovery of great practical importance. Of hardly less value was the discovery of the law of the "conservation of energy." Darwin's researches proved that the laws of breeding of animals and plants are essentially the same. Every breeder of plants and animals to-day recognizes and acts upon this truth. We know now of a truth that all organisms, plant and animal alike, tend to vary. We also know that close breeding in the line of any special variation tends to make that variation more prominent, and at the same time to fix it. Thus, such men as Bates, Boothe, the Collens brothers, and Bakewell, gave us our short-horns and improved sheep. In like manner our wondrous Hamiltonians and marvelously modified breeds of swine have been developed in a single generation. What is true of our higher vertebrates is certainly true of insects. True, some animals tend to vary more than others, and probably the characteristics of some would be more quickly set by careful selection than others. But that all are subject to these laws, and would respond to their action, there can be no shade of doubt. That our bees, and especially the highly wrought and sensitive Italians, whose tongues have been already pushed out two one-hundredths of an inch longer than those of the black races, and that by the slow process of "natural selection," would be quick to vary and as quick to respond to the more severe artificial selection, seems to me more than probable. Two or three of the answers referred to, express belief that, "while it is possible to breed longer tongues, it is not practicable;" but I see no reason to hold such a view.

What is needed to succeed in this work is a man of great patience, quick observation, determined will, and absolute accuracy and honesty. It will take long years, hence the necessity of great patience. Slight variations must be detected, and used in the selection of breeding-stock; therefore close powers of observation are called for. Often the hardest effort will seem to advance the undertaking but little, and possibly none at all; yet this must not breed discouragement, and thus the necessity for a determined will. The best men are likely to be biased in judgment when they are seeking some valuable end, and

therefore the vision of the breeder must be clear and true.

#### THE METHOD.

A good tongue-gauge, accurate knowledge of the habits of bees, and good judgment to use this knowledge, and unflinching persistence—even in the face of seeming failure—are the implements that shall win in this struggle. The inclined-plane tongue-gauge used by me some years ago, and which won a medal at the Paris exhibition, is cheap and effective. Simply placed in the hives it will tell what colonies have longer tongues than others, and so what colonies should be used in breeding. Mr. J. H. Martin and others have also invented efficient and practical gauges by which the length of the tongues could be accurately measured. When colonies are found that show that the workers have tongues longer, even though but slightly so, than the average, the queens of such colonies should be used exclusively in breeding. If by use of any of the methods recommended for controlling mating as to male or drone bees, as by pruning drone comb, using drone-traps, securing early drones from desired colonies, or by working in isolated districts, both drone and queen can be selected; then the end sought would be brought nearer. In case the apiary were large, so that a large number of queens would be needed, then more speedy results might be expected. The tongue-gauge would surely tell which of the new colonies had retained or increased the desirable feature, and so which to use in subsequent mating or breeding.

Such an effort, intelligently and faithfully persisted in and carried out, would surely result in a greatly improved race of bees, and in as great advantage to our craft. The only question is, Have we the man with the required patience and persistence? This would be, in some ways, much easier than improving cattle, horses, and hogs, as the numbers produced per season would be immensely greater, though the greater difficulty in controlling mating would stand in the way of quick results. Who has the patience to do this valuable work?

#### NOTES.

One bee-keeper in San Diego Co., near Escondido, is reported to have shipped six carloads of honey this season. B. S. Taylor, of Perris, started with 154 colonies of bees, and has increased to nearly 200. He has taken ten tons of first-class extracted honey, and 6000 sections of fine comb. I have tested the latter, and never tasted finer. This has been a fine season in Southern California.

I was glad to read the Michigan foul-brood law in last GLEANINGS, and to note your and Mr. Hilton's kind words; for it was I who wrote the bill and secured its passage. Mr. Root, who had charge of the bill, was at one time a successful bee-keeper of Mason, Mich., and I think he was mayor of his city.

You seem to express doubt of the position that poisonous plants would not, as a consequence, secrete poisonous nectar. The plant is poisonous because the sap or tissue contains

some toxic element. The nectar is secreted by glands which take elements from the sap, and form from these the sweet of the flower. The nectar is not the sap. The nectar is to attract insects to pollinate the flowers. Were it poisonous it would defeat its very purpose. Therefore reason, and, so far as I have been able to discover, observations as well, argue that nectar, even of poisonous plants, is non-poisonous. Honey, when eaten immoderately, or at all in rare cases, makes some people very ill. In the region of known poisonous plants, how easy to start a story of poisonous honey from such plants, and yet such story be utterly without truth! If the story dated back to Xenophon's time, how much more unworthy of credence! for scientific accuracy is much more common to-day.

It grieves me to the heart that our grand old friend Dr. Mason disagrees with me. It is pleasant to be in accord with such men, and sad that they should be in the wrong (?). I have only to say that I do not believe both Unions will survive. I do not think that there is room for both. I did not say we should resist the expressed wish of the members. I was in doubt. To save its life might warrant such a course. That is what advisory boards are for—to act in an emergency. I am firmly of the opinion that the two Unions should be merged into one; and it begins to be very clear to me which one will survive. In this opinion I wish to blame or impugn the motives of no one. I see no reason to accuse any one of acting in any way other than what he believes wise and right.

Claremont, Cal., Aug. 16.

---

#### STRONG COLONIES.

Bees Hanging Out; Wide Entrances; Colorado vs. Wisconsin; the Glorious Climate of the Former; a Valuable Article.

BY M. A. GILL.

*Mr. Editor.*—I was highly interested in your editorial remarks in the Aug. 1st issue on the advantages of big colonies; also in regard to "getting bees started in sections," and to "bees hanging out;" and with your consent I will give to your readers some of my ideas along these same lines.

"Strong colonies" has always been one of my hobbies; and while producing extracted honey in Wisconsin I secured them by using a two-story 8-frame hive for a brood-nest, and was troubled very little with swarming; but since coming to Colorado, and producing comb honey exclusively, I find that, while colonies in 8-frame hives may be a little more prone to swarming, as good results may be obtained with this hive as with any other if the colony is so managed that the 8-frame hives are used for breeding, instead of for storing surplus.

I find that, early in the spring, the queens (none but prolific ones are allowed to live) will stake off and occupy the room they need, and increase the area of brood as the strength

and warmth of the colony require. Then while every condition is on the ascending scale, when the brood is clear up to the top-bars, is just the time to put on the first super, the next super being put on when the same condition is reached again, never allowing the bees to quite reach the zenith of their ambition.

As a proof that there is scarcely any limit to strong colonies so managed I will say that I have five colonies (four of which did not swarm, and one that was made by uniting two first swarms) among my bees, and they are now working in their eighth super, or 40 supers for the five colonies.

In this apiary are 117 colonies, about 40 of which have a 10-frame capacity. Now, isn't it provoking that only one of the five is a 10-framer, and four of them just the common 8-frame Dovetailed hives? But, you know,

comb-builders who will teach them by example that there is something in this world to do.

While traveling among the bee-keepers in the capacity of foul-brood inspector, I am often asked this question: "Gill, why do my bees hang out so?" and upon examination I find the bottoms nailed on tight, and the entrance-blocks turned the long way, and nailed to the entrance, and the hive standing out in the hot sun, with no shade whatever. Why should any sane man ask such a question, under those conditions? Why, I had rather set a hive up on stilts, and take the bottom clear off; and I sometimes do, for I go after my bees with mighty heroic treatment sometimes in order to break up these habits, for bees are not unlike us men who know it is very hard to leave off ruinous and bad habits when once they are well formed.

M. A. GILL IN HIS APIARY IN COLORADO.

Josh Billings said, "Never argy agin success," so I won't; but you may if you want to.

But if a colony gets a lot of sealed honey between the brood and top-bars, and gets the corners and sides of the hive well stored with sealed honey, and has been given so small an entrance that it has *compelled* them to learn to hang out, you may put on supers, give bait sections, uncap honey, etc., but they won't prosper. You know Billings said, "If a man gets a start down hill, it seems as if the whole world is greased for the occasion;" and the colony mentioned above seems to be in the same condition, although Nature's storehouse is running over with sweetness. The only way I can successfully break the habit is to exchange this colony's super for one from a colony that has a super well occupied with

Other people say to me, "I wish you would tell me why my bees *won't* go into the supers;" and on inquiry I find that a colony in an 8-frame hive has been allowed to swarm perhaps three times; the first swarm has been allowed to get into that clogged condition above mentioned, the parent colony has not yet rallied from the drain upon it, and the other two swarms are not yet strong enough to go above. As Edwin Bevens says in the last issue of the *American Bee Journal*, "Another fool question. Why do people expect bees to occupy supers until the conditions in the brood-nest and the strength of the colony warrant it?" All such men should follow the advice of Moses Quinby, when he says, "Confine your experience to pecks of bees instead of pints." Years ago I did a great deal of dividing, but

must say that doubling up gives me more satisfaction.

I will give you a glimpse of one end of my Crescent Apiary, situated away over on this side of the Rockies, on the border of the desert. You will notice at my back, out through the timber, a growth about as high as a man's shoulders, and in full bloom. It is cleome, or the so-called Rocky Mountain beeblossom, of which there are acres and acres made to grow by the sub-irrigation from Grand River, that flows only about 20 rods to the right of the picture.

On the left, out through the opening in the timber, commencing within a quarter of a mile, are the farming and fruit lands, under a fine system of irrigation, among which are hundreds—yes, thousands—of acres of alfalfa!

The bees shown in the picture are doing finely. Another apiary, in the direction of the opening in the timber, and only four miles away, is doing and has done poorly during the entire season, while my other apiary, 117 colonies, out in the foot-hills, 15 miles from here, have increased from 58 to 117, and will give 200 24-lb. cases of comb honey this season. I bought them just at the close of the swarming season, or perhaps there would not have been so many.

To give you an idea of the resources of this valley that has been redeemed from the desert in the last 14 years, I will say that the railroads estimate that there will be shipped from this county 1000 carloads of fruit this season.

While I shall always have a kindly remembrance for old Wisconsin, I have no desire to exchange this glorious climate and my wife's health for the rigors of a Wisconsin winter.

Grand Junction, Colo., Aug. 12.

[I indorse so thoroughly every thing that is said by friend Gill that there is really nothing that I can say by way of comment except to add that the time is coming when honey-producers will soon cry for larger entrances to their hives. We expect to make our hives next year so that the entrances will be an inch deep, and the full width of the hive. A small entrance can't be enlarged; but a large one can be contracted if necessary. Large hives and large entrances capable of contraction will do much to solve the problem of swarming for the future, I believe.—ED.]

#### AMONG THE MICHIGAN BEE-KEEPERS.

Square Bottom-bars; Producers Selling Their Own Honey; Large Hives.

BY A. L. BOYDEN.

While looking over Mr. Morrison's yard I noticed that he used bottom-bars  $\frac{3}{8}$  inch square; but instead of nailing them in in the usual way with a flat side down he places them in with the angle or corner down, giving as his reasons that the bees attach the combs better, and it leaves no space underneath, in case a bar should sag, for moths to hide. It seems to me the  $\frac{3}{8}$ -inch bottom-bars should have a more extended trial, and I am inclined

to think the manner of nailing them in, as used by Mr. Morrison, may be an advantage.

#### BACK TO MR. WING'S APIARY.

Early next morning Mr. H. S. Wheeler drove down to Mr. Morrison's yard, having learned that I was down there. I had planned to go back by Mr. Wing's apiary, and so, bidding adieu to friend Morrison, I loaded my wheel into Mr. W.'s buggy, and started back with him. Not being able then to go to his yard our visit was made mostly as we drove back to Mr. Wing's. Mr. Wheeler uses the Gallup frame, I believe, working entirely for comb honey. Knowing of a sale he made of part of his crop in August, 1896, at 12½ cents per lb., I mentioned that it was a fortunate deal, for many sold at much less only a few weeks later. He surprised me by saying he received more for the rest of his crop than he did for the lot I spoke of. Instead of selling his honey outright to some large concern, or sending to a commission house, Mr. Wheeler has sold largely to grocers and large consumers direct, or through some one employed by him, mainly in cities outside of the great honey-producing district. It certainly would pay the average bee-keeper to spend more of his own time in selling direct to grocers and consumers.

Before reaching Mr. Wing's yard we met Mr. Wing himself. Turning about he drove back with us to his yard. Mr. Wheeler soon left us, and then we went out to examine some of the supers. No doubt, to the bee-keepers of that section the season has seemed a failure when compared with previous years; but by the appearance of the supers in Mr. Wing's yard I should say he has taken a better crop this year than the average bee-keeper of Southern Michigan has for a number of years. To one who has ever had the "bee fever" the incidents related by these men regarding the wonderful flow from willow-herb in former years are very interesting indeed. While they were somewhat discouraged, I felt much of my former enthusiasm coming back.

Near by is the yard of E. S. Frost, where I also stopped; but I failed to see him there or at his home, some six miles south.

I next wheeled over to Breckenridge, where a number of bee-keepers are located, and was soon at the home of N. E. Doane. Not many years ago Mr. Doane located here with a small apiary. His remarkable success led a good many to enter the field, so large numbers of bees are kept in that section. Very naturally, his neighbors have come to him for hives, and this year he has handled nearly a carload of supplies.

Readers of GLEANINGS will remember that The A. I. Root Co. has been, the past year, supplying foundation without paper, when desired. Mr. Doane, as well as his wife, who assists him a great deal in his work, very much prefers foundation without paper, as it saves so much time, and the foundation has invariably reached them in good order without paper.

#### LARGE HIVES.

Mr. Doane is amused by any discussion as to the merits of eight-frame versus ten-frame

hives. He calls them both *small*, and a visit to his yard shows a large number of *twelve* and *sixteen* frame bodies. I can not explain his system here, but it seems to have some decided advantages. He says: "It's the honey I am working for," and I should think he gets it too.

From his place I went to Saginaw, expecting to visit one or two bee-keepers there, but failed to see them. I therefore started homeward, feeling well repaid for my visit to the willow-herbers.

---

#### AUSTRALIAN LUCERNE HONEY, AGAIN.

BY E. TIPPER.

*Mr. Editor:*—When, on May 15, 1896, I innocently penned those few fraternal lines to you containing a few items of local bee-news, I little thought I was laying myself open to such monstrous charges as appeared in your issue of May 1st of this year, from Michael Scobie. Notwithstanding your quite sufficient reply, I, being accused of "abuse" and "slander," feel I must reply.

I spoke of the lucerne, or alfalfa, because there had been some discussion in your journal then about alfalfa honey. In the month of March, 1893 (our autumn), a flood of a magnitude not known for at least some seventy years, swept the valley of the Hunter clean. It was not till the following August (our spring) lucerne could be planted; so in the summer following (1894-'95), the lucerne being young, there was very little honey from that source. The following season (1895-'96), and of which I wrote to you (my letter being dated May 15th of that year), the lucerne gave a good flow of honey, but, as I have stated, it was thin. We will now go back.

My place of business is in the most central part of West Maitland — right in the heart of this lucerne-growing district. In 1893 I added to it a honey-depot. Through the flood alluded to, no honey came for my bees. I purchased honey from the interior, and worked up a good trade. In 1895-'96 I gathered a few hundred pounds from my own bees (lucerne honey); also bought locally from several of the best-known local apiarists, including sections from Mr. Munday. But it was, as I have stated, all *thin*. My customers complained, and the trade was falling off. I tried to thicken it by leaving it in an upper room under an iron roof, but without avail. While in Sydney I mentioned the matter to a bee-scientist, who replied that lucerne is a clover, and all clovers yield thin honey. Strange at our local show that year, honey (said to be lucerne) of a density much greater than my experience had found it, gained prizes. The members of my family and I examined it. We said and say nothing. As I am in no way connected with any supply or queen-rearing business, but must keep bees or cease to be editor of the *Australian Bee Bulletin*, I removed my apiary some 125 miles away from Maitland, to be among the flowers whose hon-

ey I found to be in most demand among my customers, leaving my sons to manage my business.

This year there has been a great lucerne flow on the Hunter. Up to the present I have not tasted the honey; but at the Musselbrook show, some six weeks ago, I was shown some nice-flavored dense honey which I was told was lucerne honey from Maitland. The conclusion I had to arrive at was that the lucerne yields thin honey the two first years after it is planted. Then, as Mr. Scobie says, as the plants become strong and deep-rooted, the honey becomes more dense. This may be a very important bit of knowledge gained, that may come in very useful to many an apiarist, and who may thus become indebted to Mr. Scobie for attacking me and thus bringing it out. I have no wish, no interest, no desire, to disparage lucerne honey. My home, my children, and what I have worked for for years, are at West Maitland, the center of the Hunter Valley, and I intend starting another apiary there in the spring. I feel sure that all who read the short remarks I made will say it was done in the spirit of truth.

Maitland, N. S. W., June 26.

---

#### POISONOUS HONEY.

BY T. C. POTTER.

*Mr. Root:*—I inclose you quite a formal and exhaustive treatment of the question of poisonous honey, which I cut from the August, 1896, number of the *American Druggist and Pharmaceutical Record*. You may have seen it; but as it goes into the subject so far, referring even to ancient classical authorities, I thought you might prize it and be glad to copy it in GLEANINGS, or at least file it away among your references for discussions upon this subject, which, like the ghost, never downs.

Indianapolis, Ind., July 3.

[Just as I was getting ready to start for the Buffalo convention the above came to hand. As I have not space to print all of the article in question, nor time to condense it, I have asked our stenographer, "W. P. R.," to do the latter. It is an important matter, and is worthy of all the space it takes.—ED.]

The article in question is by Mr. Lyman F. Kebler, Ph. C., B. S., Philadelphia. It is, I believe, one of the fullest and most comprehensive reviews of the subject we have. While space forbids a reprint of the whole article, I will mention some of its points.

Mr. Kebler tells the familiar story of the trouble Xenophon's soldiers had with unwholesome honey; also similar quotations from Strabo, Pliny, and others, to the same effect. Nearly all the references to poisonous honey point to Asia Minor as being the home of the plants producing it. He says that at Abaza, near the Black Sea, 25 tons of "mad honey" is gathered annually for shipment, to be added to intoxicating liquors in order to increase their effect. Perhaps this suggests

"Jersey lightning" to the writer, for he immediately says that not less than eight cases were reported in New Jersey last year (1895). In one case the poisoning was on a wholesale scale, fourteen being affected, six of them severely. None died. At Branchville, S. C., twenty persons were affected, three fatally.

In speaking of the Princeton poisoning, the writer says:

The sections of comb honey in the writer's hands were carefully examined externally, and found to possess a normal physical appearance. One section would not have aroused the least suspicion in odor, color, or taste; but another section was quite dark, reddish brown, possessed a nauseating odor and a pungent, burning taste in the back of the mouth and throat, in a measure resembling the first sensations of aconite. A number of persons were invited to take a little of the honey, its character being unknown to them; all immediately began to cough, and question the quality of the product. A third section was entirely eaten by the writer and another person in a day and a half with no ill effects. A small portion of one side of the comb possessed a most pleasant flavor, while the remainder faintly resembled section two above. The producer was not certain that all of the sections delivered to the writer were poisonous.

Mr. Kebler then describes the effect of this honey on a cat. He says:

The animal could scarcely be induced to move; and when motion was attempted, first the fore limbs would fail, and then the back limbs would give way. First one portion of the body would sway in one direction, then the other portion in another, reminding one of a highly intoxicated person. Had the entire dose been retained, death undoubtedly would have followed. As it was, the cat had regained her normal condition only at the end of 24 hours.

The physician who attended the persons afflicted with similar honey, writes:

Only two persons partook of the honey: all the rest of the family and the servants ate of each of the other articles served for breakfast, and were not in the least affected. Mr. and Mrs. Chambers took but a small quantity, yet each noticed a peculiar, pungent, burning taste in the comb as soon as it had passed their lips. In 15 or 20 minutes afterward Mrs. Chambers was taken with nausea, abdominal pain, and vomiting, soon followed by loss of consciousness, coldness of extremities, feebly acting heart, and complete collapse. While ministering to her, Mr. Chambers, who had also experienced the initiatory symptoms of pain and nausea, suddenly exclaimed, "I can not see," and soon sank in a state of syncope on the floor. In each case the symptoms were similar—retching, vomiting, purging, acute gastric and abdominal pain, and continued cramps for some hours, with surface coldness, deadly pallor, and the general symptoms of collapse.

No deaths resulted. Many plants are mentioned as being noxious, but they seem to be very rare, and far apart. *Kalmia latifolia* is mentioned as being bad. While this writer says no case of poisoning from heather has been reported from Scotland, where this plant (*Ericaceæ*) is perhaps the chief source of honey, he still advises bee-keepers in New Jersey, where this plant abounds, not to put hives where bees can have access to it.

The reading of Prof. Cook's article, just preceding, makes the following quotation necessary, as it seems to refute, in one particular, what he says:

When the poison is an alkaloid, as gelsemine, the problem is easily solved. The bees simply collected nectar from certain narcotic plants. But some one argues that it is impossible for these little creatures to collect and store a poison and not be killed themselves. There is scarcely a narcotic herb that does not give support to some form of animal life. What is nourishment and life to one is frequently poison and death to another. Many of General Braddock's horses perished from eating leaves of the laurel during the month of June, 1755, a few days before his defeat,

yet pheasants will eat and thrive on the buds and leaves of the *kalmia latifolia* in times of scarcity; but their flesh becomes so permeated with the poisonous principle that persons have frequently been poisoned by eating it. Such a large number of cases of poisoning from this source at one time occurred in Philadelphia that the mayor was compelled to act by prohibiting the use of pheasants for food. Again, who can positively state that the mortality of bees is not increased in poisonous pasturage?

All who desire to read the article in full can doubtless get it by addressing the journal referred to. It is printed in New York.

#### NOTES BY THE WAY.

With the Bee-keepers at Rocky Ford and Denver, Colorado.

BY J. T. CALVERT.

On my way back from California I stopped four or five days in Colorado. I spent a very pleasant day at Rocky Ford with Henry F. Hagen, quite an extensive bee-keeper who has for several years been supplying the bee-keepers of that vicinity with their hives and supplies. Mr. Hagen produces comb honey exclusively, and uses a section  $4\frac{1}{2}$  inches square, 7 to foot wide, on T tins, in the regular Dove-tailed super, made  $\frac{1}{8}$  inch deeper to provide for shrinkage in their very dry climate. He prefers this section for much the same reasons that have been urged in favor of the 4x5x7-to-foot Danz. section—it makes a pound to the box, with a thinner comb and larger comb surface. He has had no trouble in selling all the honey he could produce, and much more that he has bought in that vicinity at good prices. In fact, he was behind on orders when I was there, to the extent of nearly a ton.

Honey in this region is gathered almost exclusively from alfalfa. There was a great deal of clover, or Rocky Mountain bee-plant, in bloom, and bees were gathering some honey from it. This honey is darker in color, and stronger in flavor. The bees seem to prefer the alfalfa; and the great areas of this clover, with the beautiful blue flower, generally furnish abundant pasturage. We visited a number of bee-keepers in and around Rocky Ford, most of whom follow Mr. Hagen's methods. A few bees might be seen at nearly every farmhouse. I was assured that, within a radius of five miles, there were at least 2000 colonies of bees. In many parts of the country we should consider this overcrowding; but most of these bees seemed to be getting plenty of honey. Those surrounded by alfalfa-fields were doing much better than were others in town with less of this source of their best honey near at hand. This strip of land, several miles wide, and lying to the east and west of Rocky Ford, and furnishing pasturage for thousands (and I might almost say ten thousand) colonies of bees, depends upon irrigation almost entirely for vegetation. As the river leaves the higher ground to the west it becomes the feeder of several large irrigating-ditches which follow the high ground, giving just enough fall to carry the water. Side ditches and runs distribute the water all over the ground, converting the almost barren desert into a rich garden.

Rocky Ford is becoming famous for its melons, both cantaloups and watermelons. This year's crop was estimated at about 250 carloads of each. It requires about twelve carloads of crates, besides many thousands of baskets, to put up the crop for shipment.

Quite a start has been made in fruit-growing, and this pursuit gives promise of developing to large proportions, and will become a source of large revenue to the district. I tasted some plums and peaches which were as fine as any I have ever seen. The climate of this section of Colorado is delightful, and much more beneficial to people with pulmonary ailments than the higher altitude further west. On the western horizon, a little to the north, Pike's Peak may be clearly seen, eighty-five miles distant, with its snow-clad summit 14,017 feet above sea-level. Thither I made my way after stopping a few hours in Pueblo, and making a call on A. R. Pierce, who furnishes a good many bee-keepers tributary to Pueblo with their supplies.

I stopped 24 hours in Manitou, and enjoyed to the full this brief stay amid its natural wonders. One who has never seen the mountains can form no idea, from description, of their sublime and stately grandeur. After partaking freely of the water from the soda springs for which Manitou is famous, I proceeded at once to visit the many "points of interest." Beautiful streams of clear water from the mountains, tossing down the canyons over the rocks, make music delightful to the ear, and add to the charm of the wonderful works of God seen on every hand. One is well repaid for a visit to the Cave of the Winds, or the grand caverns. Temple Drive and the Ute Pass are full of interest. The Garden of the Gods, with its cathedral spires of red rock, balanced rock, and other rocky formations, is worthy of a visit.

The most thrilling experience is a trip to the summit of Pike's Peak. This we made on what is called the cog railroad. This road is about 9 miles in length, and in that distance rises to an altitude of over  $1\frac{1}{2}$  miles as it winds up the rocky mountain-side. There are various ways of making the ascent. Some walk up, while others ride the little mountain burros. There is also a carriage-drive of over thirty miles, reaching to the summit. All of these take more time; and as my time was limited I chose the quickest route. Unfortunately it was a cloudy day, and the view from the summit was thereby much obscured. It was a magnificent view, nevertheless. To get a bird's-eye view of the country for hundreds of miles in every direction is an experience rarely enjoyed. The Cripple Creek gold-mines could be distinctly seen to the southwest, only about thirty miles away on an air-line. There is a U. S. observatory on the summit, and the thermometer stood at 38 degrees when we were up there about noon. The train on the cog road makes two regular trips to the summit each day; and the *Pike's Peak News*, containing the names and addresses of all on board, is printed at the half-way house while we are up the peak, and sold to the passengers on the return trip.

My next stop was in Denver, where I spent two days meeting face to face those whom I had long known through correspondence and in a business way. I found that the L. A. Watkins Mdse. Co., who had succeeded Barteldes & Co. in handling our supplies, had done a fairly good business considering the conditions which existed last season. Frank Rauchfuss, secretary of the Denver Bee-keepers' Association, and manager of the bee-supply department in Watkins' warehouses I found to be a very pleasant and engaging young man of considerable experience as a bee-keeper. In company with him I visited Mr. W. L. Porter, who has some 900 colonies of bees in various apiaries near Denver. Mr. Porter produces both comb and extracted honey, the larger part, I believe, being extracted. He has a local market for all he secures, much of it put up in glass for retailing. I was agreeably surprised to find in the number of places where I stopped throughout the West, so good a home market for choice honey at very fair prices.

Mr. Porter has been carefully testing hives of 8 and 10 L. frame capacity, and comparing them. He at one time seemed to be in favor of the 10-frame size; but this year his preference is for the 8-frame. His honey is gathered chiefly from alfalfa, and is beautifully heavy, and light-colored. When one works up a trade in such honey, and is always careful what he puts up, to see that it is only first class, he may be sure of a permanent and growing demand, and at good prices.

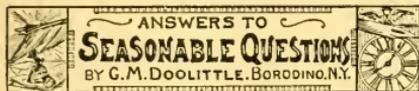

I spent a number of pleasant hours with J. C. Frisbee, who, in company with his father, R. K. Frisbee, is engaged in putting up honey in glass jars and selling to the retail trade both comb and extracted honey. Their honey seems to be lighter in body, and to remain liquid much longer, than most alfalfa honey which I have seen, judging from the samples which I examined.

Many bees in the vicinity of Denver were afflicted last year with a peculiar malady which wasted away some apiaries entire; and some whose bees were not entirely destroyed were so discouraged by the experience that they sold out at a great sacrifice. This disease was mentioned by R. C. Aiken in an article on p. 479. I found, when I reached Omaha, Neb., and stopped there with R. M. Lewis, one of the principal bee-keepers of that city, that the bees there this year seem to be affected in the same way as those were last year around Denver. The disease seemed to affect the bees in much the same way as paralysis, and yet it seemed to be more fatal, strong colonies wasting away in a very short time. It was confined to a limited area about Denver last year, and this year in Omaha the bees affected are mostly within a radius of five miles. It has puzzled the bee-keepers, and is puzzling them to this day to know the cause. There are large lead and silver smelting-works in both territories affected, and some have assigned the cause to the poisonous gases from the smelting-works. But if that were the cause, why should it not operate every year? It is surely something that should be thorough-

ly investigated, for it is a source of very great loss to the bee-keepers subject to its ravages.

Denver is a very fine city, beautifully located in sight of the mountains with their summits of perpetual snow. One peculiarity of Denver which stands out in marked contrast to any other town or city I have visited is the fact that all its buildings, including the dwelling-houses clear out to the suburbs, are either brick or stone. No wooden structures are in sight anywhere. This gives the city a solid, substantial look. Wooden building-material has been expensive because it must all be imported, while brick and stone are plentiful; besides, a city ordinance is no doubt the chief cause of the absence of wooden buildings.

On my trip through Iowa I made E. Kretchmer a short call, and found that he, like the rest of the bee-supply manufacturers, had had a good trade the past season. I also spent a day in Des Moines and another in Chicago; but I shall have to defer till the next issue the account thereof.

#### SUGAR SYRUP FOR BEES — HOW MADE.

*Question.*—Will you please tell us in the next issue of GLEANINGS how to make sugar syrup for winter stores for bees? I think you have given your recipe for syrup for winter feeding in some of the bee-papers before, but I can not turn to it just now. The season did not turn out as well as we were promised at first, and hence many of us will have to feed.

*Answer.*—Years ago we were told of many plans to make a feed of sugar that would answer for winter stores for the bees; but upon using most of the plans I found them to be failures along certain lines, the one most common being that the syrup would crystallize in the feeders and in the cells after being fed. Not being satisfied I went to experimenting in different ways; and while studying over this matter it occurred to me that, years before, during some experiments made to prevent honey from granulating, I had used sugar in one of these experiments, which syrup had accomplished the desired end, that of keeping the honey liquid when cold weather came. I said to myself that, if sugar syrup would keep honey from granulating, why would not honey keep sugar syrup from crystallizing? So the next batch of syrup was made as follows:

Fifteen pounds of water was weighed out and put into a tin vessel of suitable size. This vessel was then put over the fire till the water was brought to a boil, when 30 pounds of granulated sugar was poured in, stirring the same briskly while putting in, so that it would not settle and burn, as such sugar is sometimes liable to do if not stirred. The stirring was kept up till the sugar was partially dissolved, when it was left over the fire till it boiled

again, when it was skimmed if impurities arose. It was then taken from the fire, when 5 pounds of good thick honey was poured in and stirred for a moment or two, so that the whole should be mixed thoroughly. This honey proved to be just what was needed, for syrup thus made remained liquid day after day, when not fed to the bees immediately, although with this formula the syrup was nearly, if not quite, as thick as the best honey. And I found that, after keeping it for several months by way of experiment, it proved as good as ever, not crystallizing or souring at all. Thus I had a feed that was easily made, and that would remain good whether in the hive or out; and after years have passed I use the same whenever the season has been so poor that I am obliged to feed in the fall.

The honey first used was extracted basswood honey; but of late years I have used that which has accumulated from the wax-extractor, no matter how badly mixed or of what color. I find that honey coming from the solar wax-extractor, by way of a little honey being in the bits of comb and wax placed there for melting, is always the nicest kind for any manner of feeding, no matter what the color may be, for the heat of the sun so ripens and thickens it that it is always prime for winter stores. If no honey can otherwise be had, that from partly filled sections will answer.

#### PREVENTING SWARMS IN AN OUT-APIARY.

*Question.*—If you were going to run an out-apiary for comb honey, how would you manage to prevent swarming?

*Answer.*—Well, as I have an out-apiary that is run for comb honey, perhaps I can answer this by telling what I do at that out-apiary each year. If I wish any increase I proceed as follows: Placing a hive all rigged with frames filled with foundation or empty combs, on the stand of one of the populous colonies which I think may be getting ready to swarm, I next set the sections from the old hive on the new, when I proceed to shake all of the bees off their combs and out of the hive, letting them run into the hive I set on their former stand. I now place the combs of brood back in the hive again and carry the whole to the stand of another populous colony, setting this last colony on a new stand from 10 to 100 feet distant. The sections are now put on the hive of brood, into which the bees returning from the field are now pouring. When they find that this is not their old home they are somewhat homesick; and if their old home is nearer than ten feet, many of these bees will find it, and, setting up the joyous hum of "home is found!" will call most of the bees away from the brood, which is not a desirable thing; hence I place the removed hive 25 feet or more away if it is possible to do so. I generally carry along with me some nearly mature queen-cells and give this made colony one of these in a queen-cell protector. This protector keeps the bees from destroying the cell till they realize their queenless condition, which happens a little before the cell hatches, so that, when the queen emerges, she is kindly received, and in due time becomes the head of

the colony. In this way one new colony is made from two old ones; all desire for swarming is broken up, unless the season of surplus honey is long drawn out, while all three are in the best possible condition to store surplus, after a week or so has elapsed. If I wish no increase I usually cage the queen just before the bees think of swarming, leaving her caged for ten days, when the hive is opened, the bees shaken from every frame, so as not to miss any queen-cells, when all such cells are cut off, which makes the colony hopelessly queenless, except for the queen in the cage. If this queen is a good one I use her; if not, I give them a young one brought with me from my queen-rearing yard, or obtained elsewhere. But, no matter what queen is used, I proceed as follows: After removing the stopper from the cage containing the queen I wish the colony to have I insert another, this latter one having been prepared beforehand by boring a  $\frac{3}{8}$  hole through it. Into this hole is stuffed all the candy (such as is used in shipping queens) that it will hold, and the hole should not be less than one inch long. Having the queen and cage thus fixed, the cage is placed in some frame having a little vacant space free from comb, near the bottom; or if none such is found, I make a place large enough, when the hive is closed. To eat through this candy takes about five days, or the colony is without a laying queen for fifteen days, which time I find amply sufficient to stop all desire to swarm. While no eggs are being laid for the fifteen days, still the colony has a queen all the time, and, so far as I can see, work goes on in the sections nearly or quite as well as if the queen were out at liberty.

WHY SO MUCH WHITE CLOVER THIS SEASON?  
PAPER IN FOUNDATION; SOWING  
SWEET CLOVER, AND WHEN.

In *Stray Straws*, page 549, you speak of the wonderful growth of white clover this year, and as to the cause. I think it is accounted for by the root growth during the dry seasons when the clover scarcely appeared above ground, but was gaining in strength under ground from its long rest.

You did well to conclude to retain the paper in the packing of foundation.

If Dr. C. C. Miller will lay the material for sections on the grass under a good large apple-tree he will not need to use any water in the grooves, and the sections will be much nicer in folding.

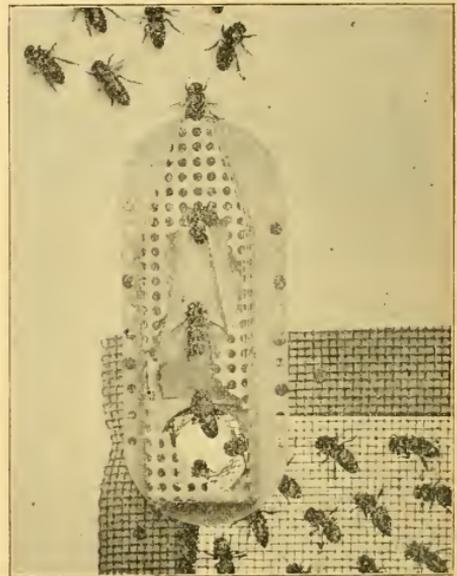

In regard to the sowing of sweet clover, as per inquiry on page 573, you can safely sow in spring as early as the ground will work well, say in March if possible. The ground should be well plowed and harrowed before the seed is sown, and once harrowed after sowing.

Then the ground should be well firmed, as Peter Henderson would say, if living. I find it a good plan to take about four or more horses, and hitch them abreast and drive them back and forth over the ground until it is packed solid. If driven in straight lines the foot-marks of the horses will cause the clover to come up in rows, and will insure a good crop. This way of putting in clover of the kind mentioned has proven the best in the dry lands of Kansas; and, if the ground is dry, I think it will be a great help anywhere.

Cuba, Kan., Aug. 11. W. H. EAGERTY.

THE OPERATION OF THE HONEY-HOUSE PORTER BEE-ESCAPE.

We inclose herewith a proof of that better engraving of the honey-house escape that we

have spoken of several times. The original photo of this is, in our opinion, the most difficult thing ever accomplished in the line of photographing live bees. If you question it, we should like to have you try your hand at improving it.

R. & E. C. PORTER.  
Lewistown, Ill., April 24.

THAT NEW BEE-DISEASE; HOW THE BEES  
"EVAPORATED" IN ANOTHER CASE.

I see that you would like to hear from parties in regard to the new bee-disease. Bees were in fine condition here the first of July. We never had a better prospect. Hives were boiling over with bees. Some had commenced in the supers. I examined them again about the 10th or 12th of July. Now, you no doubt have examined a colony as soon as they have cast a rousing swarm. That is just as near as I can tell you how things looked the 10th and

12th of July last. Very few dead bees were in front of the hives. The weather was very warm about that time, or some or most of the brood might have become chilled, for there were not enough bees left to cover the combs. Queens, larvae, and brood seemed to be perfectly healthy.

Bees in a circle of two miles seem to be affected, some more and some less.

At present writing bees are still reduced in numbers. Out of 50 stands there is not one pound of surplus honey in the yard.

On page 555 Mr. Whitcomb tries to make us believe that too much cold water is the cause of all our troubles. Now, did you ever hear of such a thing as pure water hurting bees in the month of July? He says, further on, that the water from the mountains in Colorado is cold, and that the bees drank, and were chilled. Now, it is facts that we want—no guesswork about it.

There is something wrong with the bees here now; that is one fact. I am not going to tell you what is the matter. I am like Dr. Miller—I "don't know." JAS. RAE.

Petersburg, Neb., Aug. 12.

[I talked with Mr. Whitcomb in regard to this very matter, at Buffalo. He stated that the water coming from the mountains, as it does, is very cold, and his experience has shown that ice-cold water is very injurious to bees. I do not know that I am competent to speak for him on this question, and therefore will ask him to write further as he may see fit.—ED.]

#### OBJECTIONS TO SOLDERING FRUIT-CANS FOR HONEY PURPOSES.

I have been reading Mr. Aikin's articles and your comments on pages 407-409, and 443, '4, in regard to honey-packages. It seems to me the fruit-can idea will be the cheapest; but the soldering of the top strikes me as inconvenient, both for the producer and the consumer. Fruit is generally used up at once after being opened; but honey will in most cases last for some time, and consequently the can will have to be tied up in some way to keep out impurities. This is impractical.

The grocers here sell an article called "butter oil," put up in quart fruit-cans. These cans have a small tube soldered on the top, through which this oil can be emptied. The tube on top is about  $\frac{1}{2}$  inch high and  $1\frac{1}{4}$  to  $1\frac{1}{2}$  inches in diameter. It has a cork about  $\frac{3}{8}$  inch thick, and above the cork the tube is filled with what seems to me to be plaster Paris. From 12 to 24 cans are in a box that is just high enough to hold can and tube on top. If the hole in the top of the can is punched outward,  and the tube soldered around this  beard, then the can may be perfectly drained of its contents. Besides the tube on top of the can there is a wire ring, by which the can may be carried. It seems to me a can of this description ought not to be much higher in price than the common fruit-can, and may be of some use till something better makes its appearance. At any rate, I believe it will not hurt, and may

be of some benefit if you consider this kind of can before you go into manufacturing any kind.

H. RAISCH.

Vineland, N. J., June 19.

[The difficulty of soldering up cans is not as great as you think, friend R. The very cheap soldering-kits now on the market, with directions accompanying them, make the operation of soldering the top on to the can a comparatively simple one.

The idea of using a tin neck on a can, with a cork, is very good; but the objection to any such thing as that is that it sticks up above the top of the can, and it is not practicable to tier one layer of such cans on top of another in one box. Cans that are soldered, however, are flat on top and bottom, and can be very easily packed in boxes, with little or no danger of leakage.—ED.]

#### POOR SEASON.

Noting the large crops of honey all over the land, I can say that we are not in it. Out of 35 colonies, spring count, I had 8 new swarms, and 5 starved to death at this date. I took from one to ten sections from eleven hives, and that is all dark and bitter. I have not opened the 1000 sections sent me last spring. Honey-flow ends here June 1st. No sale for the little I have on hand. As I must feed, the little will come in handy. J. H. ALLEN.

Box Elder, Va., Aug. 5.

#### BEEES CLUSTERING OUT; TILTING UP THE HIVE-COVER.

I see from a note in GLEANINGS that you are somewhat troubled about your working bees clustering on the outside of the hives in very warm or hot weather. Now, for your benefit, and it may be for other bee-keepers', I will state that I solved this question several years ago here in the South, and I see no reason why my remedy will not work equally well in the North. You could visit my apiary the hottest days that we ever have here (and many of my 200 colonies stand in the sun), and you could at any time find but few bees outside.

I work for extracted honey, and use the ten-frame standard Dovetailed hive, two stories high. If at any time bees begin to cluster outside I know the cause is heat and want of ventilation. I raise the rear end of the hive-cover one inch or less, according to the intensity of the heat, with a small block or a wedge-shaped stick. This will start a current of air through the whole hive, and the bees will soon proceed to business.

J. W. WINDER.

New Orleans, La., Aug. 11.

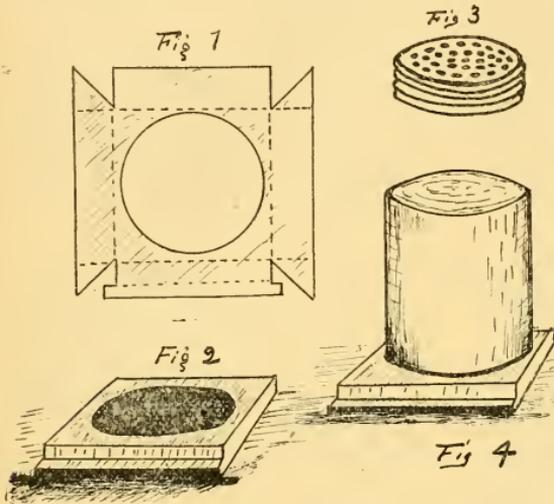

[The tilting-up of the hive-cover is quite an old idea. Sometimes it works and sometimes it does not—at least that has been my experience. But, friend Winder, don't you think that the tilting-up of the cover, while it may cause the bees to quit clustering out, may be letting too much heat escape? The super should be very warm—the warmest part of the hive. The method I advocated for making

the bees go into the hive does not call for cooling air-currents through the supers.—ED.]

#### HOW TO MAKE YOUR OWN BEE-FEEDER.

I have kept bees for over fifteen years, and have always made my own bee-feeders—first wooden boxes and lately a kind of pepper-box

feed, or it can be placed on the frames inside of the hive. As there is no bottom to the base I can fill the can with syrup, screw the cap on, then invert it and place it where wanted, giving the bees access to the perforations, and it will work on the atmospheric principle, so that the feed will run out no faster than the bees can take it. It will hold one quart and half a

pint. I have in use larger ones that hold a gallon, made on the same principle, or nearly the same, out of the gallon cans that are advertised on page 24 in your catalog. I make the can tight so no air can get in; and, after making an opening, and soldering a screw top (the screw top can be placed on the end or side of the can over the opening), I solder a strip of tin one inch wide around on the under side of the can, so as to raise it up and have it answer the same purpose that the base does to the other. I make the projection by soldering on a narrow strip of tin against an opening made for the bees to get under on the under side of the tin rim.

J. L. HYDE.

Pomfret Landing, Ct., May 14.

feeder that does not cost me much, and will answer the purpose better than any that I have before seen or seen described. No doubt many a bee-keeper who has old fruit-cans or the like lying around would like to know of some good use he could put them to. To such I will describe my method of converting them into bee-feeders.

First take a quart or 3-lb. can, such as tomatoes or canned squash is put up in, and cut out one end, if it is not already out, and solder on to this end a screw top pricked full of holes like Fig. 3. You will find the screw top that you will want, mentioned in Root's bee-keepers' supplies, page 24. Get the 4-inch cap.

Fig. 4 is a feeder completed. After the screw top is soldered on to the end of the can, Fig. 4, it is inverted and pushed through the hole of a box or base, Fig. 2 (which is made for the purpose), far enough so the screw top will be on the under side of the box, the remainder of the can being above, as at Fig. 4. This box is about one inch high, without bottom, and is made in this way:

Take a sheet of tin a little over 6 inches square, and cut into it about one inch, and clip part of the corners out as shown in Fig. 1, and then the sides are bent over where the dotted lines appear, which forms the box. You will see some dotted lines on the lower side, which should be bent out where these dots are, and the ends of this part bent down so as to form a lip that will slide into the entrance of the hive. This projection is shown at Figs. 2 and 4. I use these, either as entrance feeders by putting the projection into the entrance so no robber-bees can molest the

#### LANGSTROTH MONUMENT; ANTS A NUISANCE IN KANSAS.

Inclosed please find amount for the Langstroth monument fund. I should like to say to you that the monument should be made of stones that would be low and heavy rather than slim and tall, for the reason that they should last for all time, as it were. I should like it if the upper stone of the monument could be made in the shape of a bee-hive, say like the chaff hive put up by the A. I. Root Co.

In looking over the A B C of Bee Culture I find in regard to ants that they will do no damage; and in proof of the assertion we read they did not trouble the hives containing old honey. Now, old honey is not the nectar from the flowers that new and fresh honey is, as I understand it. The ants out here get up a raid on a colony, and, like Grant in the Wilderness, they get all the help they can. The raid is made in the night time, and the morning sees all the bushwhackers at home again. I tell you it will not always do to let them have the field to themselves. I use a crusher made like a man's slipper, but made of wood, with the bottom shaped like an old log canoe, or dugout. Attached to the wooden foot is a long handle. I run the crusher sidewise over the ground, and crush the ants quite fast. I find that after a rain is the best time to crush the ants. I do not get rid of them all, but I keep the numbers down so that the bees can master them. The little black ants are the worst.

## COMB-BUILDING AND WING SOUND.

You will find in the A B C of Bee Culture, page 177, fortieth line, "As nearly as I can discover, they moisten the thin ribbons of wax with some sort of fluid," etc. Don't they use the acid from the sac wherein they carry the poison, to help them work the wax? and is not that the cause of their jumping about so, and letting the comb stand in a partly finished state until the poison becomes diffused in the atmosphere, and they can go on with the work again. On page 230, 16th line, you say again that "the sound is produced by the wings." I think it is produced by the air-pipes—the ones used to inflate the air-bags, and which all bees use to fill themselves with before taking flight. These things are of little consequence; and if I were writing for publication I would not mention them; but I wish you to give them your attention and make of them what you can.

WM. H. EAGERTY.

Cuba, Kan., Aug. 20.

[You are perhaps right in both of your suggestions. I would refer them to Prof. Bruner, of the Nebraska State University, at Lincoln, Neb.—ED.]

## WINTERING IN THE DANZENBAKER HIVE.

The question was asked at the bee-keepers' convention at Buffalo, if my hive would winter bees as safely as the Langstroth, with deeper brood-frames, which measures 10 inches from top of hive bottom to cover. My hive has a deeper space,  $\frac{7}{8}$  inch, under the frames, with  $\frac{1}{2}$ -inch top-bars in brood-frames, making  $8\frac{1}{2}$  in. net from hive-bottom to hive-covers, only  $1\frac{1}{2}$  in. less than the L. hive, and  $6\frac{3}{4}$  in. depth of comb surface, or only  $1\frac{1}{4}$  in. less than the 8-frame Dove. hive, which has 1088 sq. in. of comb surface, while the ten Danzenbaker frames have 1080 inches of comb surface; and being nearer square, and more compact, with thick closed-end frames and closed air-spaces forming  $2\frac{1}{4}$  inches protection at the ends of combs, must have the advantage under like conditions as a safe wintering hive.

In GLEANINGS, March 1, 1890, p. 168, appears a report of the Wisconsin convention, by A. J. Root. In this report, as an allusion to the B. Taylor shallow hive and its safe wintering, Mr. Root says of it:

Mr. B. Taylor, of Forestville, Minn., contributed a good deal to the meeting. He brought a model of his bee-hive, which he has had in use 25 years or more. He calls it the "Handy" hive. Fully 25 years ago he formed the idea of having the surplus apartment exactly like the brood-apartment—that is, so far as size and shape were concerned. Of course, the brood-combs would have to be made shallow in order that they might answer tolerably for holding the frames small enough for surplus. Accordingly he makes all stories of his hive so as to hold a frame only  $4\frac{1}{2}$  inches deep. This depth was decided upon from the fact that fence-boards 6 inches wide were always to be had, of pretty fair lumber, and at a comparatively low price. The hive is made with beveled joints, to keep out wind and rain, and to keep them in place, very much as I designed the Simplicity hive originally; but his hives are (as mentioned) only about half the depth of the regular Simplicities. As he makes the hive square instead of oblong, the shallow frames contain from three to four pounds of comb honey. He has a special mode of manipulating them so as to get large yields of surplus comb honey, and, also, so as to manage artificial swarming in a very expeditious and certain manner. He winters in the cellar, and prefers only *one* story for wintering, even with combs only  $4\frac{1}{2}$  inches deep.

I think it may be said, that, if frames  $4\frac{1}{2}$  in. deep winter bees safely, one  $7\frac{1}{2}$  will; and when the inside dimensions differ only  $1\frac{1}{2}$  in., there can be no difference under like conditions; but as my 10-frame hive is more compact, and nearer square, than the 8-frame L. hives, with both ends better protected by the space of  $2\frac{1}{2}$  in. from outside to edges of the combs, it must be safer as a winter hive, as many reports have shown. See my book, "Facts about Bees," p. 61.

F. DANZENBAKER.

Bees have done well this season. I have extracted as much as 200 lbs. per hive.

Lisbon, Tex., Aug. 14. J. D. GIVENS.

I have 120 lbs. of comb honey from one hive that did not swarm. How is that for a poor locality?

R. STEHLE.

Marietta, O., Aug. 11.

I have some hives from which I took off 98 lbs. of honey, June 28. I think they will have 70 lbs. more.

O. F. WITTE.

North Amherst, O., July 5.

This closes one of the best seasons for honey that this section has ever had. Almost every bee-keeper's bees have done well. My stock did excellently.

DR. S. H. HURST.

Laconia, Ind., Aug. 12.

My bees did well this year. I have taken up to date 4500 lbs. from 100 hives; shall get 6000 or 7000 lbs. this season. I am going to sow one bushel of horsemint seed. I had some sown this year. I think it paid.

Elmton, Tex., July 30.

J. F. TEEL.

## LARGEST CROP EVER HAD.

I have the largest crop of honey I ever had—white clover. I had one colony that made 90 lbs. in sections, as white as snow. If it ever clears off I shall have another crop, from goldenrod. I have about 100 basswood-trees but they didn't have any blossoms on this year.

MILLARD MAPES.

Monroe, N. V., Aug. 5.

ONE COLONY IN THE SPRING, INCREASED TO 8; \$19.00 WORTH OF HONEY; AND "MORE TO FOLLOW."

I have had success beyond expectation. I started last year with one stand of bees; have increased from same, and have to-day 8 stands; received a big spring crop, and am assured of a good fall crop, as my supers are about full, and some are being capped. I sold honey from my spring crop, amounting to \$19.00; and still had plenty for my family. Now I have the fall crop. I never had any experience before in bee-keeping.

M. M. ANDERSON.

St. Louis, Mo., Sept. 7.

STIRRING honey very much unnecessarily is apt to make honey candy prematurely, said J. F. McIntyre, of Fillmore, Cal., on the floor of the Buffalo convention.

E. A. WANDER, of Hartford, Conn., at Buffalo, gave the result of an experiment of his with 8, 10, and 13 frame hives. As I remember it, his 8-frame colonies gave him an average surplus of 37 lbs. of honey; his 10-frame colonies 56 lbs., and his 13-frame colonies 113 lbs. Perhaps in another locality the result might be very different.

MR. E. T. ABBOTT, of St. Joseph, Mo., at the Buffalo meeting, said that, in his opinion, it was a wrong notion that the small bee-keeper and the farmer and the amateur bee-keeper were the enemies of the specialist honey-producer. "Why," said he, "they are our best friends." The product that they put on the market could not compare with what he could produce and sell, and he thought they actually helped him to make sales at a much higher price for his honey.

#### A NEW IDEA.

IN a paper that R. C. Aikin sent to the Buffalo convention, he put forth the rather startling idea that, in his opinion, it might be more profitable to take extracting-comb, cut out the honey and all, "squash" the honey out of the combs by passing them between rollers, and then melting the wax. His point was that extracted honey was going down in price, and wax going up; that wax and honey, sold separately, would bring more money than if the combs were extracted in the ordinary way, and preserved. This met a protest on every side, and it was mainly to the effect that wax in combs is much more valuable to the bee-keeper than the same wax in cakes.

#### A SAD AFFLICTION AT THE HOME OF W. Z. HUTCHINSON.

WHEN we saw our friend W. Z. H. at the Buffalo convention, looking brighter and happier than usual, little did any of us imagine the sad blow that he was so soon to be called upon to endure. We have been aware for some time past that both his good wife and daughter Ivy have been suffering from a peculiar mental affliction; and we knew, too, they had been sent to a sort of asylum for treatment. On the Saturday afternoon after the convention, Aug. 28, the mother, it seems, had a sudden stroke of her old trouble; and before friends could interfere she had chloroformed little Fern, only five years old, and almost succeeded in taking the life of the afflicted older daughter. Of course, she is now in charge again of the asylum, where she

is supposed to be in safe keeping. This is one of those very sad affairs for which we can hardly call anybody to blame. Mrs. Hutchinson was supposed to be much better, and had been at home some time, if I am correctly informed. May God help our afflicted brother through this his great and terrible ordeal.—A. I. R.]

#### DEATH OF DR. JESSE OREN.

ABOUT the time I first turned my attention to apiculture (August, 1865), Dr. Jesse Oren also became interested in introducing the Italian bees in his locality, Laporte City, Ia. He soon became, with myself, a frequent contributor to the *American Bee Journal*, then newly started, and for many years his name was almost a household word among bee-keepers. Some of you will remember that, during my visit to Florida, I was most pleasantly entertained at his residence in Daytona. When I offered some apology for going to a private home when I was obliged to be particular, and, as it might seem to some, fastidious, about my diet, he and the family hastened to inform me that it would make them no extra trouble at all, for the doctor had been obliged for years to abstain from every thing containing the least particle of starch or sugar. His trouble was diabetes. When I asked him in regard to the matter, he told me he should live but a short time unless he were thus particular in regard to his diet. Of course, they gave him all the variety they could without overstepping the line that through years of suffering had been mapped out by himself and by the advice of other physicians. He was a devoted Christian, and was ready to go when the Father called, for he had been many long years living a life of "thy will, not mine, be done." His death occurred Aug. 26, in the 73d year of his age, in Laporte City, Ia. From a local paper we quote:

Examination shows death to have been caused by suppuration of the gall-bladder, due to the presence of a large gall-stone, and an abscess of the upper portion of the left lung, the result of pneumonia.

Dr. Oren was a man of considerable wealth, and I think he told me in conversation that the greater part of it had come either directly or indirectly from bee culture. He produced large crops of honey year after year for so long a period without failure that he has been quoted largely as an example of what persistent care and attention may do in our industry. For many years past, on account of his health, he has been passing his winters in his beautiful home at Daytona, Fla.—A. I. R.

#### THE EFFECT OF PREMATURE PREDICTIONS OF THE HONEY-FLOW.

MR. P. H. ELWOOD, at the Buffalo convention, expressed regret that the editors of the bee-journals had predicted a remarkable honey year when subsequent reports seemed to show that the season was not as good as had been expected. The effect of this advance talk he thought had been to lower unnecessarily the price of honey.

There is truth in what he said, and I am willing, so far as GLEANINGS is concerned, to

plead guilty—at least to some extent. From Mr. Elwood's standpoint, or, in fact, from the standpoint of any bee-keeper in York State, the season had not been as good as the last; but in other States I think it has been very much better, if we except also the basswood-growing regions of Wisconsin, Iowa, and Minnesota. All through York State I found that clover had done very much better than it did last year; but the entire failure of basswood very materially dropped the general average. It is easy to see that those States that have generally secured good crops from basswood, owing to the absolute failure from that source, have not had, comparatively speaking, as good a crop as last year. But the great majority of locations throughout our country have given far better averages, as basswood does not grow in those places.

This suggests a question: Suppose there could be no question about it of honey-flow being much better than for years past—would it be wise to publish the fact? or would it be better to let the situation be known? I must confess that, so far as we are concerned, our predictions for the future will be conservative rather than otherwise.

#### SHIPPING COMB HONEY.

A GOOD deal of discussion took place at the Buffalo meeting regarding the best methods for shipping comb honey by freight. Several took the ground that it was bad policy to put cases of comb honey in a large protecting-crate; that the honey was more liable to be broken in such crates than when piled loosely in a car on straw. Others insisted just as strenuously that they never had success in shipping honey till they used these protecting-crates. Among those who advocated putting the cases in a car without the crate were Capt. J. E. Hetherington, Dr. C. C. Miller, and quite a number of others. These latter, *i. e.*, those who advocated the non-use of the crates, very often ship in *large* lots and in carloads; when the cases are piled up solidly in a car (combs parallel to the rails) there is not very much liability of the honey being broken. On the other hand, when honey is shipped in *small* lots, say in five or ten cases, it seems to go better in a crate, especially if it is transferred. But Mr. S. A. Niver, of Groton, N. Y., made the point that those heavy crates holding, say, ten or twelve cases, are pretty sure to be handled in York State on two-wheeled trucks. The crates were put on them the long way; and as they are trundled from one car to another the combs are jolted when held on at an angle of 45 degrees, and the wrong way at that, and this causes the breaking out when they used crates. It was hard for me to reconcile that statement in view of the fact that we had always had better success by using the crates than when we did not use them. When I went through York State I noticed that they used two-wheeled trucks where we in the central and western portion of the country use four-wheeled ones. On the latter, crates holding ten or twelve cases would be handled just as they should be—in a horizontal position.

On two-wheeled trucks, these crates would be trundled and bumped over the plank platforms at an angle of 45 degrees, as explained.

#### THE BIG BUFFALO CONVENTION.

THE Buffalo convention, while perhaps not the largest in point of numbers (and I do not know but it might have been the largest also), was one of the best conventions I ever attended. It certainly was a most representative meeting. There were bee-keepers present from California and the West, from Cuba, from all over New England, from different parts of the South, from every portion of York State, and from all over Canada. There was that extensive bee-keeper from California, Mr. J. F. McIntyre, who has 600 colonies all in one apiary; and there was the editor of the *California Bee-keeper*; that distinguished bee-keeper, O. O. Poppleton, from Florida; E. Whitcomb, from Nebraska; Fred L. Craycraft, from Cuba. There was also present from New York, Mr. W. L. Coggshall, who runs 13 out-apiaries aggregating something like 1000 colonies; P. H. Elwood, having a similar number; Capt. J. E. Hetherington; and—well, I don't know how many more. Besides these bee-keepers with their great ranches, as we might say, of bees, there were a good many more who owned colonies aggregating anywhere from 300 to 500 in number. Then there were the professional men, and the bee-keepers having anywhere from 10 to 100 colonies.

The convention hall was pretty well filled most of the time; and, barring a little passage at arms at one of the sessions, every thing passed off very pleasantly.

One of the special features of this convention were some grand talks from Capt. J. E. Hetherington, said to be the most extensive bee-keeper in the world; J. F. McIntyre, of California; G. M. Doolittle, almost the uncrowned king of the convention;\* Fred L. Craycraft, a bee-keeper who has achieved no small distinction in Cuba. And then there was plenty of good-natured sparring between Drs. Mason and Miller; Messrs. Abbott, of Missouri, and Doolittle, of New York; Hon. E. Whitcomb, of Nebraska, and others whose names do not come to mind just now. Wit and humor, intermingled with song, spiced the whole convention.

No small praise is due to Mr. O. L. Hershiser, of Buffalo, for the beautiful room he secured for us in one of those sky-scraping buildings, top floor, and the excellent entertainment, in view of the great crowds in the city on account of the G. A. R. encampment.

Unfortunately, the convention had no reporter. The one who had been secured disappointed us at the last; and supposing the report was being taken I took no notes; but I am just conceited enough to believe I brought home some ideas, and I hope to sprinkle them into our columns in the forthcoming issues, as time and opportunity may suggest.

\* Doolittle "brought down the house" a number of times by his happy speeches; and later on a strong effort was made to make him president, but he declined with thanks.

#### APIS DORSATA AT THE BUFFALO CONVENTION.

It will be remembered that the Ontario Co. Bee-keepers' Association, made up of bee-keepers of Ontario Co., N. Y., passed a resolution recommending the general government to secure the giant bees. This resolution, after being published, received some unfavorable comment, both in the *American Bee Journal* and in these columns. At the Lincoln convention a counter-resolution was passed, to the effect that the members of the N. A. B. K. A. did not approve of the idea of asking the government to send an expedition for the big bee of India. Shortly after I myself said a good deal against what I termed the "scheme," honestly believing that it would be better to use the money that the government might see fit to give in the interest of bee-keeping for experimental work rather than to pursue after a will-o'-the-wisp—a bee about which we know very little.

On the second day of the Buffalo convention I could easily see that there was going to be a fight over the matter. The Ontario bee-keepers present at the Buffalo meeting, and a good many others of the York State bee-men, were anxious to secure the passage of a resolution from the United States Bee-keepers' Union favoring an attempt on the part of the government to bring *Apis dorsata* to our shores.

I had had some previous correspondence with some of the York State bee-keepers, prominent among whom was W. F. Marks, of Chapinville, N. Y. In one of his letters he said he would be glad to enlighten me in regard to the "dorsata scheme," as I had termed it; and that he hoped he might have the pleasure of talking with me on the matter at the Buffalo convention.

The result of the conversation, both with him and with others, showed that the government was willing to make some effort to get *Apis dorsata* to our country, but that it was *not willing* to give us money for experimental or any other purpose. Messrs. Marks, Ritchie, and others, in our private conference, could see no reason *why* we should oppose the idea when the government had plainly indicated its willingness to secure for us *Apis dorsata*, and when it had so positively declined to do anything else. Why not ask the government to do what it felt inclined to do? The upshot of the whole matter was, that a compromise resolution was passed to the effect that the U. S. B. K. U. assembled at Buffalo favored *any* attempt to bring the big bees here.

Just what course the government will take remains to be seen. In the meantime The A. I. Root Co. will go on with its plan to get the dorsata. If our scheme fails, then we may be very glad to get government assistance; and it is very possible that our man and the government appointee may together be able to accomplish what either one alone could not. Possibly the government could do no better than to select our man; if so, we shall gladly give him up.

In any case, it is not proposed to bring dorsata into a northern climate, but to take them to some point in the South, say Florida. Mr. O. O. Poppleton has signified his willingness,

not only to take care of the bees, but to give them every attention.

#### WHAT I SAW IN YORK STATE; THOSE IMMENSE FIELDS OF BUCKWHEAT.

JUST before this issue goes to press I managed to get home from my trip among the bee-keepers of the East, and just in time to get in a few editorials. I have not space in this issue to tell a tithe of the ideas that I gathered in York State and in Rhode Island, for *ideas* were just what I was after.

For the present I can only say this: That I visited some of the largest bee-keepers in the world, and witnessed their methods of management. Several told me I must see W. L. Coggsall and his lightning operators. Last year he took 78,000 pounds of honey, and this year 50,000. To see those men work, yanking the combs out of the hive, and again yanking the honey out of the combs, was a revelation to me. I'll tell you about it later.

Yes, I have been in locations where from one hilltop could be seen as many as 5000 acres of buckwheat-fields. I have been in counties where there were all the way from 2000 to 3000 colonies. I was in one location (Boomhower's) where bees had access, within a range of three miles, to 5000 acres of buckwheat-fields.

I have known before that New York was a wonderful honey State; but I believe I have had my eyes opened wider than ever before. Why, just think of it! single county conventions in York State being able to muster up 125 bee-keepers! I managed to take them all home in my Kodak, and I'll introduce them later. With the possible exception of California, York State has more bee-keepers and more colonies to the square mile (I was about to say to the square inch) than any other place on the globe; and I am not sure that even California should be excepted.

Now, lest any of you think it would be a good place to migrate to, I want to tell you now to stay where you are. Generally speaking, the whole of York State is overstocked with bees; and any "tenderfoot" who should go into that State thinking he might get a generous slice of some desirable territory not now occupied would be very much mistaken. Why, it seemed to me as if every farmer kept bees, and quite extensive apiaries too.

In order to cover as much territory as possible I used the bicycle, and both steam and electric cars; and even then I had to skip by many a bee-keeper I had hoped to visit. For instance, I had to pass by Mr. Egbert Alexander, of Delanson, N. Y., notwithstanding the fact that I actually passed through his place on the train; but for want of time I just *had* to go on. Well, I was told last year that this man, with his 900 colonies, secured 400 barrels of extracted honey; but these barrels held only about 160 pounds each, I believe. But figure it up for yourself and even then you will find it gives an enormous crop in the aggregate—32 tons. And let me whisper in your ear that, so far as I could learn, the region round about Delanson is very much overstocked; and in saying this I am telling

the exact truth. I should be doing a very great injustice to York State bee-keepers were I to paint the field in such glowing colors that it would produce another Klondike or Oklahoma rush of bee-keepers.

Well, I have secured photographs illustrating apiaries and various new-fangled ideas; and in future issues of GLEANINGS I propose to give in detail something of what I have outlined above.

#### F. DANZENBAKER.

We herewith present a half-tone portrait of Mr. F. Danzenbaker, of Washington, D. C., taken on his 60th birthday. Having never used tobacco in any form, nor suffered a day's illness since his eighth year, he is to-day as active as most men of forty. He inherits

from his father and grandfather, who owned 300 colonies of bees in West Jersey, over 60 years ago, an all-absorbing interest in bees and apicultural pursuits. He says every day in the apiary is for him pleasant recreation, having combined bee-keeping and farming until, in his 50th year, he is satisfied to be known as a farmer bee-keeper.

Having spent many years experimenting to ascertain the best hives and methods for the production of comb honey he has brought out and patented some valuable improvements in hives and appliances. After using the Dove-tailed (or lock-cornered) hive eight years himself, he brought a finished model to us and gave us the first order for Dovetailed hives made in our factory. Since then he has brought to our attention the D. case, named by us after him.

The little book, entitled "Facts about Bees," contains much very valuable information in regard to a variety of operations in caring for bees, invaluable to a beginner, and well worthy a careful reading by the veteran

bee-keeper, even if he does not agree with Mr. D. in regard to the best system for producing comb honey. Indeed, it contains as much and as valuable matter as some books on bees we have seen published and sold for 25 and 50 cts.; yet this will be sent you for simply a 2-ct. stamp to pay postage.

Mr. Danzenbaker, who has been spending a few days in Medina since the Buffalo convention, would like very much to hear from all those who have tried his hive the past season. Write him at Washington, D. C., offering suggestions or criticisms as you may have any to offer, telling him how you have succeeded with the hives.

#### GRADING HONEY.

It is really amusing to see the way different people interpret the same grading-rules. In order to secure uniformity of grade so far as possible, we have printed on a slip a copy of the grading-rules suggested on p. 566, Aug. 1st GLEANINGS, together with instructions for packing honey for shipment, one of which we send to each party to whom we make an offer for comb honey. The sample shipments which have come in, each graded (or represented to be graded) by those rules, are a study. The A No. 1 grade from one man will show up better than the fancy from another, and yet I have no doubt that both endeavored to grade to the rules to the best of their ability. It seems to be next to impossible to make a set of grading-rules that shall be sufficiently simple, and at the same time explicit enough to be so correctly understood that a mixed lot of honey would be graded practically the same by every bee-keeper who should undertake it. We feel as if we were no better off than we were without any rules at all, except, perhaps, that the honey is subdivided into classes, where before, many times, we received it all mixed together.

There is a great deal for bee-keepers to learn along the line of putting up their honey in the best possible shape for market. Those who are the most careful about grading are, as a rule, the most careful in their methods of producing honey; what they secure is all of a better average grade than that of their neighbor who is more careless and slipshod in his management. We have decided that, in order to know what grade we are buying, we must see the honey, or a sample crate of it, before we can be safe in filling orders by making direct shipments from the producer to the customer. There is just as much difference between customers as between producers in the matter of grading. As evidence, here is a case. A Michigan bee-keeper from whom we have bought honey several years sent a crate of honey to a customer in Illinois. On receiving it, he wrote as follows:

The honey you shipped came here in splendid condition; and to say I was pleased with it would be putting it mildly. In fact, I never saw prettier honey. When I need some more I'll know where to send for it.

FRED HASSMAN.

East Alton, Ill., Aug. 18.

The same producer sent another shipment to another customer, and he was very much dissatisfied.

J. T. C.

#### DREER'S GARDENING UNDER GLASS.

Ever since I have been engaged in gardening—I might almost say ever since I have been engaged in business—I have had at different times a longing to see a whole acre—a whole square acre, if you choose—entirely covered with glass, so one could go about and feel that he had elbow room and still be protected from wintry blasts. This longing was for the first time gratified when I caught a view of Dreer's immense establishment.

The group of buildings form a square, or pretty nearly so. The shape of the roof is shown in the cut. Every thing is glass, up above the frost-proof wall, which is perhaps 3 feet high. The ventilators are along the ridge.

Cut No. 2 gives you a view of the interior. The gutters are supported by a U-shaped iron frame that looks like a doorway. See cut.

You will notice from the engraving that these U-shaped doorways are arranged so as to assist in supporting the beds. Said beds are all made of iron, and supported by iron posts. The corners of the beds are rounded, as you notice, for strength, beauty, and to avoid bumping against the sharp angle. The bottom of the beds is slate. In fact, there is nothing about this building to catch fire and burn up, and no insurance is carried on the plant. The framework is of metal pipes, as you will notice. These pipes are filled with water, and a hose can be attached at any convenient point, thus giving water in abundance without any special piping for it. The heating-apparatus is shown beneath the beds, and the capacity is sufficient to protect perfectly the expensive contents of one of these greenhouses. I said to our guide:

"My good friend, can you tell me in round numbers about what it costs to inclose a square acre as we see it done here?"

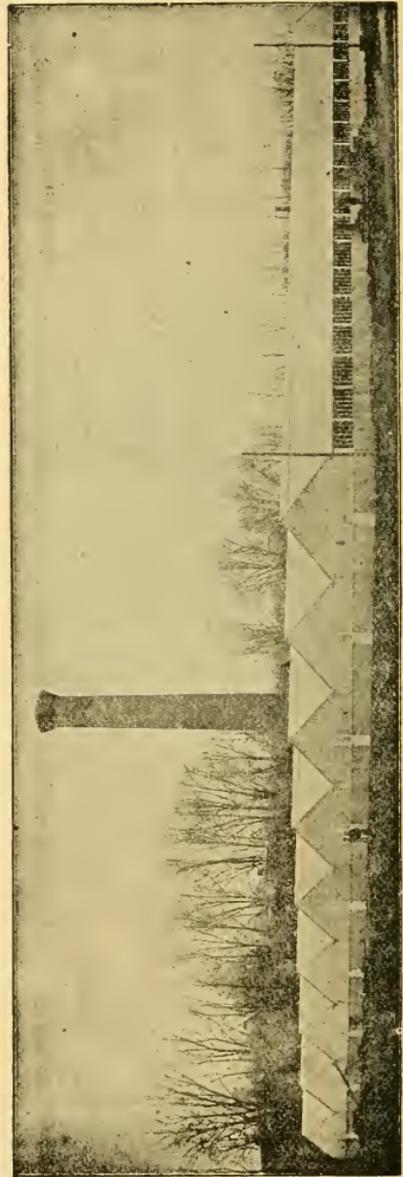

"Well, we have five houses just like this, each one inclosing an acre; and I believe they estimate the expense of each one at just about \$25,000."

"Well, that is about what I expected it would be; and, if I am not mistaken, the beautiful plants that have entirely filled and occupied every foot beneath this glass are worth almost as much more."

"Just about twice as much, Mr. Root. These rare and costly palms and other high-priced plants are worth from two to five dollars each."

Dear friends, it is impossible for me to undertake to describe the beauty of this exotic garden under glass. The mechanical arrangements and construction of the building are perfect, and the plants were each and every one models of thrift and beauty. I did not before realize that there was such a structure or such an array of beautiful plants anywhere on the face of the earth. The sight of it gave

me another of those thrills I have tried to describe. And this view impressed me the more because it indicated at a glance that man had actually triumphed over the constant effort of the elements to tear down and de-

stroy. No wonder our good friend Dreer was able to write that little book that has proved so taking during the past year—"Vegetables Under Glass." Now, it is one thing to build such a structure, and it is another thing to get

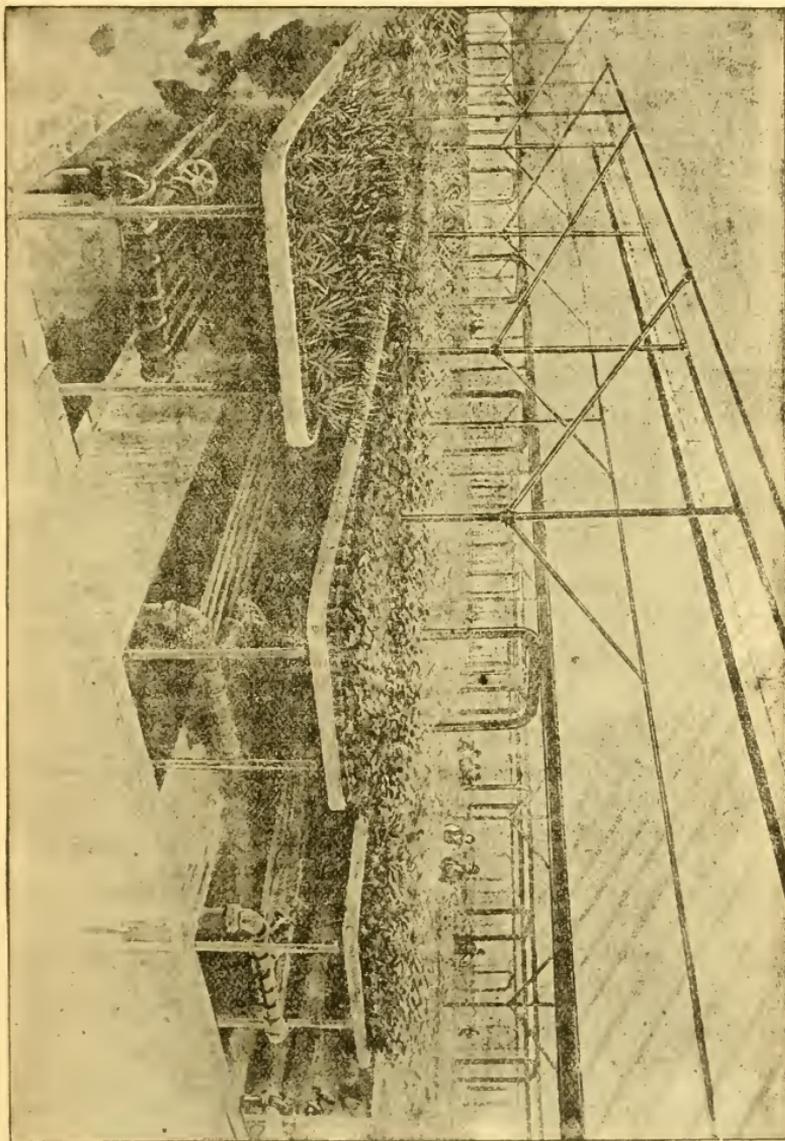

a man who will keep it running so as to pay expenses — high-pressure gardening indeed — and a high-pressure *man* or men to hold the whole institution *up* to the high-pressure point.

Now I want to give you a bird's-eye view of the whole group of buildings, five in number, as shown on next page.

The plant has been gradually built up, as we might expect; therefore there are several minor greenhouses that were built and in use before the other great structures covering an acre each.

You will notice at the right-hand front corner there is a group of cold-frames with sash

INTERIOR VIEW OF THE GREENHOUSE COVERING A SOLID SQUARE ACRE.

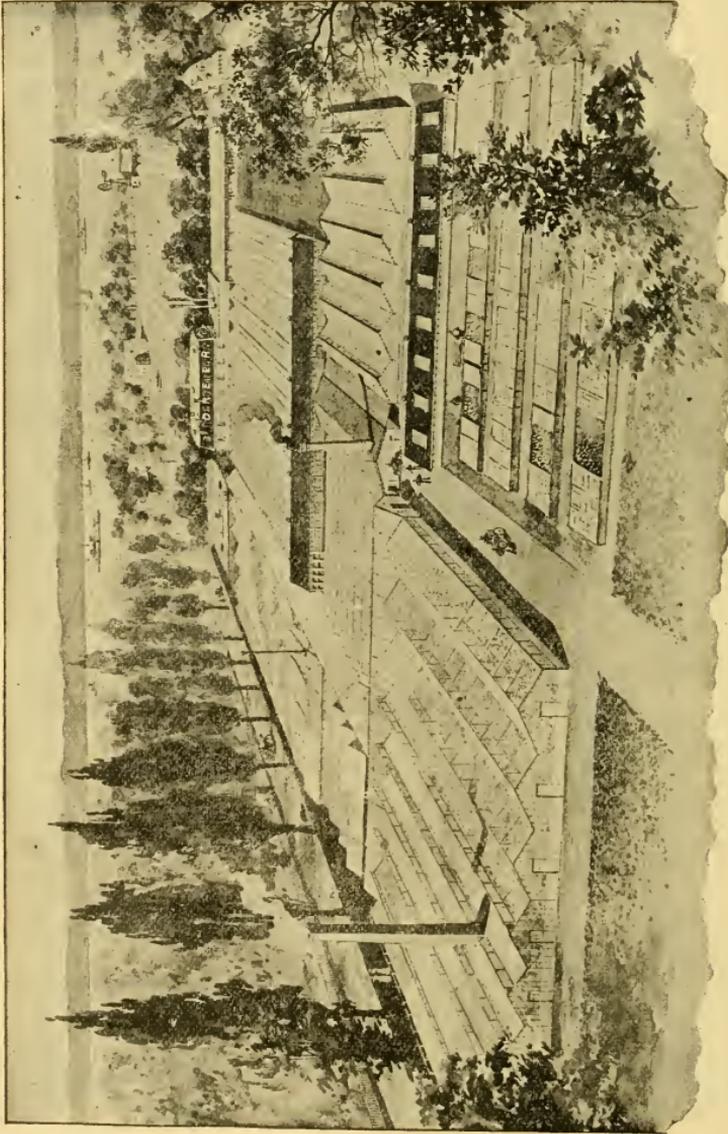

The one acre I have been describing is in the foreground at the left hand, where you see the chimney rising above. My impression was that one chimney and one set of boilers warmed the whole five acres; but as I now look at the picture I think I was mistaken.

over them. They have evidently planned these very much as I plan my quarter-acre under glass. The beds are of such convenient length that the sash can be piled up at each end without carrying them a very long distance. What do you suppose those neatly

kept beds contain just in front of the greenhouse, on the lower margin of the picture? Why, they are rows of strawberries where they are growing potted plants. If I remember correctly, the first row was our old favorite, Marshall; then I saw Brandywine, and other names familiar, on the neatly printed labels.

Norfolk Island pine. This pine attracted my attention both in California and in Florida. I have been told it is found nowhere else in the world except on that one island, and that it is quite difficult to grow them anywhere else outdoors. The minute my eye caught sight of several hundred of these magnificent little

GARDENING UNDER GLASS, BY THE ACRE.

Some of these labels actually came from The A. I. Root Co.

Near the upper right-hand corner was a sort of greenhouse covered with lath. It made me think of the pineapple plantations in Florida. This structure contained potted plants of the

trees, tastily arranged in beds like a systematic garden, I uttered an exclamation of surprise.

"Why! will these trees actually grow in the open air in this climate?"

"Not quite in the open air, Mr. Root. You see we have them partially shaded by the

slatted covering overhead. They will not endure a low temperature, neither can they stand the hot sun; but with this amount of shade we have discovered they do nicely, as you see."

Oh how I did want one of those beautiful plants! But it would be expensive to get it home, and then I am afraid it would never be cared for amid the rush of business round about the Home of the Honey-bees.

Oh, dear me! after going all the way to Philadelphia, and taking a whole week at that, I was admonished that, if I carried out my program, there was only about ten minutes left before train time. Our guide replied:

"Oh! but you *must* take a glimpse at the aquatic plants, if nothing more."

And then we went down hill a little piece where there used to be an ugly swamp or quagmire. Mr. Dreer had spaded out several square water-beds, and made walks between them on solid ground. Instead of a garden with raised beds, we had here a garden with sunken beds; and in these beds was every variety of water-plants, such as water-lilies—(so I should call them)—in full bloom, almost as large as a dinner-plate, and of almost all colors. Some of them had great green leaves floating on the surface of the water, as large as a small umbrella; and the *Victoria regia* had the edges of the leaf all turned up something like the edge of a jelly-tin, to keep the water from running over on top of the leaf; and this arrangement makes the leaf so buoyant that a young lady has safely stood on it without sinking.

I believe H. A. Dreer has the reputation of standing at the head of all growers of exotic plants in the United States; and in some respects I am inclined to think his glass structures are not excelled if equaled by those of any other man on the face of the earth.

#### MY PICKLE STORY.

Some time in the month of August I had been feeling that I must have a wheelride; so I arranged business for an absence of two days. But the Weather Bureau and barometer both said rain. In fact, it had rained a little—just enough to lay the dust; but it was cloudy, and the air cool, so I decided to start out and take the consequences. I got about 15 miles from home, and was enjoying myself hugely, singing, as I bowled along,

Praise God, from whom all blessings flow.

I changed my course a little to dodge the thunder-clouds; but it looked to me as if the thunder-clouds changed their course also. I was obliged to seek shelter once, then twice, and I began to meditate going back home. But the soil changed, and there was not very much mud. Then I came to a muddy streak, and became pretty nearly discouraged; but I got through it, and was congratulating myself that I was all right after all. Finally I came to a spot of very tenacious clay. The road had recently been worked clear over from one ditch to the other. There was not a chance to pick my way on either side; and the grass

up by the fences was soaking wet, and nearly two feet high. The wheel would have to go in the road or not at all. I got about half way through the bad spot, and finally the mud began to pile up; and so much collected on the frame I could scarcely push it; and when I essayed to walk, my bicycle shoes went down almost over their tops. I could neither go backward nor forward; and, in fact, I was in a "pickle." And this is the first part of my pickle story.\*

Some distance ahead a railroad crossed my road. I knew if I could reach that railway I could ride after a fashion between the rails. I managed to get out of this "Slough of Despond;" but by the time my wheel was cleaned off from that sticky clay, it was getting to be about supper-time; and the amount of strength I had expended in trying to force my way through and out of the mud made me about ready for supper, you may be sure. I got on along the railway track very nicely, and soon arrived at the little town of Smithville, Wayne Co., O. While I was eating my supper—that is, after my hunger was partly appeased—I noticed the people at the table were talking about pickles, and I was just thinking I might tell them something of one "pickle" that came in my experience that afternoon. Then they began discussing bushel boxes. Somebody said:

"Well, now, you may be pretty sure that Root's bushel box is all right. He is too careful a man to go ahead and make them by the carload unless he has them exactly right; and I tell you his box will stand law—you may be sure of that."

"I wonder how much business the Roots are doing this year, any way," said another. And then followed some other remarks that made me think I had better show my colors. Said I:

"Look here, friends; before you go any further perhaps I had better tell you that I am one of the Roots myself; and if I can help you in regard to the matter of the size of the bushel boxes, or any thing else, I am gladly at your service, especially since I have had such a nice supper."

Well, they were very glad to see me indeed; and when I told them I thought I had better stay over night they wanted me to go over and see their new pickle-factory. A great building has been erected. In fact, the whole thing was started since April. A great pickle combine in Cincinnati had volunteered to build a factory, equip it, and furnish a competent manager, providing the farmers round about Smithville would guarantee to grow 500 acres of pickles. The company agreed to pay said farmers 40 cts. a bushel for pickles not exceeding 3½ inches in length. All that were permitted to grow more than 3½ inches in length were to be sold for 12½ cts. a bushel.

Now, so far the contract was very pleasant; but before the company would go to work to

\*Constance accuses me of doing reckless things when off on my wheel—getting lost, and the like, in order that I may meet with spicy adventures. If she is right, I had found what I wanted this time, sure, for this adventure included spice, and a pickle besides.

put up the factory they demanded a donation of \$12.00 spot cash for every acre put out to pickles; that is, the man who furnishes the pickles must pay the company \$12.00 for each acre. The question naturally arose, "How many bushels of pickles can be grown on an acre?" Now, boys, we who have been in high-pressure gardening know something about it. If you have the ground just right, water just right, and *weather* just right, nobody really knows how many bushels of pickles an acre might produce. Six thousand dollars in cash is a good deal of money for farmers to scrape up and pay to the pickle combine. But I added:

"If you pay all the money that is required to build the factory and equip it, of course the institution belongs to the 300 or 400 farmers who furnish the money."

But somebody said very quickly, "Not so. The company will not go ahead and do a thing until we have raised the \$6000. Of course, we do not have to pay any thing another year. After the building is up and in operation then we get 40 cts. a bushel for our pickles, without any further payment on our part. They won't go ahead and put up the works any other way."

Now, friends, this does not seem to me quite right. It savors too much of the swindle that the *Rural New-Yorker* people have called the "creamery sharks." But on the other hand it may be that even a great pickle company would not want to furnish the capital to put up buildings in an out-of-the-way country place like this unless the patrons did something toward it. You will have to decide for yourself in regard to the right and wrong of it.

The building is 210 feet long by 150 feet wide, covered principally with barn boards, leaving cracks as in an ordinary barn. It is not necessary to have the building frost-proof, for pickles can not freeze when in the brine—at least, that was my understanding of the matter. The building contains 84 great tanks sufficient to hold 1000 bushels each. The tanks stand directly on the ground. They rise perhaps 3 feet through the upper floor. The pickles are taken in at the upper floor and dumped into the tanks. The farmers bring them in in bushel boxes; and here the discussion came in as to how large a box should be to hold just a bushel. I believe they adopted our bushel box. Pickles were coming in all along the evening, that had been picked during the day. Eight of these great tanks were already full; in fact, I saw 8000 bushels of pickles. It requires 40 barrels of rock salt to each thousand-bushel tank. After the salt is shoveled on, the tanks are filled with water, and the pickles are then safe until they are wanted to put into vinegar. Only the best grade of white-wine vinegar can be used in order to have pickles that will keep indefinitely without spoiling.

I inquired if there were not a good many farmers who would not succeed in raising even the \$12.00 worth from an acre. They told me there were, undoubtedly. In fact, some of the 500 acres have been abandoned already. There were other men who had got their \$12.00

back from their acre, and quite a little besides. I saw  $\frac{3}{4}$  of an acre right in the town. It was a rich garden soil. This had already furnished pickles enough to make a good thing of it; and with suitable weather they expect to have pickles for a month or more from the same patch. I asked about the largest yield they knew of from a single acre, and I believe somebody secured last year for the Creston pickle-factory 200 bushels from an acre; but this was doubtless by some one who is an expert in *high-pressure gardening*.

---

## OUR NEIGHBORS.

---

Beloved, let us love one another, for love is of God; and every one that loveth is born of God, and knoweth God. He that loveth not, knoweth not God; for God is love.—I. JOHN 4:7, 8.

These words were given us by the beloved disciple. I have often thought of him, not only as beloved but as a *loving* disciple. He was a brave and a bright man, but at the same time he was a peculiarly affectionate and loving one. We know he was *brave* as well as affectionate, because he was the only one of the twelve who pushed his way clear to the foot of the cross and stood there while his master was crucified. Yes, and he was rewarded by hearing that same beloved master bid him look after and take care of the poor bereaved mother. It was this John who has so much to say, sooner or later, about love. In the language of our text he winds up by saying, "*God is love.*" This fourth chapter seems specially devoted to love to God and love to each other. Now, let me confess to you that, in my earlier years, or, say, when I was a boy in my teens, I used to dislike to hear people talk about love. I do not know but I got something of a dislike toward the Scriptures because they have so much to say about love. From my point of view I thought it sounded "soft"—or, as the boys and girls say nowadays, "spoony." It might do very well for a mother to love her babe or for the babe to love its mother; and as I got along toward manhood I do not know that I had any particular objection to men and women loving each other; but I had a sort of feeling that they should talk about it when they were alone—try to keep it out of sight, as it were. When people talked about *men* loving each other it somehow or other conveyed the idea to me of men kissing each other; and, by the way, I suppose it is all right and just the fashion in some countries. Yes, even here in America—at least in some parts of it—I am told that male relatives, when they have not seen each other for a long while, have a habit of kissing each other as women do. Perhaps I might as well own up, while I am on the subject, that I am not yet converted to the fashion of promiscuous kissing, especially before folks. I once heard somebody say that a young woman should keep her lips for her husband or for her affianced lover; and I do not know but I would advise young men to do as much. Of course, this would not prevent a boy from kissing his

mother or sister, or allowing them to kiss him. There is not much danger that boys will become too well acquainted with their mothers and sisters. But let us now go back to this idea of loving each other.

When somebody explained to me that love meant *charity*, and charity meant love, or at least pretty nearly so, that put a slightly different construction on the matter. When I got to be a business man, and met other business men, I must confess I was inclined, as a good many business men are, to laugh at Christians, and to call them soft and silly. And, by the way, I still think that many of the expressions used in prayer-meeting — at least some of the stereotyped expressions that *were* used in prayer-meeting when I was a boy — are rather unfortunate. I think the Endeavor Society has done very much to change these things, and to make religion a practical common-sense *every-day* business matter. The sentence prayers that have been recently introduced are a grand improvement over the long stereotyped prayers of years gone by. May be I am "built that way," as the boys say; but a sentence prayer is often about all I can handle and comprehend at "one dose." I do not mean to say that those long old-fashioned prayers were not good. As I came to understand them better, after I became a Christian myself, I was many times impressed with the sublimity and grandeur of the thought expressed. It was often, however, "away up in the skies;" and when the good old deacon who uttered those sublime and lofty prayers cheated his neighbor in trading horses — why, I lost faith. I do not think this happened very often; but I do think the prayers of olden times were further away from the practical lives people lived then than the prayers of the present time are from the lives we are living. Some of the older readers of GLEANINGS can remember when I first got a glimpse of what the religion of Jesus Christ and Bible teachings really mean. Let me explain a little by an illustration right here.

A few days ago a man ordered some buckwheat, and asked particularly to have us tell him all about preparing the ground and sowing it, for he was entirely new to the business and wanted us to be sure to send him our circular on the cultivation of buckwheat, as it was so late in the season he would have to go at it at once and get the seed in as soon as received. The seed went promptly by the first train; but his request for that circular, and his explanation that he knew nothing about growing the plant, were entirely passed by. The clerk who received the money said she supposed they always put a circular in each bag of seed. The man who sent the seed said he thought the clerks in the office answered his request. Now, we have arrangements to prevent just such omissions as this; but some way or other his kindly request, accompanied with the cash, received no attention of any kind. Then he wrote again, explaining that his seed was received, but not a line of directions. I was a good deal stirred up, and remonstrated. I said that, on general princi-

ples, everybody who has a hand in business should have enough *love* for his fellow-man so that he would not do things of this kind, and I think still I am right about it. Genuine love toward our neighbor is worth more in business and everywhere else in life than any thing else *in the world*. I hope you have all read Drummond's little tract, "The Greatest Thing in the World," for he agrees with me exactly. Paul tells us in that wonderful chapter, that, if we give all our money to the poor, and our bodies to be burned, and have not this kind of love, it amounts to nothing.

Now, please excuse me for taking myself as an illustration. Years ago growing buckwheat was a hobby of mine, as you may know. I asked questions of farmers, got suggestions and hints from the readers of GLEANINGS, and put the whole of it in pamphlet form. I told you how to grow buckwheat before sowing wheat, so the buckwheat crop would cost almost nothing. I gave other short-cuts and discoveries to the man handling it. I watched the printers as they set up the type for that circular, and read it carefully again and again; and then I said that every purchaser of buckwheat might have one free of charge; and every time I saw a letter asking for that circular on growing buckwheat it gave me a pleasant thrill. I said to myself, "Won't this fellow be pleased when he sees in his circular all that is known about growing buckwheat, especially if he *wants* to know?" Well, for years past, whenever anybody has asked any sort of question about buckwheat, I have greatly enjoyed mailing him a circular. It would be *impossible* for me to forget any sort of request for it. It is my *hobby*, you know.\* Mrs. Root says this may be all true, but that I have no right to expect that *other* people will be "enthused" over each one of my hobbies. She said my clerks would have to be more than human if they were. I replied that it was only good sound common sense to be enthused over what brings you your daily bread and butter. Just another point:

My enthusiasm over how to grow buckwheat made me in love with people I had never seen. Of course, it was a kind of "love at first sight." Now, some people do not believe in love at first sight. I do. I believe we ought to feel in love with people we have never seen, every day. We ought to *fall* in love with them, not the first time we see the person, but the first time we see a *letter* from him. We should be *glad* to find somebody who *needs* help. In that beautiful parable

\* Two things occur right here. The first is, that no particular credit is due me in this matter, for it was a sort of negative virtue. It was the outgrowth of my strong bent for hobbies, and for riding them to the uttermost. The second point is this: There is no kind of advertising in the whole wide world that can compare with this sort. A man may get out circulars of the most expensive kind, and he may sow them broadcast, and spend heaps of money in advertising his business; but if he has not this love for his fellow-man—love at first sight, as I have called it—for somebody who wants to have his questions answered patiently, his advertising amounts to almost nothing. As I look back over the years, I believe no one thing has done so much to build up our business as this matter of answering patiently, promptly, and thoroughly every inquiry, even in regard to the little details.

about the good Samaritan, the summing-up of the Master's teaching was that every human being is our neighbor *when he is in trouble*. If somebody is in trouble or distress, the Christian should forget all former differences, all circumstances and conditions, and spring to his rescue. I am inclined to think people do that a good deal nowadays. If a man were among thieves we would go to his relief. If he were a thief himself we would help him first and have him arrested afterward—that is, if he needed arresting.

Now, when this matter of love is presented to the world in that light, nobody objects to it. If a man wants to hire a clerk, and he is told the clerk is a Christian, he may or may not think that is a recommendation. It depends upon whom the employer is; but when he gets acquainted with his clerk, and understands that his professing to be a Christian means that he is instantly "in love" with everybody who patronizes his employer's establishment, then the employer says, "All right; that is good. If that is what you mean by *religion*, give us the religion—send it along—can't have too much of it."

Just last week two of us were spinning along toward Niagara Falls. It was between four and five o'clock in the morning. All at once there was a sharp report, and the tire of my companion's wheel collapsed in an instant. Our program was suddenly broken up. Near by, however, was a ticket-office of the Niagara Electric Car Line. The agent said there would be no train until about nine o'clock that would carry wheels; but we could go to the Falls right away without the wheels. We finally decided to send our wheels back to Buffalo so that they would be in readiness for us after we had visited the Falls. The agent assured us they would be in Buffalo long before we reached there. On our return we saw our wheels right in front of the office where we left them. He did not send them down during the afternoon, and we waited for them till eleven o'clock at night in order to have a spin next morning. The wheels did not come. We wanted the agent at Buffalo to trace them by wire, but he said they could not do it. Then we wanted him to send a message by the car-driver, to be sure to bring the wheels in by the first car on the freight department. He could not do that—in fact, he could not (or *would not*) do *any* thing. When we were ready to leave Buffalo my companion made a trip back to La Salle and found the wheels just where they were left. He rode one and led the other all the way to Tonawanda. Now, the agent of this electric car line, it seems to me, was *remarkably* destitute of the kind of love the apostle John is talking about. After he had got our money he did not care any thing about us nor about our wheels. He would not even take the trouble to write a postal card saying the freight apartment was crowded with passengers, and had been ever since we left. The agent at Buffalo was the same sort of man. Notwithstanding the plain positive promise given us that the wheels would be in Buffalo before we were, he thought that very likely the best thing we could do

was to buy another ticket back to La Salle, and get our wheels home in any way we chose. You may say this company was responsible. Very likely; but it was easier and perhaps cheaper to go after our wheels and bring them home than to fuss or bother with the trolley company.

Heretofore I have been speaking of the *lack* of this Christian love: let us now turn to a pleasanter side of the matter. At a recent meeting of our Anti-saloon League, in discussing finances some wonder was expressed at the exceeding liberality of a young business man in the northern part of the State. A member present said:

"Yes; and strangest of all he is the son of a saloon-keeper."

But another person who was present promptly added:

"You are wrong, Bro. ——. He is not the son of a saloon-keeper. He used to be; but by the grace of God his father has dropped the business and will nevermore touch it again."

At this point a Methodist minister from Cincinnati (Rev. James P. Mills) arose and spoke something as follows:

"Dear brothers and sisters, notwithstanding the great amount of urgent business to be got through with this afternoon, I think we can afford to consider briefly the little story I have to tell you. While I was pastor in the city of ———, in the Northern part of Ohio, I once invited a young man to sing in the choir, whom I knew to be of intemperate habits. I discovered he had a fine voice, and was trying to get some chance to make an effort to save him, as his father was a saloon-keeper. He seemed pleased with the invitation, and sang exceedingly well. But the next day my best soprano singer tendered her resignation, saying that, when things had got to such a pass that men were invited to sing when their breath smelled so strongly of liquors that one could scarcely stand near them, she thought it was time to 'draw the line.' I was in a dilemma. I visited the young man, and had a long talk with him. In fact, I had several talks. He gave up his drinking, and continued to sing in the choir. He was finally converted, developed wonderful abilities for business and in other ways, and very soon persuaded his father to give up the terrible traffic, and now is a magnificent Christian worker; and out of the gratitude of his heart he is now giving regularly these generous donations to our cause."

Dear friends, what do you think of a love like that? As his former pastor spoke, we could hardly repress the tears. It was his love for the unlovable that prompted him to reach out and plead so earnestly for one in the hands of the enemy; and it was this same love in the heart of the rescued one that prompted him to reach out in a similar way for his old comrades; and, through our Anti-saloon League, for thousands upon thousands throughout our beautiful State who are going down to ruin in the way he would have gone but for that faithful pastor.

### STRAWBERRY-GROWING, NO. 2.

The beds I described in our previous issue will probably be used for growing plants to set out in the fields rather than for producing fruit, although by far the finest fruit can be secured by this same plan of sub-irrigation. When your beds are all full of plants, as they will all very quickly be providing you follow up the work without any neglect, you will probably need to set them out in the open ground. This plot of ground, be it large or small, should be thoroughly underdrained. The objection to sub-irrigation in the open air, I have already given. When you have potted plants to spare, put them out in ground well worked up and fertilized, in rows 4 feet apart. I would put the plants about a foot apart in the row. Run through them with your hand cultivators or horse cultivators, keeping the ground constantly soft and mellow, and free from weeds. When runners put out, pot them exactly as we described in the beds, using the jadoo fiber described in our Sept. 1st issue, on page 648.

In order to facilitate cultivating, every time you go to work potting plants, stretch a string on each side of the row. Now, have this string as near the mother-plants that are putting out runners as you can, and have just the young plants potted inside of the string, and yet arrange to have no two nearer than five inches from its neighbor. We do this in order that we may keep running the cultivator clear up to the line made by the string. The space between the plants must be kept mellow, and free from weeds, by some of the various hand weeders. Below is a cut of an excellent one for this purpose.

A HAND WEEDER FOR WORKING AMONG STRAWBERRIES.

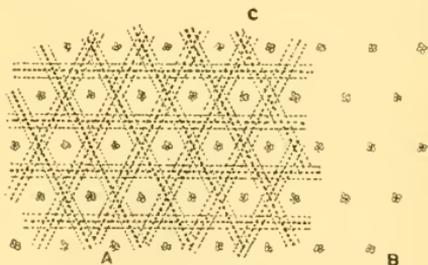

Now, the above arrangement is all right for growing fruit on the plan called the matted-row system, only we avoid letting the plants stand near together, on the plan that Terry recommends.

If you want to grow extra large nice fruit, there is a still better way; but there are several objections to this "better way." First, it is lots of work to do all the cultivating by hand. Second, it is lots of work to keep the runners off. Third, while you are growing fruit you can not grow plants for sale; and where the plants are rare and valuable, this is quite an objection. But, dear friends, you must remember that in strawberry-growing you can not grow the finest fruit and grow plants for sale at the same time. In bee culture you can not get great crops of honey and a great amount of increase of colonies in the same season. You will have to decide wheth-

er it shall be more valuable plants, or simply grow big berries and more of them. By the way, perhaps I should say that, while you are growing plants, all *fruit-stems* should be clipped off. You can not get the finest plants if you let the mother-plants that are sending out the runners bear fruit.

We will suppose, then, that you have in your sub-irrigating beds, and even in your very rich beds in the garden, kept off all blossom-buds. You have got to the point where you have hundreds or thousands of nice strong plants with great bundles of roots. They ought to be potted transplanted plants. What shall we do with them? Well, in the first place we want a piece of ground—the nearer square the better, although this is not particularly important. It should be at least an eighth of an acre; but if you have not that much we will try to get along with less. Have it well underdrained, then work it up fine and soft down 12 or 15 inches, or even 18 inches deep, if you can afford the expense. If the patch is small, get some expert gardener to spade it two "spits" deep, working in all the manure meanwhile you can get hold of. If you do it with horses, spread as much manure on the ground as can possibly be plowed under. Have a man follow the plow to pull the manure into the furrow; and then after the ground is plowed and harrowed, get some fine manure that will not clog the cultivators, and work in a lot more in the surface. Harrow it or cultivate it until it is fine and loose; then roll it until it is level; and I would take considerable pains to level it with a rake and shovel before rolling it.

In order to have surface drainage as well as underdrainage I would have a good deep ditch all around the piece, and have the ground slope gently from the center toward these outside ditches. Never let the water stand in puddles on your strawberry-patch.

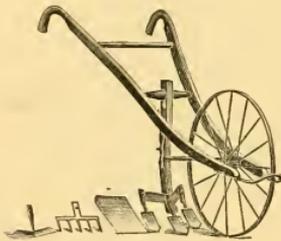

HOW TO PLANT STRAWBERRIES FOR HILL CULTURE.

Now with some sort of marker mark the plot, say from east to west, with marks as near 21 inches apart as you can make it. Any sort of mark that you can see plainly will answer. We now want to set the plants 2 feet apart in these marks; but you do not want them to come in squares. Each row of plants should "break joints" with the preceding row; then any three plants in the plot will stand in the form of a triangle; and this triangle will be 2 feet on each of its three sides. The diagram above will help us to get the idea.

You will see by the diagram that each plant is the center of a circle of six plants. The plants are equally distant from the center one and from each other, like the cells of a honey-comb, if you choose.

There are two reasons for planting in this way. When the plants are large and bushy, they entirely cover the ground much better than if they were planted in squares, and each plant has all the room it possibly can have. Second, you can cultivate them from right to left and diagonally two other ways—see marks made by the cultivator on the left-hand side of the cut above. With this arrangement every runner is to be clipped off just as soon as it can be seen. The plants are to be pushed into fruit-bearing. They are to make fruit and nothing else; and if you have never tried the experiment you will be astonished to see the size and beauty of the fruit grown in this way. All the great strawberry-growers all over the world are practicing this or a similar plan, where they want extra-fine fruit. If you mark the ground and put it out as above, your plants will be just about two feet apart from center to center.

Perhaps you may ask how to get these plants exactly on this equilateral-triangle arrangement. In the cut you will see three letters, A, B, C. These letters form an equilateral triangle. Make it as large as your plot of ground will admit. Take three strings of equal length; stretch one of them on the first row from right to left; then stretch the other two so they will meet at the point C. Now cut two sticks just 21 inches long, or the distance between the marks made by your marker. Use a stick at each end of the row to measure from the first string, and stretch the string every time you put in a row of plants. These rows are to be parallel, either with the line B C or A C. Set a potted plant wherever the string crosses a furrow-mark. The cultivating is all to be done with the hand cultivator or garden-plow pictured below.

COLE'S GARDEN-PLOW.

This plow has three teeth, as you will observe, and makes three furrows. The dotted lines between the plants in the cut are to represent these furrows. Run this cultivator through the plants in three different directions, as I have indicated, say as often as once a week; and be sure you run it once after every shower when the ground in the beds is in the best state to pulverize. Any boy will do it after you show him how, and he will think it is fun—that is, if the field is not too

large and the boy is not too small. If you have a spell of dry weather, such as we are having now, keep your garden-plow going, and it will almost take the place of watering. In fact, that is what our garden-plow is doing just across the way while I write these lines. Some kinds of plants are better suited for this hill-culture system than others; but almost any variety will do ever so much better when it has room and good cultivation, and does not have to make runners.

#### SWEET CLOVER.

From Bulletin 74, of the State of Ohio, we quote the following in regard to sweet clover:

Sweet clover was formerly included among those weeds whose destruction might be enforced under the statute. But this sweet clover, especially the white sort, is rated by many as a valuable forage-plant. In this respect, without discussing its merits, it properly takes rank with white clover and other cultivated forage-plants. A bee-keeper of the State had sown an area to white sweet clover (*Melilotus alba*), for his bees to work upon. Under the statute, as enforced at that place, the authorities, after notice, entered the premises and cut down the plants. Sweet clover, and other plants of value for cultivation, should not be included among the weeds to be destroyed. There is now the best of opportunity, as well as urgent demand, to put Ohio weed laws into adequate and permanent form. Suggestions as to plants that should be included will be given in the weed bulletin now in preparation.

It is refreshing to know that our experiment station at least recognizes the mistake it has made; and the bee-keeper who had his sweet clover cut down on his own premises will probably get the value of his crop paid back to him, without question.

#### SWEET CLOVER, AGAIN; SOMETHING ON THE OTHER SIDE.

On page 536 I see Geo. W. Fair's question, "Is sweet clover a noxious weed?" About sixteen years ago I sowed for a permanent pasture, red, alsike, sweet clover, and timothy. All grew to some extent. The second year I found nothing I had would eat the sweet clover. Horses, mules, cows, calves, sheep, and hogs all had access to it. I then plowed it up and cultivated the land and sowed the second year with mammoth, red, and alsike clovers, and timothy. Every year since, I have cut the sweet clover around the fences from one to three times. It has been my aim not to let any go to seed. I did the work myself. To-day I have been at it for the second time in 1897. I wrote to the *American Bee Journal*, stating my experience after I had tried it a few years, asking as a favor to notify the farmers. The answer was, "Your experience differs from that of others." Mr. Editor, if you will try to exterminate it for two or three years on a short piece of roadway or from fence-corners, you will be convinced. It is in Warren, Benton, Fountain, and Montgomery Counties; and on the highway, when stock is allowed to run, it is three feet high, while grass is quite short. In the closed counties the supervisors of the roads have it cut. I have talked to many of the farmers, and all condemn it as a weed. You say, "Teach your neighbors to make hay of it." Fence it off and turn cattle in, and let them starve. You say, "If you really want to get rid of it, wait till spring." Rot! If you want to get rid of it, don't let it seed; don't sow it. As for passing this journal around in the above counties, I wish to be excused. You may do that. I had it this year four feet high in pastures spoken of above. You seldom see catnip in pastures or in cultivated fields. I have received many benefits from the bee-papers, but it was through their influence I sowed sweet clover.

The seed may have a market value, but so has mustard seed; yet not many persons would advise farmers to sow mustard seed along the highway, to the detriment of others. I can show you sweet clover in the highway not as much molested by the stock that run there daily as is the mustard. Yes, I make mistakes, but you have made one that has done much damage to the farmers, and has been the cause of much hard

feeling toward the bee-papers. I believe that farmers will continue to blame any one who advocates the spreading of the noxious weed, sweet clover. Do you find mustard or mullin in your straw/erry-patch at fruiting time? Here, and in Central Illinois, where we can grow any of the usual hay and grasses, we have no use for it, and I don't think much of any one who will advocate it. He is only making enemies; and it appears to them that he does it for gain. The question Mr. Fair asked is, how to eradicate it. If you know, tell us. I confess my twelve years' labor have not done it. I am glad I have not let it spread on my neighbors, and have it confined to the one pasture and the fence-corners.

J. A. JOHNSTON.  
Green Hill, Ind.

I have given the above because I wish to have a fair hearing on all sides of the question. But I must still think our good friend Johnston has not exactly got the harg of the plant. I can not believe it possible that his horses and cattle are so different from those found elsewhere. Whenever I am away from home I am always watching to find a place where sweet clover seems to be crowding something else, but I have not found it. It is not in cultivated fields, it is not in pasture-lots, and I have never seen it in meadows. If it should get in with hay, especially if cut early, I can not imagine a horse or cow that would pick out the timothy and common clover and leave the sweet clover. So far as I can discover, it seems to occupy unused waste places, such as the banks along our railways, and roadsides where stock is not allowed. Where there is excellent feed along the roadsides, the cattle may choose the grass and clover first, because they have not learned to eat the sweet clover.

#### HOW TO GET RID OF SWEET CLOVER.

In the first place, cut it down before it produces seed, the same as you would any other plant. Second, turn on stock in the spring if practicable, and put enough stock in the field so they will eat up the sweet clover before it can go up to seed. Third, plow it under before it produces seed. Some one of the three above ways can almost always be found practicable. The principle difficulty will be in the fence-corners, where no stock is kept, or on railway ground; but as it has never yet got over into cultivated fields adjoining railroad ground and roadsides, on our premises, I can not understand how it should do any appreciable damage in any locality, where confined to these waste places. I am continually watching for it in my travels; and just as soon as I can find a place where it is detrimental to growing crops, pasture lands, or meadows, I will gladly report.

#### MULBERRIES—WET OR DRY LOCATIONS.

On page 535 you say that the Downing mulberry is like the willow. You will find yourself wrong in that. The mulberry does best upon dry clay ridges or well-drained land. There are, on the farm where I am writing, over 300 of those trees planted for a wind-break for the apple orchard, and some of them were planted on low land, and near the willow. The mulberry-tree died out on the wet land, while the willow died out on the high dry land. The mulberry will stand plenty of water if the drainage is good. You speak of the taste of the mulberry. You will find that trees from the same nursery differ very much in their fruit, ranging from very sweet to very acid. I find a great difference in the fruit of trees that are growing side by side, as well in the size of the fruit as in the taste of it. In all the 300 or more mulberry-trees on the farm here I find only one tree

whose fruit to me tastes like the mulberries which grew in New York—the ones I ate when I was a boy. I find that the best fruit is on the high and dry land, and remains upon the tree longest. I do not write for publication, but to let you know how it works here to plant the mulberry-tree on low or wet land.

Cuba, Kan., Aug. 6. WM. H. FAGERTY.

You are doubtless right in regard to the mulberries. The tree I spoke of near the little fountain was situated right over the under-drain. The ground was kept damp around the roots of the tree during dry weather; but the drainage was so perfect there could never be any standing water. I am inclined to think you are also right in regard to the quality of the fruit; and it would be nothing strange if we should be obliged to resort to grafting as we do with peaches, apples, and other fruit, to insure having the best results. Now, then, have we a nurseryman who offers mulberry-trees grafted with select choice fruit?

#### HIGH-PRESSURE GARDENING, ETC.

It was a cruel disappointment that the department of "High-pressure Gardening" was omitted in Aug. 15th GLEANINGS. Helpful hints are contained in these articles, that benefit hundreds of your subscribers. A better word would be *friends*.

I. DONNELLY.  
Indian River, Mich.

Why, friend D., there was "High-pressure Gardening" in the August 15th number, although I did not put in the heading. I told about the cold-frame plants at Mr. Miller's, the onions at Mr. Atwood's celery-farm, the potatoes at Wilbur Penn's, etc. But I thank you for your suggestion, and will try hereafter not to omit that particular "dish" from my semi-monthly bill of fare.

#### Special Notices in the Line of Gardening, etc.

By A. J. Root.

##### STRAWBERRY-PLANTS FREE TO EVERYBODY WHO SENDS \$1.00 FOR GLEANINGS.

I actually forgot to say to the friends, in our last issue, that I would continue sending the Darling strawberry-plant postpaid to every one sending us \$1.00 any time this fall; and as we now have a stock of plants of the Earliest, as well as Darling, you may have either one. Remember, a transplanted potted plant in jadoo fiber, postpaid by mail, free of charge, to everybody who sends us \$1.00 for GLEANINGS this fall. It probably would not be worth while to try to winter them over after October unless you have a greenhouse, cold-frame, or similar protection. As for ourselves, by the aid of glass we expect to keep growing and potting these valuable plants clear on till Christmas.

##### WHAT CROP TO PUT OUT IN SEPTEMBER.

Well, it is just now time to sow Wakefield cabbage-seed to get plants of the right size to winter over in cold-frames. It is also just the time to start Grand Rapids lettuce to have nice lettuce for Thanksgiving and the holidays. In our locality here in Northern Ohio, it is just the time to sow wheat or rye; and if you have sheep or stock to use the feed, it is just the time to sow dwarf Essex rape. Remember, this will stand almost as much frost as wheat and rye. Sow a piece of it where the poultry run, and it will give them green feed clear up to Christmas, and may be later.

If you put out strawberry-plants now, you must have potted plants, or have your ground sufficiently rich so they will get rooted well enough to stand the freezing and thawing. Our special strawberry circular will be mailed free of charge.

Of course, you do not want to forget to try hardy onion-seeds put in the open ground this fall. We succeed nicely with the American Pearl and Prizetaker. And, by the way, there has been an unusual demand

this fall for Egyptian onion-sets. We are entirely sold out of top sets, but we have a great abundance of bottom sets, or onions that have split up. These are just as good for planting, and some people think better than sets. Price \$1.00 per bushel. See price of onion-sets, page 6:7, Sept. 1st issue.

Radishes put in good rich ground in the open air will usually make a nice crop before freezing weather; and the best variety for this purpose is the Chinese Rose Winter. And now is the time to put in spinach for wintering over, in most localities.

Now is the time to sow seven-top turnip-seed for plants that will winter over. But these make no root, but furnish greens in the spring, and a little later, almost the first blossoms for honey. It comes in between fruit-blossoms and clover. If you are going to try it, it should be put in at once.

SEED POTATOES FOR 1898.

At present writing Sept. 15, nobody can tell definitely just what potatoes are going to be worth; but I have taken the liberty of offering all the varieties mentioned below, except Manum's Enormous, at an even dollar a bushel, or \$2.50 a barrel; and as they are worth this much in many localities for table use at the present time, I think our prices are very fair. The second size of any of these, until they are sold out, will be just half the amount. As we always run short of these second size long before spring, it might be well for you to put in your order now if you want them. I have just examined the potatoes raised by T. B. Terry, Wilbur Penn, and others in their neighborhood, and I am very glad to tell you they are nice and clean, and so far as I could learn, not a rotten potato has yet made its appearance anywhere in this locality. We should be pleased to send you samples by mail at prices given in the table, if you want to see them before buying.

We have now a few Danzenbaker hives in the flat, and made up and painted, ready for bees, for those who will order at once. Some may desire to transfer colonies from other hives so as to be ready for next season. Mr. D. says he expects to transfer 50 colonies this fall into his new hive; and another party is going to transfer as many more.

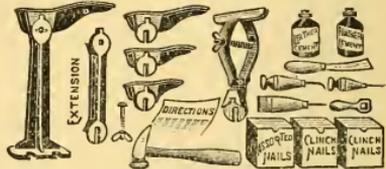

HONEY MARKET.

We are having a very fair demand for honey, both comb and extracted. We have a good supply of comb on hand and engaged, both fancy and No. 1 grades; are also prepared to furnish buckwheat comb honey. In 100-lb. lots and upwards, in original crates, we ask 13 cts. per lb. for fancy, and 12 cts. for No. 1; 11 cts. for fancy buckwheat, and 10 cts. for No. 1. Large lots for direct shipment quoted on application. We have a variety of extracted honey to offer. Willow-herb honey was almost a failure this year. We have secured nearly a ton of it, somewhat mixed with clover, which is still in Michigan. We offer this in 5-case lots (20 lbs. to a case) at 6 cts.; can supply water-white California honey or clover at the same price. Light amber California at 5 1/2 cts. in 5-case lots; smaller lots at

1/2 ct. more. We have also two barrels of the Florida tupelo honey, which is very fine; shall be pleased to hear from those in want of honey.

GLEANINGS FOUR MONTHS FREE.

We wish to extend our subscription-list by several thousand names during the next few months. As a help toward that end we offer the remainder of the year 1897 for 25 cts. To those who send early we will mail the two August numbers, as long as we have a supply, as well as the remaining four months of this year. Will not many of our readers bring this offer to the attention of their neighbor bee-keepers who are not taking GLEANINGS? As an inducement to you to do so we make the following liberal offer:

ROOT'S HOME REPAIRING OUTFIT NO. 2.

We sold this outfit for years at \$2.00, and that is still the list price, and price at which it is usually sold. About a year and a half ago we reduced the price to \$1.50, and again last spring we made it \$1.35. We have quite a number of these outfits on hand which we desire to get into your hands, where you can make them valuable in various kinds of mending. We will furnish one of these outfits, together with GLEANINGS for the rest of this year, for the price of the outfit alone—\$1.35. Now, if you can induce your neighbor to accept the offer above, put \$1.10 with the 25 cts he gives you, and send to us and we will ship you one of the outfits. If you wish to renew your own subscription at the same time, send us \$2.25 for GLEANINGS one year, to yourself the rest of this year (4 or 5 months) to a new subscriber, and the No. 2 repairing outfit. Or if you can not secure the new name we will send the outfit, with GLEANINGS one year, for \$2.00, the price you would ordinarily pay for the outfit alone. Please remember that, if you are in arrears on your subscription, all arrears should be sent in addition, as this special offer is made for subscriptions paid fully in advance.

CONVENTION NOTICE.

The Southeastern Tennessee Bee-keepers' Association will hold its annual session at Cookson's Creek, on Friday, October 1st, 1897, beginning at 9 o'clock A.M. Bee-keepers are earnestly requested to be present. The program foreshadows entertainment for the most fastidious. W. J. COPELAND, Sec. Fetzeron, Tenn., Sept. 3.

THE GLEANINGS CONTRIBUTION FOR THE STARVING PEOPLE OF IPDIA.

Since our last report we have received from Will Ellis, St. David's, Ont., Can., \$1; J. W. Margrave, Hiawatha, Kan., \$1, which has been forwarded as per following receipts:

- BOSTON, July 3. The American Board of Commissioners for Foreign Missions acknowledges the receipt from Chas. Booth, \$5; Albert Eckerman, \$1, and Will Ellis, \$1.
- Also, July 2, the American Board of Commissioners of Foreign Missions acknowledges receipt of \$1 from J. W. Margrave, Hiawatha, Kan.
- We have also received from C. A. Bunch, Nye, Ind., \$3.

The strawberry plants I received of you are doing well. Last year, from 20 rods of ground I sold \$30.00 worth, gave away \$14.00 worth, used in family \$16.00 worth, making \$60.00—very good. They were Haverland, Warfield, Sharpless, Crescent, and Parker Earle. West Hoosick, N. Y., Sept. 4. WM. P. ABBOTT.

The Weed foundation is the nicest I have ever used. It seems to be very tough, even at a temperature of 85 degrees—something I have never noticed in any other foundation I have ever used. J. E. MOTTER, JR. West Alexandria, O., June 16.

## CLOSING-OUT SALE

At Greatly Reduced Prices.

I have one hundred good Italian queens that must be sold within next two weeks to close up business for the season. Price each, 50c, or 10 for \$1.00. Can send either light allino strain or dark leather color. If you have old queens—hybrids or blacks—you wish to supersede, this is a rare chance to do so cheaply.

Address

W. W. CARY, = Colrain, Mass.

25 Cts. PER YEAR!

for the best agricultural and stock-breeders' paper published.

Stuart's Agriculturist.

Agents wanted! Bicycles, etc., free. Address

WHITWORTH BROS.,

### GERMAN CARP WANTED.

1000 this year's; 100 or more last year's. Prices must be reasonable. Send offers to

DR. W. M. MOERSHEL, Homestead, Iowa.

Carp to be shipped in August or September.

### No cheap Queens to sell; but the best.

Golden 5 band, or 3 band from imported mother. Untested, 75 cts.; tested, \$1.00.

L. BEAUCHAMP, Box 613, San Antonio, Texas.

### What They Say about the Poulder Honey-jars.

BAVONNE, N. J., July 31, 1897.

Dear Sir:—In reference to the way in which you pack your jars, would say that we kept a strict count on the last shipment, making a memorandum of the number of broken ones in each case when opened. We found upon finishing the 1200 jars that we had 14 one-pound and 2 half-pound broken, or an average of one and one-third jars to the case. This is a big improvement when we look back to the time when we received them packed in straw from other houses, with all the way from 4 to 10 in a case broken. Wishing you and your business success, we remain

Yours truly, HOLDING BROS.

### MAKE MONEY! YES. HOW?

With poultry, bees, and flowers. Particulars free.

COOK BROS.,

Scio, - Harrison County, - Ohio.

QUEENS, Either 3 or 5 banded, 60 cents each; 6 for \$3.00. Nuclei and supplies cheap.

CHAS. H. THIES, Steeleville, Ill.

FOR SALE.—Italian queens, 50 cents each.  
MRS. A. A. SIMPSON, Swarts, Greene Co., Pa.

## Dovetailed Hives,

Sections, Extractors, Smokers, and every thing a bee-keeper wants. **Honest goods at close honest prices.** 60-page catalog free.

J. M. JENKINS, Wetumpka, Ala.

### Don't Neglect Your Bees.

Bee-keeping may be made uniformly successful by judicious feeding. It is just as important with bees as with other stock.

Success in feeding depends very much on the feeder used. When you have tried the

Boardman Atmospheric Entrance-feeder

you will be convinced of this.

For descriptive circulars and price list, address

H. R. BOARDMAN, East Townsend, Ohio.

### THE A. I. ROOT CO'S Shipping-cases for Honey,

AT THEIR PRICES—THE FINEST MADE.  
CASH FOR BEESWAX.

M. H. HUNT, Bell Branch, Mich.

QUEENS. Untested golden beauties, or 3-banded, 45 cents each. Write for wholesale prices. I have good bees. To be convinced, order a sample queen. This is a money-order postoffice.

DANIEL WURTH, Falmouth, Rush Co., Ind.

FOR SALE.—500 very choice Italian red-clover queens at 70 cts. each; 1/2 doz., \$2.80; tested, 75 cts. Our bees made 50 lbs. per colony of red-clover honey this season. 15 years' experience in queen-rearing.

LEININGER BROS., Ft. Jennings, Ohio

## Wants and Exchange Department.

WANTED.—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules.

ANTHONY OPP, Helena, Ark.

WANTED.—To exchange the world-wide encyclopedia (Encyclopedia Britannica Revised) comprising 15 vols., bound in green silk, weight 40 lbs., 6302 pages, for white-clover honey or offers.

A. H. KANAGY, Milroy, Mifflin Co., Pa.

WANTED.—To exchange 28 new volumes Encyclopedia Britannica for honey. O. H. HVATT, Shenandoah, Page Co., Iowa.

WANTED.—To exchange some fine collie shepherd pups for any thing useful. I also have some fine pigeons and a fine blood-hound pup to trade.

CLAUD BRILLHART, Oakwood, Paulding Co., Ohio.

WANTED.—To exchange 16-section non-drip cases at Root's prices, laid down at your station, for fancy comb honey at prices to suit the times. Also second-hand 60-lb. cans, 2 in a case, valued at 25 cts. per can, freight paid, for gilt-edged extracted honey. Special price on quantity lots.

B. WALKER, Evert, Mich., or 541 Van Buren St., Chicago.

WANTED.—To exchange Plymouth rocks or white leghorns for queens, incubator, or offer.

J. FERRIS PATTON, Newtown, Ohio.

**THE S. & H. CO.**

desire to enter into correspondence with all contemplating the purchase of anything in their line. They think they have one of the most complete assortments of strong, smooth, healthy,

## FRUIT AND ORNAMENTAL TREES

Small Fruits, Vines, Shrubs, Roses, Bulbs, Hardy Herbaceous Plants, Greenhouse Stock, Etc., on the market and invite all buyers to come and see for themselves. They are to be found at the old stand where they have labored faithfully for the past 43 years to build up a reputable business. Catalogues free.

Address **THE STORRS & HARRISON CO., Box 8, Painesville, O.**

## IF YOU WANT BEES

that will just "roll" in the honey, and that are wonderful red-clover workers, also gentle to handle, and exceedingly hardy, then try **MOORE'S STRAIN OF ITALIANS**, the result of 18 years of careful breeding.

Warranted queens, 75 cts. each; 3 for \$2.00; per doz., \$7.00; select warranted, \$1.00; 3 for \$2.50. Safe arrival and satisfaction guaranteed. Circular free. Those who have never dealt with me I refer to A. I. Root, who has purchased of me over 850 queens.

**J. P. Moore, Morgan, Pendleton Co., Ky.**

**MUTH'S HONEY-EXTRACTOR,  
SQUARE GLASS HONEY-JARS,  
ROOT'S GOODS AT ROOT'S PRICES,**

Bee-keepers' Supplies in general, etc., etc. Send for our new catalog. "Practical Hints" will be mailed for 10 cts. in stamps. Apply to

## Honey Column.

### CITY MARKETS.

**NEW YORK.**—*Honey.*—Comb honey has been arriving for the past few days very freely so that the market at present is well filled. On account of the weather being a little warm, honey is selling a little slowly. We quote our market as follows (shade prices from 1 to ½¢ per lb. on large sales): Fancy white clover, 12@12½; No. 1 white clover, 10@11; buckwheat, 8½@9½. Extracted honey, California, is selling quite lively at the following prices: White, 5@5½; light amber, 4½@5. Southern is very dull, and is selling from 50 to 55. New York State extracted honey, not much in demand as yet. Beeswax receipts rather light. We quote 25½@26; must be very fancy to bring outside price. Write us before shipping.

FRANCIS H. LEGGETT & Co.,  
New York.

Sept. 25.

**ALBANY.**—We hardly think there is as much honey on the market as there was a year ago at this time, but there is ample to supply the demand. We think prices will range a little higher than last year, as business prospects are brightening up. White clover, 11@12; fair to good, 10@11; buckwheat and mixed, 8@9. Extracted in light demand.

CHAS. McCULLOCH & Co.,  
Albany, N. Y.

Sept. 25.

**DENVER.**—We find our honey trade improving since the first of the month, especially with extracted. Comb honey was never known to sell as low as it is now, and it is the farmers and small bee-keepers that have ruined the price by selling to the stores at any price they were offered. The highest possible price we can quote fancy white comb honey is 10c; and No. 1 white at 9c; No. 1 white extracted, 4½@5; good clean beeswax, 25. R. K. & J. C. FRISBEE,  
Lock box 1014, Denver, Col.

Sept. 6.

**MILWAUKEE.**—The receipts of new-crop honey are beginning to come in, and the quality improved. The supply is not equal to the legitimate wants of our trade, and with improved conditions of trade we expect to sell more than last year. The demand so far is not heavy, but we feel, to encourage our shippers, that it will come. We quote white No. 1 comb 1-lb. sections, 11@13; amber, 8@10; white extracted, in bbls. and kegs, choice, 4½@6; dark or amber, in bbls. and kegs, 4@6; beeswax, 25@27. A. V. BISHOP & Co.,  
Milwaukee, Wis.

Sept. 6.

**CHICAGO.**—Comb honey sells a little more freely, yet receipts are in excess of sales, and some shippers of small lots get impatient at what seems a long delay in getting returns, yet it can't be forced without detriment to general interests. Best grades of white comb bring 12c; white but objectionable, 10@11; amber and dark, 7@9; extracted white, 5@6; amber, 4@5; dark, 3½; beeswax, 26@27. R. A. BURNETT & Co.,  
163 South Water St., Chicago, Ill.

Sept. 6.

**COLUMBUS.**—Fancy white clover, 12½; No. 1, 11. Arrivals no heavier; demand better, but no improvement in prices. Large sales are impossible, and as yet are having no trade from near-by towns.

THE COLUMBUS COMMISSION & STORAGE Co.,  
409-413 N. High St., Columbus, O.

Sept. 6.

**CINCINNATI.**—Demand is fair for extracted and comb honey, and considerable honey is arriving, but not much more than is justified by the demand. As the range of prices, we quote for choice white comb honey 11@13. Cincinnati is no market for dark comb honey. Extracted sells for 3½@6, according to quality. Beeswax is in good demand at 20@25 for good to choice yellow.

Sept. 7.

CHAS. F. MUTI & SON,  
Cincinnati, O.

**DETROIT.**—Best comb honey, 10@11½; best extracted, 5@5½; beeswax, 25@26.

Sept. 7.

M. H. HUNT, Bell Branch, Mich.

**ST. LOUIS.**—We have no special remarks to make in regard to the honey market. Prices are nominal at last quotation. Weather is too hot for the sale of honey. Beeswax is a little firmer, being 24½@25 for prime stock.

Sept. 9.

WESTCOTT COMMISSION Co.,  
213 Market St., St. Louis, Mo.

**CLEVELAND.**—We quote selling to-day as follows: Fancy white, 13; No. 1 white, 11@12; fancy amber, 10; No. 1 amber, 8@9; buckwheat, 6; fancy white extracted, 6½; beeswax, 25. A. B. WILLIAMS & Co.,  
80-82 Broadway, Cleveland, Ohio.

Sept. 8.

**NEW YORK.**—New-crop comb honey arriving more freely and demand good. We quote fancy white, 12@13; off grades white, 10@11; buckwheat, 9@10. California extracted selling fairly well, while all other kinds are neglected. We quote California white, 5@5½; light amber, 4½@5; Southern, 50@55 per gallon; beeswax dull, and easy at 26.

Sept. 7.

HILDRETH BROS. & SEGELKEN,  
120-122 W. Broadway, New York.

**PHILADELPHIA.**—Honey coming in freely, and some call for comb, but the hot weather of the last few days stops sales somewhat. We quote fancy white comb 13½; No. 1 white, 11@12; no dark comb in yet; white extracted, 5½@6; amber, 4@5; beeswax, 25. We are producers of honey; do not handle on commission.

Sept. 7.

W. M. A. SELSER,  
10 Vine St., Philadelphia, Pa.

**BOSTON.**—We quote our honey market as follows: Fancy white comb in 1-lb. sections, 14; No. 1, 12@13; white extracted, 7; light amber extracted, 5@6; beeswax, very light supply, 27. Good demand.

Sept. 7.

BLAKE, SCOTT & LEE,  
Boston, Mass.

**KANSAS CITY.**—We quote No. 1 white comb, 11@12; fancy amber, 10@11; No. 1 amber, 9@10; fancy dark, 8@9; No. 1 dark, 8; white extracted, 5½@6; amber, 4½@5; dark, 4@4½; beeswax, 22@25.

Sept. 7.

C. C. CLEMONS & Co.,  
Kansas City, Mo.

**MINNEAPOLIS.**—No. 1 remains same—no change, 11@12. Other grades accordingly. Supply equal to demand.

Sept. 6.

S. H. HALL & Co.,  
Minneapolis, Minn.

**FOR SALE.**—25 bbls. extracted pure white-clover honey, very light in color, and of finest quality, at price as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

**FOR SALE.**—A lot of good extracted clover honey in 60-lb. cans.

J. NO. A. THORNTON, Lima, Ills.

**WANTED.**—To buy quantity lots of fancy comb honey in non-drip cases.

B. WALKER, 541 Van Buren St., Chicago.

**FOR SALE.**—Alfalfa honey, light amber, in carload lots. 3½ cts. per lb.; sample, 10 cts.

JOHN NIPPERT, Box 1051, Phoenix, Arizona.

**FOR SALE.**—Pure honey—Clover, extracted, 6½ cts. per lb. Buckwheat, extracted, 4½ cts. per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City.

**FOR SALE.**—Buckwheat extracted in 50 and 210 lb. packages f. o. b. for 4½¢ a lb.

W. LAMAR COGGSHALL, West Groton, N. Y.

**FOR SALE.**—1000 lbs. of fine buckwheat comb honey.

D. F. LASHIER, Hooper, Broome Co., N. Y.

**FOR SALE.**—Choice honey, 6000 lbs. in well-filled sections, at 9½¢ per lb.; extracted, 4½¢.

W. C. GATHRIGHT, Dona Ana, N. M.

# A Tested Queen and the Review for \$1.50.

I have a large number of nuclei containing fine tested Italian queens of this year's rearing, and have decided to use them in helping to build up the circulation of the **Review**; hence offer a queen and the **Review** one year to new subscribers for only \$1.50. **Review** alone, \$1.00; queen alone, \$1.00. If several queens are wanted, write, and the price will be made according to the number. As a rule, orders are filled by return mail, and there is never a delay of more than three or four days, and that on large orders.

W. Z. HUTCHINSON, Flint, Mich.

# \$100

Given as **BOUNTIES** to purchasers of the improved Danz. Hives and Sections. For particulars see p. 64, of my book, "Facts about Bees." Sent Free for 2-cent stamp. Address  
**F. DANZENBAKER, Washington, D. C.**

**Italian Queens**, either golden beauties or 3-banded imported stock. Tested, 75c each; untested, 50c each; select tested, \$1.00 each; breeders that produce pure stock, of either variety, \$2.00 each. P. O. M. O. office, Iavaca. **E. A. SEELEY, Bio mer, Ark.**

Philadelphia Office of  
**THE A. I. ROOT CO.,**  
 10 Vine St., Philadelphia, Penn.

Now is the time to order  
**Shipping-cases, Winter Cases, Chaff Division-boards, etc., etc.**

Order from catalog; prices are same as from factory.

## Shipping-cases.

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA.** Immense stock. All orders for cases or other goods shipped by return freight. Address

**JOS. NYSEWANDER, Des Moines, Iowa.**

**BEE CULTURE**

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

Published by THE A. ROOT CO.  
 \$1.00 PER YEAR MEDINA, OHIO.

Vol. XXV.

OCT. 1, 1897.

No. 19.

**STRAY STRAWS**  
 FROM DR. C. C. MILLER.

THE PLAN given by W. H. Eagerty, p. 666, for sowing sweet clover, is the best I've ever seen, especially having the seed tramped in by horses.

WHEW! but haven't we had a hot September—at least the first half? [Yes; and three days afterward there was a fall of 50 degrees in the temperature.—ED.]

SCOTTISH HEATHER, we are told on p. 663, abounds in New Jersey. Is there no mistake about this? Never heard before that it grew anywhere in this country.

ANY OPENING for ventilation that comes close to the sections hinders greatly their sealing at that point; but it has seemed rather an advantage for extracted honey.

BRO. A. I. ROOT, tell that high-pressure-gardening man who got 200 bushels of pickles from an acre to come to Marengo and learn how to raise pickles. John Boyle got 236 bushels from three-fourths of an acre.

MCINTYRE is right, p. 670, that stirring honey hastens granulation—one reason, probably, why extracted granulates sooner than comb. The Germans sometimes put honey through a sort of churning process to hasten granulation.

REFERRING to p. 671, I don't think I'd want to put a few cases of honey loose in a car, but I think that's what Mr. Niver said the railroads recommended; and when I distinctly asked Capt. Hetherington about it, I think he agreed to the same thing.

NORTHERN ILLINOIS had a good honey year. At a bee-keepers' convention at Freeport, 843 colonies were reported as yielding an average of 60 pounds each, nearly half of it being comb honey. [If you have told us, doctor, I have not seen whether you had a good honey year.—ED.]

How QUICKLY bees notice any change in appearance at a time when forage is scarce! Set a hive in a new place, or put an extra story on it, and promptly the robbers will interview it to find if there are weak places.

At the same time, a weakling not half so able to protect itself will be left untouched so long as there is no change in outside appearance.

NOWADAYS the bees are almost as good as a weather-cock. When the wind is from the north, a cloud of bees hovers about the south screen-door of the honey-room all day long. When the wind is from the south, not a bee is seen at the south door; but they're frantically trying to force an entrance at the north door.

J. A. BUCHANAN's plan of handling "only such grades of honey as will not candy, or are very slow to do so," is an excellent one for him; but what are those fellows to do who produce only alfalfa? Somewhere, somehow, the problem of candied honey must be met, and happy is that bee-keeper whose customers are trained to cope with it.

A PREVAILING VICE among preachers is using a story for illustration and leaving the story half finished. I read aloud p. 679, my audience giving best attention; but when I got through they insisted on my telling them whether that man ever got his buckwheat circular. I told them I didn't know, and now there's coldness in the family.

J. A. JOHNSTON, p. 682, is right to a certain degree. It isn't easy to kill out sweet clover in fence-corners and on roadsides. But then, it isn't any easier to kill out other weeds in the same places; and where the ground is plowed, sweet clover is no more troublesome than other weeds. Give sweet clover fits where it deserves it, but please be fair.

VERY SELDOM are the difficulties of grading shown up as well as they are on p. 673, and I doubt whether any set of grading-rules that can be relied on to buy and sell by can ever be formulated without a number of distinct specifications and the use of a good deal of language. [I do not like to give up the idea of getting a satisfactory set of grading-rules, but Mr. Calvert, our honey-man, has come pretty near knocking the notion all out of my head.—ED.]

W. H. EAGERTY, p. 666, advises me to spread section stuff on grass in shade rather than pour water on the grooves. But, friend E., I can't afford to wait till grass grows; and, besides, I wet a whole boxful before taking them out of the box, taking a very few min-

utes, and it would take a long time to spread sections out on the grass and then gather them up. Generally they don't need any wetting—only the few, if any, that have been left over from previous year.

SOME THINGS are to be discussed at the Nebraska State convention. Four of the topics are: "Some things I don't know;" "Some things I know;" "Some things I should like to know," and "Some things every one ought to know" about bee-keeping. [You ought to be there, doctor, to discuss the first of the quartet of subjects.—ED.]

C. H. DIBBERN says the plan spoken of in a former Straw, of putting a cone escape on the mother hive, will surely prevent after-swarms; but in 12 days hardly a bee will be left. The bees eat up all the unsealed brood, either from thirst or alarm at the field-bees not returning. I don't know how long Isaac Lundy leaves the escape on; but would it be necessary for more than eight days? Or how would it do to put it on in six or seven days after the first swarm, and leave it on three or four days?

F. A. GEMMILL, in *Canadian Bee Journal*, says he has had success wintering on solid sealed combs of honey, and quotes McEvoy as indorsing him. Others in same number object to it. [We have made a practice for years of giving solid sealed combs of honey, and putting them right into the brood-nest for winter stores. The fact that our loss for a number of years does not much exceed two per cent is pretty good evidence that the practice is not as harmful as some people think.—ED.]

THAT CORRECTION, p. 669, as to the way the queen makes the piping noise, is all right, and should have been corrected in ABC about ten years ago. But the other correction won't stand. According to the authorities, the bees laboriously masticate the wax with salivary secretion, which agrees with the statement of ABC. The only way they could get acid from the poison-sac would be through the sting. [Yes and no. Well, I don't know. I never saw a queen pipe yet but there was a decidedly tremulous motion to her wings.—ED.]

"WE EXPECT to make our hives next year so that the entrances will be an inch deep, and the full width of the hive.—GLEANINGS, p. 661. Good thing! Could hardly make it better, unless with every hive you give a township right to hoist the hive on four  $\frac{3}{4}$ -inch blocks. But, say! How are you going to enlarge the entrance? If by cutting away part of the front of the hive, I object. All my life I've had hives with entrances cut out of the hive; but since learning the comfort of dovetailers that will sit on one another bee-tight, no more of the old kind for me. [Hives will be left intact, and the entrance will be formed by the construction of the bottom-board, the same as formerly.—ED.]

THE NORTHWESTERN ASSOCIATION, which formerly held such successful conventions at Chicago, is to be revived. Urged by a num-

ber of bee-keepers, and indorsed heartily by the editors of the *American Bee Journal* and *Review*, a call has been issued for a convention, Nov. 10 and 11, at the New Briggs House, Chicago. As that is during the fat-stock show, also the horse show, fares will be low, and a good meeting expected. Say—who's coming from Medina? [I might come with some coaxing, but I can not tell positively at this early date whether I can leave then.—ED.]

"COMB HONEY was never known to sell as low as it is now, and it is the farmers and small bee-keepers that have ruined the price by selling at the stores at any price they were offered."—*Frisbee, Gleanings, p. 655.* "The farmers and small bee-keepers are our best friends," is the teaching attributed to Bro. Abbott, p. 670. All who have had your markets improved by poor honey thrown on the market at low prices, please hold up your hands. [The way you have placed the two ideas over against each other almost puts Bro. Abbott into the shade; but after our friends get through holding up their hands, I wish Bro. Abbott would stand up and explain more fully why the farmer bee-keeper is his friend.—ED.]

M. H. MENDLESON writes that he practices, with entire success, first putting on extracting supers, then sections. "The darker honey is extracted; by that time your hives are boiling over with bees, and are forced to go into the sections. The brood-apartment is generally crowded with brood." [I have been preaching that thing myself, and I am glad to know that I have such a "big gun" as Mendleson to back me up. My object in using extracting-supers to start was not to get rid of dark honey, but to get the bees started in supers. I find that they will go into extracting-supers sooner than into sections; and if they once get into the notion of going above they are more apt to keep on going up, even when the surplus arrangement has been changed to something they do not like quite so well.—ED.]

A DISCUSSION is on in the *American Bee Journal* as to the value of the bee-space. W. C. Gathright thinks where shade is scarce the bee-space protects against the sun. He says, "I once put out some hives facing south, and in almost every one the comb next to the wall of the hive on the west side of the hive melted down. I then turned the hives with the entrance to the east, and had no further trouble. The space between the end-bars and the end of the hives served almost the same purpose as a double-walled hive." [I have watched the discussion myself; and after looking over all the arguments on the other side, I fail to see one good reason why a bee-space should not be used; and on the other hand there are many reasons why it *should* be used. To abandon this bee-space in this day and age would seem to me like going back to the flail to thrash our wheat rather than to use the modern steam thrashing-machines. The most convincing fact to me is that those bee-keepers who use the bee-space produce as much honey per colony right along as the one

or two who think they can not use the bee-space; and, besides, there is a heap more comfort in working with the bees and taking off the honey. Why, the point seems to me to be hardly debatable.—Ed.]

"FULL OF PROMISE to apiculture" is the idea of breeding bees for longer tongues, according to Prof. Cook, p. 658. But when he says, "It will take long years, hence the necessity of great patience," I think he throws on more cold water than is warranted. Look at Dr. Murdock's bees with worker-cells, some of them as large as drone-cells, and consider the fact of the great inequality in the present length of bees' tongues. Say, Mr. Editor, just you offer for sale as good glossometers as they have in France, or better ones, and a whole lot of us will go to work at once; and instead of "long years" I believe the question could be pretty fully settled in three to five years; and no one would be quicker or gladder to say he was wrong than Prof. Cook. [Somehow I do not enthuse very much over the possibility of getting bees with longer tongues. A good many attempts have been made at it, but practically nothing has been accomplished. Perhaps if an experiment station could take hold of it something might be done.—Ed.]

#### BIOGRAPHY OF DR. JESSE OREN.

Another Banker Bee-keeper.

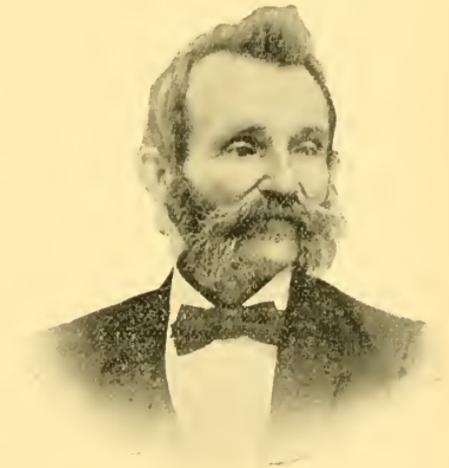

BY O. O. POPPLETON.

The late Adam Grimm will long be remembered as the "Banker Bee-keeper." It is not generally known that we have another man in our ranks, still alive, who divides honors with Mr. Grimm of having graduated from bee-keeping into banking, but has, I think, a much more interesting and unique personal history.

Dr. Jesse Oren was born Sept. 22, 1824, in York Co., Pa., which locality had been the home of several generations of his ancestors on both sides, some of whom suffered severely during the Revolutionary and early Indian wars.\* It would be very interesting to record some of their adventures, but lack of space prevents.

\* All his ancestors on both sides were born and reared in York Co., Pa., and owned farms adjoining each other. These farms were near the Susquehanna River—on the south side of the river, opposite Middletown. Just below Middletown are the rapids in the river, and it is considered very dangerous to attempt a passage by any ordinary boat. Middletown is situated at the junction of Sweet Arrow Creek with the river. Jacob Keller had gone across the river, and was attacked and pursued to the mouth of this creek. Ice was thick in both river and creek, and just grinding along prior to closing up for the winter. It seemed to be only a choice as to the manner of dying. Jacob Keller chose death by ice and water rather than to be captured. He rushed in among the ice, succeeding after a time in getting on top of a large cake of it, and went over the falls safely, and landed on an island about three miles below the falls. On this uninhabited island of about five acres of ground he remained nearly three days before the river closed and he was able to cross to the shore on the ice. The island has ever since been called "Keller's Island."

Dr. Oren's early life on his father's rocky Pennsylvania farm laid the sure foundation for his subsequent life of industry, frugality, etc., necessary for the success of his later life. Deciding that he must have a better education than could be had on the farm, he, when 16 years of age, bound himself out to a harness-maker, with the distinct agreement that he was to have a certain amount of schooling; but the agreement not being lived up to, he went first to Lancaster, O., and then to the Plainfield Academy, where the principal took him as scholar, knowing he was dollarless. From here he went to Johnstown, Pa., where he taught a school during the winter of 1842. In the spring he started for Oberlin College; but by chance he was stopped at Richmond, O., where a new college had just been started. Here he remained three years in alternate

DR. JESSE OREN.

study and teaching. Some of his experiences during this time were interesting and very characteristic, but space forbids giving them.† Hard study and work had broken down his

† He remained in Richmond, O., three years, all the time at study. At the end of five months Dr. Lorimer gave him a certificate of character, and sent him to Judge McCullough, who lived at the mouth of Yellow Creek, about three miles from Wellsville, O. Here he obtained a school at good wages, but soon learned that William McCullough, son of the judge (and at the present time superintendent of a railroad, with headquarters at Wellsville, O.), and John and William Hammond now and since, and during the civil war, John made his figure as an eminent physician) were to commence the study of algebra and geometry. As Mr. Oren had not studied geometry at all, he felt embarrassed, but nevertheless assigned them a lesson, and then went home to study it himself. As his school was but ten miles from Richmond, where it was well known he was unbooked in geometry, and as he felt the situation was a bad one, he determined to fortify himself by always hearing the lesson of the boys without having the book in his hands. In five months the boys passed through six books of Legendre without a miss or a fault. This will be news to Dr. John Hammond should he see this in print.

health, and he was sent home to Pennsylvania under sentence of death from consumption. Fortunately he fell under the care of a very able physician, who treated him for nervous disorder caused by overwork, instead of for consumption, resulting in a cure in a few months.

As a patient he became interested in the study of medicine, and adopted it as a life profession. For the next few years he was engaged in teaching, in obtaining a collegiate and medical education, and in extensive hospital work, finally being graduated as "M. D." at the Penn Medical University, of Philadelphia.

In 1854 he was one of a limited number of young American surgeons who entered the Russian medical service during the Crimean War. For the first few months he served in a large hospital at Backsissaria, some 12 miles north of Sebastopol; afterward in hospital No. 18 at Cherson, until the end of the war. This removal to Cherson was a promotion with much increased pay and privileges, and was by direct order of the Czar himself. Soon after Dr. Oren went on duty he and his superior, a German surgeon, had a controversy on some point of practice, resulting in a bet, and a victory for Dr. Oren. The idea of a young American doctor worshipping a veteran German surgeon was too good to keep, and it reached the ears of the Czar, who ordered him given a present of 25 roubles and the above promotion. At the end of his two-years' service in Russia he returned to Philadelphia with \$5000 in cash, and within ten days started for Iowa, where he first settled in what is now North Liberty; and in 1858 removed to Laporte City, Blackhawk Co., his present home. Here he practiced his profession, gradually becoming interested in farming, bee-keeping, fine-stock raising, and banking, in all of which he has been peculiarly successful.

About a dozen years ago he concluded to try the South, and, as a result, has spent his winters ever since at Daytona, Fla., becoming interested in the town financially. On account of ill health Dr. Oren has, within the last four or five years, retired from all active business except such as is necessary in looking after his financial interests in the bank and elsewhere. When I visited him at his home about 15 years ago he was living on his 1200-acre farm, fully stocked with Clydesdale horses and shorthorn cattle, his specialties, and an apiary of about 300 colonies. The farm and stock were cared for by hired labor; but the apiary work was all done by himself, wife, and two daughters.

He first became interested in bees in 1858, starting with six colonies which cost him \$108. In 1860 he bought from Mr. Mahan the first Italian queen that ever crossed the Mississippi River, for \$22.50. In 1861 his apiary numbered 150 colonies, and has varied from 100 to nearly 300 from then until he retired from active work a short time ago.

His specialty was comb honey, and his success in both honey production and wintering was phenomenal, excelling in both these

respects any other bee-keeper I was personally acquainted with in Iowa. Many of his methods, both in bee-keeping and stock-raising, were original, and differed widely from any I have seen practiced by any one else, and they were peculiarly successful. His bees earned him much of the money invested in other lines, and in this respect he divides honors with Adam Grimm, and not second honors either.

As a friend I have found him to be such a few men have the power and disposition to be. He in his daily life fully lives up to his ideal. He once said to me in words, "What is the use of a man living in this world if he can't be helping somebody?" His success in this line has been equal to his business success.

Pioneers of improved American bee culture yet alive who antedate Dr. Oren's commencement of the business can probably be counted on the fingers of one hand; and I doubt whether any of them have had as unique, interesting, and successful all-round personal history as he has.

Dr. Oren has been president of the Iowa State Bee-keepers' Society.

Stuart, Fla., Aug. 10.

#### HOUSE-APIARY AT NOTRE DAME, IND.

Wintering in a Warm Room; some Interesting Observations.

BY JOHN CHRYSOSTOM.

One of the house-apiaries on the grounds of the University of Notre Dame is a frame building, in length about 60 feet, in width about 9, in height about 10 from the floor to the cone of the roof. It is built of matched lumber throughout, being so tightly jointed that mice and such small animals can not get into it. A small platform on the floor, running the length of the building, is about 3 feet wide and 3 inches high, sloping to the front about an inch, so that the moisture which may collect at any time in the hive will readily run out. On this platform are small frames about 2½ inches apart, inserted in the wall, the exact size of the porticos of the hives, against which the portico of the hive fits tightly, forming another portico about 8 inches high, 12 inches wide, and 11 inches deep, thus making a secure place for the bees to sleep warm at night, especially when there is a large quantity of brood and young bees in the hive, which would make it very uncomfortable for the field bees.

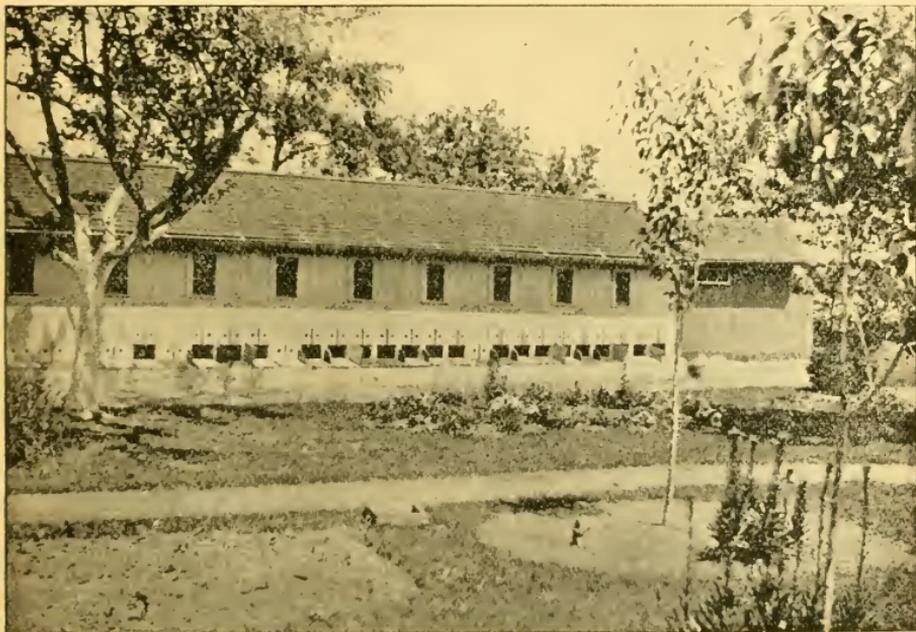

All these openings and hives are on one side — the southeast side of the building — as are also the windows, which are swung on hinges as a matter of convenience. The porticos have tight-fitting slides with ventilators, and may be closed and opened at will. This is very convenient on cold bright windy days in spring, or when bees are robbing, or when looking through a hive in early spring or late in the fall, when the slide and all the windows can be closed, in which case there is no trouble from robber bees.

But, how about the noise, and walking on the floor so near the hive? Bees become accustomed to it, and do not mind it.

I never saw a house-apiary, and know not how they are generally built, or what advantages others may find in them; but for me I find it most convenient and satisfactory. I would not keep bees if I had to winter them in cellars and caves. The hives in this house are only about 2½ inches apart, and it is very easy to pack them in chaff or straw if it is ever necessary. My opinion is this, founded on experience: That it would be better to have the house facing east, with plenty of windows on the east and west sides; also have a large window in the south end, the north and south ends being flanked with good windbreaks.

sun till noon, and on bright days in spring the top of the hive becomes very warm, even on cold days. Besides this source of heat, there is a coil of steam-heating pipes running along the wall under the window, and the temperature of my room is seldom as low as 50 deg., either night or day. In the afternoon it is up to 75 degrees. The bees get their fresh air from under the window-sash. The hive is so warm and comfortable, especially when the north wind blows, that the bees take exercise in the hive, which oftentimes has been a great source of pleasure to me on winter days, watching them through the glass, as the side of the hive next to my writing-table is glass.

Oftentimes in early spring I have seen the bees fly from less comfortable hives when not

HOUSE-APIARY ON THE GROUNDS OF THE UNIVERSITY, AT NOTRE DAME, IND.

The advantages of this arrangement are that, on windy days, the bees would find a calm atmosphere as soon as they would drop down to the hives, and in early spring the sun shining through the windows and on the roof would raise the temperature in the building, and consequently in the hives, which I think would have a tendency to induce early brood-raising.

But, would not this be an inducement to the bees to fly out on cold bright days? I believe not, when their quarters are comfortable; at least, this has been my experience. I have kept a sixteen-frame colony on the window-sill in my room for the past three years. The window is situated in a southeast angle of the building, affording light and heat from the

a bee was to be seen from this particular one. As for funerals and house-cleaning in the spring, this hive is almost exempt. Perhaps not over 200 dead bees could be found in and about this hive the entire winter and spring.

I have seen them work about 6000 flights an hour on first honey or pollen. At night they appear to enjoy the lamplight, which is sometimes very close to their window. But, the noise? Well, they are aroused by the ringing of a large hand-bell every morning at five o'clock, and every hour till nine in the evening, besides vocal and instrumental music three times a day, when a class of fifteen or eighteen young men join in a chorus, which makes quite a racket. Nevertheless, these little creatures continue from day to day their

daily work as though they were in the tree-tops in some far-off forest.

[I would somewhat question the wisdom of having too much glass for the purpose of letting the direct rays of the sun shine directly into the house-apiary building. I should fear that, on cold days, when the sun did not shine, the building might be cold; for glass does not begin to afford the protection that some non-conducting substance like wood does. Perhaps the low temperature of one day without sun might be followed by a calm day with plenty of sun. Then the inside of the building would be very comfortably warm, if not hot, and that would possibly make a difference of fifty degrees in temperature. Mr.

the warm air and to the noises and all other unusual conditions. We have known of other instances of colonies being kept in a living-room, having an entrance connected with outdoors; but, so far as I can remember, these colonies did not fare very well. Perhaps there are some among our readers who have conducted similar experiments who will let us know about it.—ED.]

THE "A B C BOOK" HOUSE-APIARY IMPROVED.

BY JACOB MEISSNER.

I noticed in GLEANINGS that you are going to build a house-apiary to keep thieves out. I

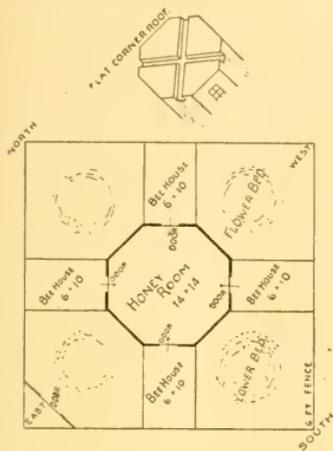

MEISSNER'S IMPROVED HOUSE-APIARY.

Salisbury and a few others who are using house-apiaries are, I think, wintering quite successfully without any windows save small glass lights that are closed up by shades.

Your experiment with a colony of bees in a living-room is quite interesting. One would think the warm temperature would excite them too much, and cause them to fly; but very likely they have become accustomed to

send you a sketch of mine. This house does not have to be built at one time. Indeed, I have not finished mine yet. The four small houses, or wings, can be moved anywhere. The central part is of eight pieces—four high ones, and four to fit the top of the roofs of the small houses. The whole structure is bolted together. The flat roof shown in the diagram is best for a movable house. To get into this

building, thieves must go through three locks. The whole building holds 96 colonies. Sheenwater, N. Y., Aug. 9, 1897.

GROUND PLAN.

[From an architectural point of view your house-apiary is very pretty; but from a pocketbook point of view I am afraid it would be out of the reach of the majority of bee-keepers. The present price of honey renders it absolutely necessary, if the bees are to pay all expenses and give a profit besides, that a house-apiary should be built as economically as possible. Mr. F. A. Salisbury has a building about 12 x 60, gable roof, which will hold as many colonies as yours, and which probably cost less than a fourth as much. Still, there may be some located in the cities who are not so much after the profit as they are for the pleasure of bee-keeping. To such a one the house-apiary above will commend itself.—ED.]

## BEE-KEEPING IN BANANA LAND.

### Some Interesting Facts About the Flora.

BY H. G. BURNET.

There is no tract of land in the world, of the same size, that I know of, that has as diversified a climate and soil as this island of Jamaica. This diversity is very pronounced, so that, in a journey of a few miles, one can pass from arid plains to where there is a rainfall of sufficient amount to keep vegetation in luxuriant growth the year through. These conditions are brought about by the peculiar topography of the island, in combination with the northeast trade-winds. The range of high mountains through the center of the island causes most of the rain to fall on the north and central portions, while on the south side there are districts where the rainfall does not exceed ten or twenty inches, and on the mountain-tops and north side it is from 80 to 150 inches a year.

On the dry Liguanea plains on the south

sides there is a very interesting honey flora, the most noted being a variety of acacia, locally known as "cashaw," that blooms twice a year—in May, and again in August and September, and that grows luxuriantly all over the dry plains. The honey from this source is thick and white, and of very fine flavor, much like white-clover honey. Then there is the lignum vite, logwood, and quite a long list of trees, plants, and vines that yield more or less honey; and, when seasons are favorable, very large yields are obtained—so large, in fact, that it is almost impossible to overstock the range, and large apiaries pay well.

In the dry districts the flows are very distinct, and great skill is needed to keep bees strong at the proper time to catch the full benefit of the yield; for often for weeks bees will get nothing; then the cashaw or logwood blooms suddenly open, and fairly drips with nectar; and the careless bee-keeper will lose nearly all of it while the bees are raising a force strong enough to gather the abundant harvest. So it is often the case that he goes to work and extracts too closely, and his bees starve or abscond, or "the moth" plays havoc, and "bee-keeping doesn't pay." But there are some wide-awake apiarists who have the best modern appliances, and are quietly increasing the number of colonies, and starting out-apiaries, and who will surely reap a well-deserved harvest. In the district about Spanish Town there is complaint that the hundreds of acres being cleared up and planted to bananas—under irrigation—is reducing the flows very materially; but there are large areas still untouched. Coconut palms also yield honey, as do nearly all of the palm family.

Leaving the plains, and getting up into the hills, we find a more varied flora; for the rainfall is greater, and, with decent care, bees will never need feeding, as they often do on the dry plains, for there are nectar-yielding plants in bloom all the year round. Logwood, which is found sparingly on the dry plains, here grows with great luxuriance, and is found in nearly all the pastures on the great cattle-ranches—here called "pens"—which abound throughout the island.

About Christmas, bees get more or less honey from a convolvulus-like bloom called "Christmas pop," that stimulates brood-rearing, which is of great value, as it puts the bees in good shape, if properly managed, for the harvest from logwood in January and February, which lasts from four to eight weeks. Oranges abound in many parts of the island, and, where plentiful, give considerable honey, following closely after the logwood.

The list of nectar-yielding plants in the hills is quite a large one, including many large trees as well as small weeds and vines. A good many swarms have escaped to the rocks and many caves that are found throughout the hill country. With the facilities of good roads—none better anywhere—and convenient railway transportation, it is a wonder some of the apiarists on the plains have not moved their bees into the hill country after

the cashaw flow has stopped. J. S. Morales, the enterprising secretary of the Jamaica Apicultural Society of Spanish Town, not only handles Root's goods, but rides a bicycle to his out-apiary, and is much in request by a number of beginners in various parts of the island. Friend Morales finds a wheel invaluable in his business, as does the writer; for with the magnificent roads everywhere through the island "it's just fun" to wheel through the lovely and varied tropical scenery.

I again invite A. I. R. to visit this island next winter. He will find many things that will interest him as much as any thing he has seen on any of his travels—immense fields of bananas grown under irrigation; great waterfalls, wonderful medicinal springs, large sugar-plantations, truck-growing under irrigation, great caves, etc., as well as a wealth of tropical vegetation that will be a revelation to him. He can bring his wheel, and ride everywhere, and he will find that he has many friends here as everywhere.

Linstead, Jamaica, Aug. 30.

[Thanks. Will try to send him down one of these winters when it is cold and bleak here, and lovely with you.—Ed.]

#### SMOKER FUEL.

Some New and Valuable Kinks in Handling Bees.

BY N. E. BOOMHOWER.

About every apiarist has his own whims and ideas; and among them are some who would rather use a thing of their own originating than to use one they knew was better, but decline simply because some one else got it up, and say it is "no good."

I will give a few points that perhaps will do some one some good if he will try it. One of them is, *fuel for the smoker*. We use old phosphate-sacks that have been laid out in the rain, and washed out, or burlap of the same nature, which can be had in almost any quantities at the junk-shops for one-fourth cent a pound. This fuel has been used by a good many, but perhaps not in the same shape we use it. We take a phosphate-sack and roll it up lengthwise as tight as we can handily with the hands; then we take common cotton twine and tie around the rolls about five inches apart, or about the right length to fit in the smoker; then chop up the rolls between the strings with an ax, and so have a very handy piece of fuel that will just fit into the smoker. One bundle will last two or three hours, and make a much nicer smoke than any wood I ever used.

We take sacks and fill them with the bundles, and send one to each apiary, and that will last through the season. The advantage of this fuel is that there are no sparks; and those who have chaff hives will know that this is one good point. Only a short time ago I burned up four chaff hives on account of using wood for fuel. Your smoker is always cool, easily lighted, and I have known a smoker to stay lighted three hours without

being touched. In lighting the smoker, take the burnt fuel that was used the last time; and by touching it with a lighted match it will burn like charcoal, thereby saving the time of cutting shavings. The cost is about five cents per hundred colonies per season, and about fifteen minutes' work to prepare it.

W. L. Coggshall, I think, was the first to use fuel in this shape, and you could get him to use no other.

Another useful point is in putting a hook on the smoker—one stamped out of band iron, about  $\frac{7}{8}$  inch wide and 3 inches long, with one end made sharp, and bent like a fish-hook, so it can be screwed on about the center part of the back of the bellows, and about two inches from the top, where it does not interfere with the hand. This will be found very handy, as, instead of groping around and bending over, or reaching to find a level place where the smoker will stand, you can hang it on the edge of the hive, and be out of your way, and save a good deal of time and annoyance.

Another point we just caught on this season is in driving the bees down in the supers, either in extracting or comb-honey supers, where bee-escapes are not used. This is done by taking hold of one corner of the oilcloth and pulling it loose, just so the opposite corner hangs; and, by blowing smoke from the smoker by the side of the cloth, and flapping the oilcloth up and down quite rapidly, you will be surprised to see how quickly the little fellows will leave and go downstairs. It seems to draw just the amount of smoke required, and it scatters it evenly over the frames, and forces it down in between the combs farther than a smoker will do it, and not so much, and does not get the bees excited. With a little practice a person can nearly clean the supers of bees; and where you extract you hardly need to brush the combs.

West Groton, N. Y.

[Mr. N. E. Boomhower is a son of Frank Boomhower, of Gallupville, N. Y. As I saw Mr. N. E., or Novice, as he is familiarly called, working in one of Mr. Coggshall's apiaries, I can testify to the correctness of every point he makes. It is indeed true that this old gunny-sack smoker-fuel is cheap and lasting, and it gives a good volume of smoke without sparks. I think Mr. C. told me he bought for this purpose old phosphate-sacks. The smell of the phosphate would do no harm, but, on the contrary, would have a more favorable effect on the bees. I do not suppose it would pay ordinarily to buy new burlap for the purpose of making smoker fuel, and yet it might.]

The idea of flapping smoke into extracting-supers for the purpose of expelling bees by means of the enamel cloth or quilt is a valuable one. The principle seems to be in causing a partial vacuum in the super. A continuous stream of smoke is poured over the frames. The flapping of the enamel cloth, as explained, causes a suction, driving the smoke further into the super than it can be done with the smoker itself, strange to say. You have probably noticed this, that, while in bed,

if the bed-clothes are held fast at one end, and raised up suddenly, it will cause a suction. In the case of the hive the smoke seems to be driven into, or rather sucked into, the super, not by the *downward* flap, but by the sudden uplift of the cloth.

Well, how about the results? I saw young Boonhower drive bees out of super after super; and when he took the combs out to shake or brush, in many cases there was hardly a bee on the combs, so thoroughly did it do its work. I shall have more to say about this when I come to tell about my visit at Mr. Coggshall's; but in the meantime, brethren, try it and see how it works. If you use a flat cover, and no enamel cloths, try the ordinary robber-cloth that Dr. Miller recommended, but have it wet. As soon as the cover is removed, lay this on the frames, then try the flap act, and notice what it will do. Now try to smoke the bees down in the ordinary way with the smoker, in another hive, and I think you will notice the difference as I did at Mr. Coggshall's. Of course, you know Mr. C. does not use a bee-escape. His reasons for not using one I will explain at another time. —ED.]

#### DOES PURE HONEY CONTAIN ANY CANE SUGAR?

If Not, Can Even a Small Per Cent of it be Detected by Analysis? Chemical Terms.

[Some little time ago I stated editorially that I was under the impression that pure honey was liable to contain a small per cent of cane sugar, and that, when the chemist detected a small amount of it in honey, it should not be construed as evidence that the honey had been adulterated. On page 493, Mr. Selser, of Philadelphia, a chemist, criticised the statement, adding that my mistake doubtless occurred from the fact that I had confounded chemical and commercial terms. "Pure honey," said he, "does not contain any cane sugar, commercially speaking; . . . but there is a very large percentage of sucrose, and sucrose is a chemical term for cane sugar."

Prof. Cook, on page 624, in referring to this article of Mr. Selser's, said he thought it contained several errors, and hoped it might be submitted to Dr. Wiley for review. Following up the matter I wrote to the doctor, sending him a marked copy of the article in question, and the following is his reply:—ED.]

U. S. DEPARTMENT OF AGRICULTURE,  
DIVISION OF CHEMISTRY,  
WASHINGTON, D. C., Aug. 30, 1897.

*The A. I. Root Co., Medina, Ohio:*

Gentlemen:—I take pleasure in complying with your request of the 21st instant, in respect to the statements in the article on page 493 of GLEANINGS.

The subject under discussion is hardly a matter for argument, because it is simply a question of the use of terms. The expression "cane sugar" is used constantly by chemists as a synonym for sucrose, although I do not believe that sucrose is used synonymously with cane sugar by the commercial world. In commerce, cane sugar is simply sugar made from sugar cane, as beet sugar is sugar made from beets, and maple sugar, sugar made from the maple. Chemically these sugars are all identical, and are spoken of indiscriminately by chemists as cane sugar or sucrose.

The sugars which are present in a genuine honey are almost exclusively cane sugar, or

sucrose, and invert sugar, which is made by the inversion of cane sugar. It is probably true that the original sugar of nectar is almost exclusively cane sugar, which is inverted either by the acid juices of the plant itself or by the digestive organism of the bee. In ordinary honey, this inversion is almost completed, and very little cane sugar or sucrose remains, almost the whole of the sugar being invert sugar that is composed of about equal portions of dextrose and levulose.

It does not appear to me that the criticism of your correspondent, Mr. Selser, is well founded; but the character of his statements does not quite corroborate his claim of being a graduate of a special course in analytical chemistry. It is not quite in harmony with a scientific spirit to state that "there is not one per cent of cane or common sugar in pure honey. In this statement I defy contradiction."

I do not claim to be a honey specialist, and it is so long since I graduated in chemistry that it has ceased to be a matter of gratification to me to remember the date. I have, however, never been so certain of any position that I may have taken in scientific matters as to boldly proclaim that I defied contradiction. In point of fact, the sugars which are present in honey are exactly the same as the sugars of commerce; viz., sucrose, or cane sugar; dextrose, or right-hand sugar; and levulose, or left-hand sugar. It would require a great many statements from Mr. Selser to alter this fact, but still it may be easily contradicted.

Respectfully,

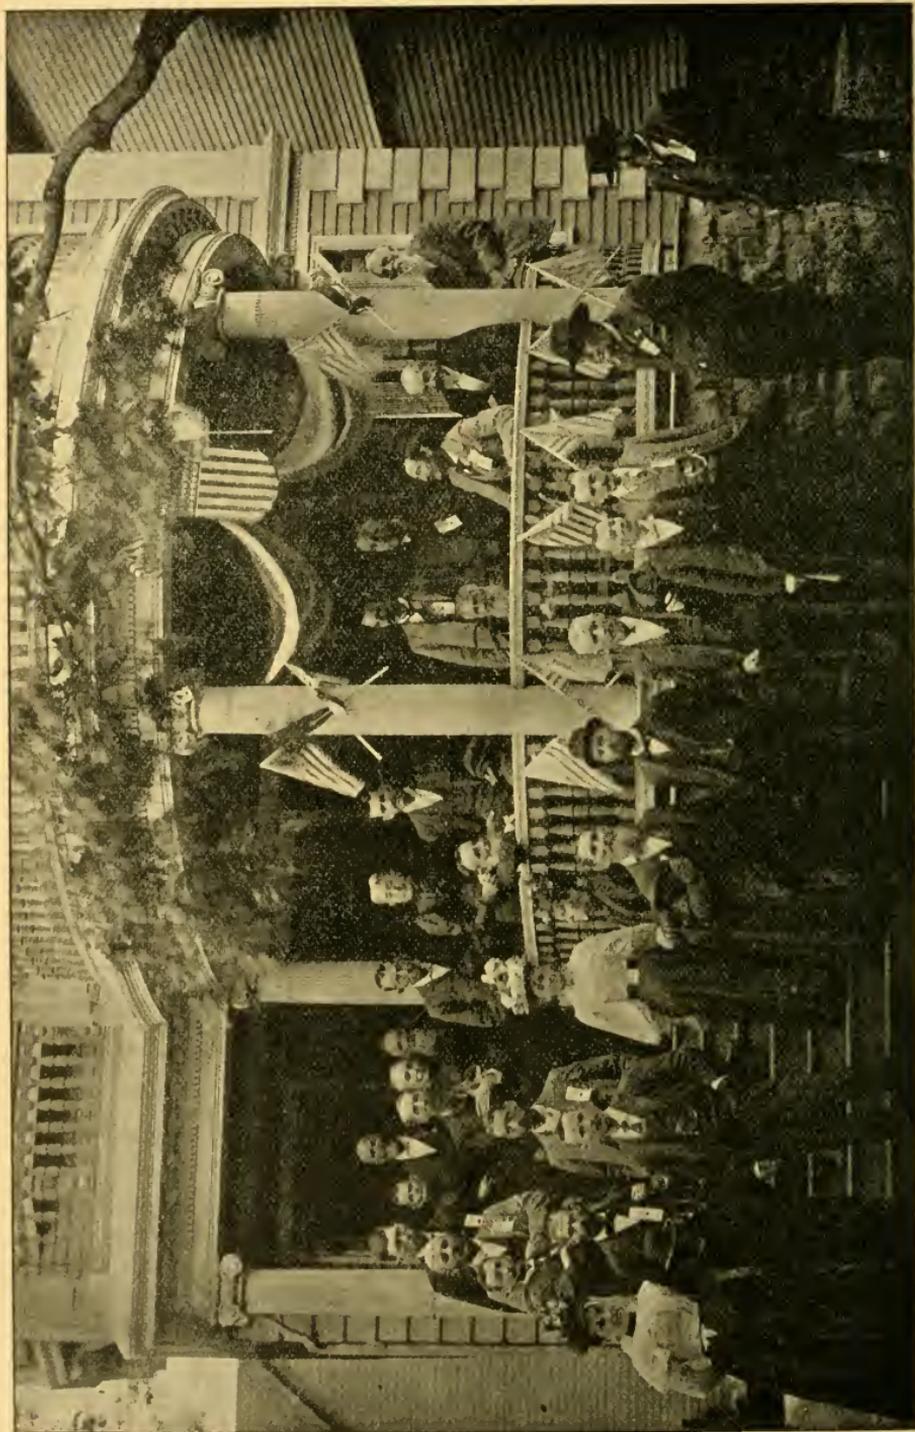

H. W. WILEY,  
Chief of Division.

[After receiving the foregoing I sent it to Mr. Selser for further review, and he replies as follows:—ED.]

The article you first published, the basis of which was taken from "Prof. Wiley's Book on Honey Adulterations," as well as the present article from Prof. Wiley, is not a matter for discussion between the two classes—scientist and laity—and as such is very misleading. I do not contradict a word of Prof. Wiley's paper; from a scientific standpoint it is *absolutely correct*, and I desire to state that my words defying contradiction were addressed to the reader of GLEANINGS—the honey-producer. I desired to make it very emphatic, that, if he placed one to five per cent of commercial sugar in the honey, it could be detected by analysis; and your statement that "five per cent of commercial sugar in honey did not prove that it was adulterated" I felt was an error that might result in terrible consequences. In proof of what I say, I make the following offer to the readers of GLEANINGS:

Mail me five samples, say 3 ounces each, of honey; let four of them be pure, and one adulterated with five per cent of commercial sugar; number each one. If I do not detect the one that is adulterated I will pay to the sender \$10.00; if I do detect the five per cent of commercial sugar, he is to pay me \$5.00, or the price of my analysis, \$1.00 a sample.

Now, scientifically, turn to the "Government Book on Adulteration of Honey," 1892, page 791, the top of page showing sample No.

SOME OF THE PROMINENT DELEGATES WHO ATTENDED THE BUFFALO CONVENTION—SEE ILLUSTRATION.

41 of pure honey to contain 8 per cent of sucrose and 65 per cent of reducing sugar. This sample was proven to be positively pure. Now, Prof. Wiley uses the same word for sucrose as cane sugar, and also says the words are not used synonymously in the commercial world. Here is where the line must be drawn, and I repeat the professor's words: "It is simply a question of terms."

Now practically. In my visit to a large honey-producer I mentioned the fact that my State, Pennsylvania, had a law that, if the smallest per cent of commercial sugar was detected in honey, there was a fine of \$50.00 for every store selling it. He said that, in the fall, he fed a lot of granulated sugar. Most of it had been consumed by the bees, and but a very small per cent remained in the combs. When fruit-bloom commenced he thought it so small that he paid no attention to it, and extracted it with the other frames in the first extracting. This man is a good man, and I am sure he meant to do no harm, as he had seen the statement that all pure honey contained a small per cent of cane sugar.

Had any party from Pennsylvania bought his honey and put it in bottles, marking it "Pure," and sold it to twenty stores, it would have cost the bottler \$1000, and ruined him for life. Will not Prof. Wiley pardon my strong words in the light of these facts?

Philadelphia, Pa.

W. A. SELSER.

[I am glad to note that there is no real disagreement between Mr. Selser and Dr. Wiley; and I am glad to note, also, that Mr. S. is perfectly ready to prove his faith by his works; so, then, let the samples go in to him. We will gladly give place to the results in these columns. Send him not only sugared samples but glucosed samples; and when he sends you the report, mail a copy of it to us, together with a statement of just how the honey was originally "doctored."—ED.]

### THE DEEP-CELL FOUNDATION.

Conditions Under Which Bees Build Heavier Comb.

BY F. A. SNELL.

I have eagerly read every thing that has appeared in GLEANINGS on the above subject, inasmuch as I think it a very important one. If it proves what is hoped, it will have an important bearing on bee-keeping in the future, so it seems to me. The importance of partially drawn combs, especially in the central sections of each super put on at the opening of the honey harvest, is a conceded fact with most bee-keepers. The drawn foundation will, if in no other way objectionable, come into general use in the sections. I think shallower cells may be preferred by many after the first super for each colony at the opening of the harvest. The reports given of trials made near the close of the honey-flow or during a light flow, of heavy combs, or those having more wax than some natural combs have, could hardly have been expected to be otherwise. Every close-observing bee-keeper has

noticed, no doubt, that at different times the thickness of combs varies much, depending wholly, so far as I have observed for thirty years, upon the honey-flow at the time the comb is built. You mention this fact; and you will remember that I in a former article took considerable space in calling the attention of apiarists to the matter of thickness of combs, stating when the conditions and honey-flow were right for the building of very light combs, and the reverse.

My experience with the deep-cell foundation is very limited. I received a sample last spring; and when the bees were well at storing surplus I put it in a section and placed it next the glass side of the super. I watched the bees closely. Work was commenced on it at once, and the cells drawn out and finished. The weight of the comb is all that I could ask for, and this one test impressed me very favorably. Next season I hope to give it quite a thorough trial, and I hope all who have done so this season may give their experience through our journals. Even if the new foundation be discarded in a few years, the effort will not have been in vain. Much useful knowledge will have been gained. I think it has come to stay, and prove of value to the bee-keeping fraternity.

Milledgeville, Ill.

### DRAWN COMBS AND DRAWN FOUNDATION.

*Friend Root:*—Referring to my article on page 560, August 1, regarding drawn combs, I was not as clear as I should have been; I therefore explain that the drawn combs I used, and which did not give this season as good satisfaction as full sheets of foundation, were leveled down by breaking the cells, in all cases where they were over  $\frac{1}{4}$  inch in depth; possibly some were left deeper than that. What I said would not reflect on the new drawn foundation, which, I believe, will do all that is claimed for it, and the finished product will be first class in every respect. This I hope to demonstrate next year by actual experience. But unfinished sections at the close of the season are like many other things. We shall have them whether we like them or not.

H. LATHROP.

Browntown, Wis., Aug. 14.

### BEES ACCEPTED IT AT ONCE.

I consider your drawn foundation a marvel of workmanship. Bees accepted it at once. I have not yet sampled the honey, but I have no doubt it will be as tender as natural comb, if not superior to it.

C. S. HARRIS.

Holly Hill, Fla., Aug. 30.

### THE NEW DEEP-CELL FOUNDATION AHEAD.

I have tested the drawn foundation you sent me this summer as follows: I put the pieces, which were in size 2x4, one in each section, which made them half full, and put them together in one corner of the surplus-box. As the bees usually begin to fill the sections in the center of the surplus-box, they accepted your drawn foundation at once, and

extended the comb down to the bottom of the section, and built or stuck it all around, the same as any other foundation. For my part I should prefer the sections only half full of the raised foundation, as I think it is just as good as having them filled, thereby saving expense. The principal feature of it is to get bees started to build; after that, there will be no trouble, and your new process of manufactured comb starts them *sure*. The only difficult part I experience is in fastening them to the section.

Bloomdale, O., Sept. 7. M. N. SIMON.

#### THE DEEP-CELL FOUNDATION A SUCCESS IN EVERY WAY.

The 20 combs of drawn foundation were all finished up nicely, and their eating qualities can not be surpassed. This was a very poor season to test it by the side of common foundation, as bees would start on any sheet of wax. Some years we know it is hard to start them, even on the best foundation. I expect to use the drawn foundation another season entirely.

J. C. WHEELER.

Plano, Ill.

#### UNFAVORABLE FOR NEW DRAWN FOUNDATION.

The willow-herb was a failure in this locality, so I could not give the new drawn foundation a test from that source. A few sections containing common foundation have been filled and finished from fall flowers, but none containing new drawn foundation have been finished. The third day after putting on the supers the common foundation was drawn out farther than the new drawn foundation clear down to the base.

R. E. ASHCRAFT.

Woodville, Mich., Sept. 3.

[It is the exact truth that we want. If there are more reports of a like character, let them come in.—ED.]

#### OCCURRING THOUGHTS.

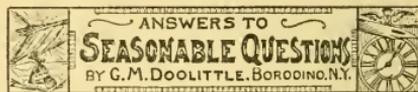

BY J. W. SOUTHWOOD.

*Mr. Editor:*—On page 527 you say, "It does little if any good to put any thing on a bee-sting." Try *ma-le-na*. It not only allays the pain if applied soon, but by its pleasant smell destroys the odor of the sting and thus prevents the bees from becoming angered. It is found in drugstores generally, and costs 10 cts. per box. It is a good salve for many purposes. It is manufactured at Warrior's Mark, Pa. [The pain is very brief at most, and my way is to grin and bear it. The pain would be over before I could get the stuff on. To destroy the odor I blow smoke on the wound.—ED.]

On page 533 of *American Bee Journal*, Mr. A. B. Mellen says he prefers piling up the supers five or six high with a cone escape on top, rather than use a Porter bee-escape, as it saves one handling. I have never practiced that method, but have seen it practiced, and believe I can free the supers with less work and less liability of destroying the capping by the use of the Porter escape. I think it a grand invention.

One difference between *pure* blood and thoroughbred is that pure blood is barely susceptible of improvement, while thoroughbred can be greatly improved. G. M. Doolittle, on pages 500 and 501, points out this fact relative to the black bees as compared with the Italians. While the latter have been, and may yet be, greatly improved, the black or Germans are barely susceptible of improvement.

When from some cause queens are not clipped, many times the queen may be caged as she issues from the hive. Prepare a roomy cage; and if the hive has a full entrance, prepare an entrance-block; and, if near at hand, pass to the hive while the swarm is issuing, and lessen the size of entrance by moving the entrance-block endwise at one side of entrance so the eye can easily see the full width; and as the queen comes out cage her by putting a cage over her. She usually comes out quite reluctantly toward the last, and sometimes comes only to the entrance, and then goes back. In such cases I open the hive and take her out, as she is quite easily found. I frequently take queens of after-swarms in this way.

#### ITALIANS VS. BLACKS FOR WINTERING; FEEDING; UNIFORMITY IN HIVES; WIRING FRAMES; METAL-CORNERED FRAMES.

A correspondent sends in a number of questions; and as I do not think it best to take as much space in answering them as I usually do to each question, I have thought best to number them and answer by number.

1. Do you think that Italian bees stand the cold winters we have in 43° north latitude as well as the black or German bees?

*Ans.*—It is said by some that they do not; and I used to believe that what the "some" said was the truth; but that was before I made any careful tests in the matter. Some eighteen or twenty years ago I began to look carefully into the matter of wintering; and during the experience of all of these years since, I have become convinced that there is little if any difference in favor of either along this line. Some winters the blacks seem to do the better; in others, the Italians come out ahead.

2. A neighbor has given me some bees in box hives, because he thinks they have not stores enough to winter on. How can I feed these bees?

*Ans.*—This is very easily done at this time of the year by boring a hole in the top of the hive, if there is none already there, and placing a feeder on top, covering all with a hood, box, half-bushel, or something of the kind. If you do not have a feeder, a suitable-sized tin basin or pan will answer every purpose for such feeding. After having the feed in the pan,

pull up some rather short grass and scatter it over the top of the feed for a float, to keep the bees from drowning, and set up a piece of section in such a way that the bees can climb on it over to the feed. Be sure that all cracks under and about your cover are bee-tight, otherwise you may have a bad time with robbers.

3. Can I not put off feeding till winter just as well?

*Ans.*—No! a thousand times no! When will people learn not to put off the feeding of bees till cold weather comes? October 1st to 10th is quite late enough to feed bees; but should it so happen, from sickness or otherwise, that the bees are destitute of food when winter sets in, take the box hives to the cellar, turn them bottom side up, and every day or two sprinkle a few tablespoonfuls of honey over the bees and combs, having the honey a little more than blood-warm. If they are a large colony, or seem to require more, use as much as a half-teacupful each time. In this way bees have been wintered successfully; but the chances are that a loss of feed and bees will be the result.

4. Would it do to leave them till winter, and then set them in a warm room under netting, to feed?

*Ans.*—No, I should not like to try that. From my experience in the past, such a procedure would cause them to become uneasy and to go to breeding, thus consuming large quantities of food, which would in all probability cause diarrhea, resulting in death. There is a chance for such occurring where fed in the cellar, but not as much as in the warm room.

5. Could these bees be wintered in a warm room?

*Ans.*—The chance for this would be very slight indeed, although such has been tried with success in a few instances, I believe. The cellar is a much better place, and requires much less labor and care, hence I see no reason for desiring to try such risky experiments. [See page 697.—ED.]

6. I am about to make some new hives. Is there any advantage in both upper and lower story being just alike, so they can be used together or separately? If so, how would you arrange the entrance?

*Ans.*—There are many advantages in having all hives in use of the same size, and several in having both stories just alike. In making, you can get along with much less bother; you can use the upper story for the same purpose you do the lower, at any time you so desire, which will be quite often; and one, two, three, or more will fit together like clock-work in tiering up, without any outside shell to cover them. By making the entrance in the bottom-board where it should always be, this part need not affect the hive at all. If made right, you can enlarge or contract the same by simply moving the hive a little backward and forward on the bottom-board, thus saving any entrance-blocks.

7. Would you advise me to buy wired frames by the hundred, filled with foundation?

*Ans.*—That depends upon conditions. If you are to work your apiary for extracted

honey it might be the better plan; and if you work it for comb honey, and have not the time to look after the combs properly when being built; or if your time is very valuable, it may be the better way. But with the average bee-keeper I think it will pay fully as well, especially where the sections are filled with thin foundation, to use only starters of comb or comb foundation in the brood-frames, say from  $\frac{3}{4}$  of an inch to an inch wide, as it will to fill the frames full of the same, to say nothing about the saving of money and time. It is the opinion of several of the best bee-keepers of to-day, that as much or more comb honey can be secured by allowing the bees to build their combs in the brood-frames, using starters as above, than by any other mode of procedure. Certainly comb honey of the most fancy make can be produced in this way, and the difference in selling price between this and that built by a colony having old black combs below, where much of the old wax gets into the capping of the section honey, is an item worth looking after, but one which has no bearing on the foundation question, however.

8. A neighbor of mine is using metal-cornered frames. Are they enough better than all-wood frames to pay the difference in price and the extra trouble of making?

*Ans.*—I tried the metal-cornered frames several years ago, and did not like them well enough to use any more of them. The trouble I found with them was that, in carrying the hive from one place to another, they would move about so, even after the combs were built, that the frames would require respacing after every time moving, else a lot of bad combs was the result. Then in handling, the corners would get bent unless care was used, so they would not hang true in the hive; and sometimes the fingers would get cut. I wonder if the Roots use them now. [A I. R. used to like them (perhaps he does now), but there are none in use in our apiary now; in fact, we do not even offer them for sale. They were displaced in our apiary by self-spacing frames, which we prefer.—ED.]

PREDICTING THE HONEY-CROP PREMATURELY.

*Mr. Editor.*—I've come to the conclusion that I do not want to report the honey crop. It is usually much spotted; that is, there may be a good flow of honey in this locality, and only a few miles distant a failure. If I report a good crop, it lowers the price. If I report a failure, only a short distance away there may be a good crop. Those who have honey to sell, seeing my report of a failure, ship in here, injuring the market for those who live near.

When there is a good flow for a day or two,

some producers write to the periodicals, "Tremendous honey-flow!" and before it reaches its destination, bees may not be making a living. This year a man came for sections, saying that he never saw honey coming so fast. We ordered them for him, and they remained here one month, and I doubt if he ever opened them.

Some newspapers report a big yield of corn, which is far from the truth. It didn't ear well, neither did tomatoes set. The best crop in this locality was blackberries. It is reported that a man dug his potatoes, dropping them into a jug, and after working all day it was not full.

MRS. L. HARRISON.

Peoria, Ill.

[See editorial on this subject, page 670.—ED.]

#### DISCOURAGING FOR FLORIDA.

You may announce that the present season has given us not one pound of surplus honey in this "neck of the woods." This is the most signal failure we have ever known all along Florida's East Coast. As I have given you some fine records from here I will not shrink from recording this surprising failure. Except for the killing of the mangrove in '95, I do not see how we could have had a season like the present. By next season we shall get honey from that source again.

Hawks Park, Fla., Aug. 27. W. S. HART.

#### THE BEAR AND THE BEES; THE FATE OF THE BEAR.

We never had any bee-hives kicked over by horses or sheep, but we had two kicked over last night by a bear, and the honey and brood eaten out of one. She was scared away three times, and came back the fourth time, all in five hours. I twice drove her away with two Winchester; the last time I put a hole through her jugular. This was my first chance at her. I was away when she came first, and my wife shot at her. Mrs. Bear was a dandy, and weighed 400 lbs. I shall take her hide to the tannery to-day, and will make a rug of it. She was killed at 11 P. M. After bleeding ten minutes she got up and came at me as I went to her with a light.

F. T. HALL.

Barron, Wis., Sept. 3.

#### A "SENSITIVE" HONEY-PLANT.

Bees are now working lively on smartweed, corn-top, goldenrod, and other plants, and another very pretty plant with yellow flowers that is quite sensitive to the touch. I do not know the name of it, but will inclose a sample. The leaves are always facing in the direction of the sun. Some have clusters of the flowers for ornaments in their dooryard.

Fairbury, Neb., Aug. 15. O. C. BURCH.

[The plant sent belongs to the family *Leguminosæ*, or pulse. This particular one is *Caesalpinia*, but a different species from *Poinciana*. The plant is nearly related to the well-known Mollie Heath honey-plant. It resembles the true sensitive plant of the florists, and it is closely related to the beautiful acacia of Cali-

fornia and Florida. These plants are so exceedingly handsome I would advise you to save the seed and offer it to bee-keepers. If it is hardy in Nebraska it will probably make a beautiful dooryard plant throughout the whole North. I should be glad of a small packet of seeds myself.—A. I. R.]

#### LIMITING THE QUEEN'S LAYING CAPACITY BY THE USE OF PERFORATED ZINC.

I notice in a late issue of your journal that you object to caging or taking out queens during a honey-flow, "as the bees sulk too much." I have not tried it, only as a colony happened to be queenless, or was made so in the operations of queen-rearing. I think you are correct, but it has occurred to me that that difficulty might be overcome by caging the queen on one comb in a cage made of perforated zinc, so that the bees could have full access to her and she could lay to a limited extent on the one comb only, while the rest of the brood-nest is being emptied of brood, and being refilled with surplus for extracting.

Estero, Fla., Sept. 3. J. S. SARGENT.

[The plan you speak of has been tried, and a few years ago it was thought it might be a big thing; but we scarcely hear of it now. One trouble was that, when the queen failed to raise the usual amount of brood, through no fault of her own, the bees proceeded to supersede her. In short, this contracting the queen's room induces a condition of discontent on the part of the bees, and of course they fail to do their best work.—ED.]

#### THE DANZY HIVE.

I have put one swarm of Italians into a Danzy hive. They have completely filled the brood-nest with absolutely straight combs, with only starters, and finished the super of 32 sections with the nicest white honey I have ever had, and all in exactly two weeks from the day I swarmed them. I like the mechanism of the Danzy. There was not a burr-comb to be seen when I took off the sections above noted, this week.

I suspect all will have beautiful clover comb this year; but those tall sections of thin beautiful clover honey are certainly enough to bring out a hearty interjection.

Indianapolis, Ind. T. C. POTTER.

#### WHITE CLOVER; GROWING AND GATHERING THE SEED, ETC.

Never seeing any thing in your publication about gathering white-clover seed, we make inquiry as to what method is used for cultivating and gathering it.

JOHN COLEMAN.

Altoona, Pa., Aug. 23.

[I shall have to confess that I have never heard of cultivating white clover. Of course, we sell the seed of the white Dutch clover, which is pretty much the same thing, and this, I believe, is generally sown the same as alsike or red clover; and my impression is the seed is harvested in much the same way, as it has a good deal shorter blossoms, and nearer the ground than the alsike. There may be,

however, some modification in the way of getting the seed crop. As there are several among our readers who have grown and sold us the seed of white Dutch clover, will they kindly answer the above?—A. I. R.]

#### BEEES HANGING OUT.

In GLEANINGS for July 15 I see on page 531 the question is asked, "What is the cause of bees hanging out?" I think the bees become damp for want of a little upward ventilation; and I find by putting a wedge under the cover at the rear end so as to give the bees a little air-current during the extremely hot weather, and taking out the wedge when the extreme heat is over, and letting the rear end of the cover down again, the bees work right along, and there is very little loafing. I use a wedge  $\frac{1}{4}$  inch thick. WM. H. EAGERTY.

Cuba, Kan., Aug. 6.

[Friend E., I think you are right about the bees; in fact, substantially the same treatment has been recommended in GLEANINGS, and found to be successful, if I am correct.—A. I. R.]

#### SWEET CLOVER.

I send you an old number of *Clover Leaf*. It contains an article on sweet clover, which struck me as being a very able one.

Sweet clover has gained a foothold along the Cuyahoga River in Independence, next township to Bedford west. We notice good results from an apiary that father has located there. I have saved and fed the fine hay, and the horses eat it with a relish. I believe it to be an excellent forage-plant.

Bedford, O., Sept. 15. EDSON HAINS.

[The article from *Clover Leaf* is certainly very full and instructive. We make a brief extract from it as follows:—ED.]

General S. D. Lee, President of the Mississippi Agricultural and Mechanical College, in a letter to this office, says: "What was the poorest part of my plantation six years ago is now the richest from the use of melilotus, and the hay is, in my judgment, the superior of red clover for stock."

#### SHEEP IN AN APIARY.

In the last number of GLEANINGS I read what you have to say about letting sheep run in the apiary to keep the grass down. But there is a surprise in store for you if you ever try the thing in your yard. The sheep will strip your Concord's of the last leaf first before they go at the grass, and they will climb on top of the hives in order to get at the last leaf.

CARL VOLLMER.

Abzarokee, Mont., Aug. 14.

[Very likely sheep wouldn't do in our yard, on account of the grapevines. There are no grapevines in Burt's yard.—ED.]

#### SUCCESS OF THE PETTIT SYSTEM.

The pleasure I find in keeping up to the last improvement caused me to try Mr. Pettit's comb-honey system. To have a fair trial I took 15 powerful colonies, which were divided into 3 parts. No. 1 had its hives raised with wedges  $\frac{7}{8}$  to 0; No. 2 received only a  $\frac{3}{8}$  block,

and No. 3 nothing, resting on the bottom-board. In each case I found all the outside surface of the two rows of sections next to the supers nicely finished; no difference could be noticed. Due attention has also been paid to the dividers. A part has received 5 cleats, another 3, and the third 2. These last turned out to be just as good as the first ones.

In conclusion, until better improvement is at hand I shall do away with wedges, and use dividers with only 2 cleats, one at each end.

FRANCOIS BENOTT.

Notre Dame des Neiges, Can.

#### FLIGHT OF BEES IN WINDY LOCATIONS.

I should be glad if you could get some practical bee-keepers, who have had experience in windy portions of the Pacific coast, to answer the following question, and let me know through GLEANINGS or otherwise: How far will bees fly in windy portions of the Pacific coast, and do well gathering surplus honey? Will they gather as much honey if they have to fly from two to four miles as they would if they had to fly only half of that distance?

Thebe, Cal., July 26. NICHOLAS SPARGO.

[Will some one on the windy coast please answer?—ED.]

#### SMALLER CROP IN YORK STATE.

My honey crop, as nearly as I can judge, will be about one-third less than last season; bees have not made much if any surplus since the first week in July. I give it as my opinion that this part of the State (owing to basswood not yielding honey) will be very much shorter than last season. I am selling in my home market at the same price as last year; viz., 10 to 13 cts. for comb per lb.

E. J. HAIGHT.

Rock Valley, N. Y., Aug. 5.

#### FAIR CROP IN IOWA.

A fair crop (not extra) of No. 1 white-clover honey. Basswood was nearly a total failure. Bees are gathering honey enough to keep up brood-rearing at present. Whether or not we are to have a fall flow of honey we are not advised, as we have not heard from our honey-prophet lately.

O. B. BARROWS.

Marshalltown, Ia., Aug. 4.

#### GOOD HONEY CROP IN UTAH.

A good honey crop was raised in this section, but no sales to date. I am doing very well selling to the local market in small packages. Reading those articles in GLEANINGS, on making home markets, has greatly interested and assisted me in this line. A. B. THOMAS.

Payson, Utah, Sept. 6.

#### RECIPE FOR HONEY APPLE-BUTTER.

One gallon good cooking apples; one quart honey; one quart honey vinegar; one heaping teaspoonful ground cinnamon. Cook several hours, stirring often to prevent burning. If the vinegar is very strong, use part water.

Loveland, Colo.

Mrs. R. C. AIKIN.

## "THE HONEY-BEE."

Dear Mr. Editor:—Some time since I presented a friend of mine with some honey. In response I received the inclosed verses. I take the liberty and pleasure of sending them to you for publication. I sincerely trust it will be your decision to publish them.

North Street, Mich. JAS. T. REID.

[With the greatest of pleasure. The lines are good—very good.—Ed.]

## THE HONEY-BEE.

By Rev. Volney M. SIMONS.  
The bee! She's in and out,  
And flits and flies about;  
She darts on rapid wings,  
And buzzes, bores, and sings  
Among the beds of flowers  
And in the beauteous bowers,  
In soft and sunny nooks,  
And by the purling brooks,  
In many a quiet spot  
By us o'erlooked, forgot—  
The honey-bee is there  
And here and everywhere,  
A making honey.

Unlike ourselves, unschooled,  
The bee is never fooled.  
She sucks the blooming rose,  
And well her instinct knows  
She'll get, by her own skill,  
Of the sweet rose her fill.  
The fragrant lily-beds,  
A thousand thousand heads,  
Their richest, rarest store  
Yield freely to her bore,  
In stills, the plans her own,  
By alchemy unknown,  
With mingled suns and dews,  
Untaught of us, she brews  
Delicious honey.

Who taught the bee, you ask,  
The skill for her queer task?  
Who gave her the high art  
To fashion every part,  
And, forming cell on cell,  
Build all so strong and well?  
Who told her how to sip  
The nectar with her lip?  
In garden and in field  
To find the sweets they yield?  
Who gave her the strange power,  
The alchemistic dower?  
Who gave the pretty bee  
Her power of chemistry?  
Who showed her how to take  
A thousand sweets, and make  
Delicious honey?

A moment, let us see  
This busy beauteous bee,  
Behold her and her comb,  
A self-constructed home,  
Each single rounded cell  
Is builded strong and well,  
While all the solid walls  
Rival old St. Paul's,  
Unschooled, the little bee  
Excels yourself and me;  
Without mistake or flaw,  
By instinct's certain law  
She builds, and, building, shows  
How much she really knows,  
In hives and barns and attics,  
Of simple mathematics.  
With never fuss nor fret,  
She works for what we get—  
Delicious honey.

## THE NEED OF GOOD QUEENS IN JAMAICA.

If any country requires better queens than another, it is Jamaica. Why? Well, our honey-flow is never as heavy as with you in the States, but it is continuous for, say, seven months, and all that time the queen is hard at work keeping up egg-laying. A queen is old here at twelve months of age.

JAMAICA BEE-SUPPLY CO.

Mandeville, Jamaica, Ang. 23.

J. H. B., Utah.—Young larvæ having their heads wrong end to in the cells is very unusual. We would advise you to change queens.

W. W., Mass.—The insect that you send us is what is known as the "robber-fly," *Asilus Missouriensis*. It is common in the South, but is very rarely seen in the North. While it preys upon bees to some extent it does no great damage. It also destroys thousands of noxious insects, and it is possible that the good it does more than overbalances the harm that it does to bee-keepers.

J. M., Wis.—There are two ways in which you can winter your bees—out of doors and indoors. If you winter outside, the spaces in your double-walled hives should be packed with sawdust, planer-shavings, or some porous material. In the absence of anything else, dry leaves packed pretty solid will do nicely. For directions in regard to wintering, see page 34 of our catalog, and also the subject of "Wintering," in our A B C of Bee Culture.

C. S., N. Y.—In regard to the microscope, and slides showing bees, I am now a little rusty on the subject, not having done any thing at it for some twelve or fifteen years; but I think there is no question but that, for the money, you can get altogether the best microscope from the Bausch & Lomb Optical Co., Rochester, N. Y. Their microscopes are well made, and the lenses are fine. Send for their catalog. With regard to slides showing bees, I do not know to whom to refer you. I have a very choice collection of my own that I made, but which I should not like to part with, as I sometimes wish to show them to bee-keeping friends who call here. Regarding the price of microscopes, I do not believe you can get a really good one for less than \$15 or \$20. The more money you pay, the better the instrument.

C. K., Texas.—The amount of sulphuric acid to be used in refining wax varies with the quality of the wax. If it is dark and dirty, use about a pint to two or three pails of water. If it is fairly clean, and needs only to be of a lemon yellow, a very little acid will answer. A tablespoonful to a pail of water might be sufficient. You may have to "cut and try" until you get about the right proportion. It is desirable to use as little acid as possible to secure the result; then the melting tank or barrel should be allowed to stand, covered with carpets or old cloths for a few hours before the wax is drawn off. If it is a barrel it would be more practicable, probably, to dip it off from the top. Before dipping, the wax should be cool enough to form quite a scum on top. When it is allowed to stand thus, the impurities go with the sulphuric acid, and settle out of the way by reason of their greater specific gravity.

SOMEBODY has been calling Dr. Miller a liar. I do not believe he believes he is one, neither does any one else unless it is the fellow who gave him that mild appellation. Take it all in all, I believe I would rather have a man call me a harsh name than my friends all know doesn't fit than to fling mild insinuations at me that border pretty closely on the truth.

A PAPER by the Hon. R. L. Taylor, of Lapeer, Mich., formerly experimenter for the Michigan State Apiary, on the relation of bees to horticulture, was read by the president, Mr. Taylor being absent. In this paper he touched upon the subject of spraying and the pollenization of fruit-blossoms by bees. It was one of the ablest and best papers that was ever read on that subject; and if no one has any objections I propose having it put in the form of a leaflet for general distribution among farmers and fruit-growers. I hope to present it to our readers a little later on.

A FEW days ago we had a pleasant visit from the editor of the *Pacific Bee Journal*, Mr. B. S. K. Bennett. Having been through a hard rush of business publishing and editing the bee-journal, and conducting the supply-business, at Los Angeles, Cal., he found the need of a rest, and accordingly had been taking a sojourn of two months in the East, among friends and relatives. As previously announced, he attended the Buffalo convention, and went from there on eastward, and finally in his circle landed here at the Home of the Honey-bees. He was just on his way back to the Pacific coast, and left Medina for a bee-line to his home. Mr. Bennett is only 24 years old, but has considerable business sagacity and push. As editor of a bee-journal and as a short editorial paragrapher he has shown no mean ability. GLEANINGS wishes him success.

#### BEE-KEEPERS' PICNICS AND GOOD COOKS.

A BEE-KEEPERS' picnic is quite a common social affair in York State. I have attended several of them myself. The last issue of the *Amer. Bee Jour.* refers to one held recently at Freeville, and which I attended. It seems that there are several counties in York State that have county bee-keepers' associations that meet at least once a year. It is the custom to call in some outsider to address the association, after which there is a general discussion and question-box work. This is either followed or preceded by a first-class picnic dinner. I said "first-class," and I meant it, for those York State women do know how to cook. I remember that the president of the Seneca Co. Bee-keepers' Association, Mr. Fred S. Emens, at the last meeting at Elm Beech

Park, was asked what he thought of the Seneca Co. cooks. I couldn't see the "point," notwithstanding every one laughed. Noticing my blank silence, some one whispered in my ear that the president was a single man, and that there were also some "good-looking single cooks" there that day. My eyes involuntarily wandered from good-looking Fred to the aforesaid prepossessing cooks, and I said to myself, "Yes, why not —?"

#### BEEES LOOSE IN THE POSTOFFICE IN NEW YORK CITY.

ALONG the fore part of last month appeared an item in the *World*, of New York, to the effect that some bees had caused a panic in the New York postoffice. It seems some ignoramus of a bee-keeper had put up a lot of bees in a flimsy package that leaked, and the bees got loose in the mail-sack. When the clerks in the New York office (probably the most important one in the United States) attempted to open the sack, there was a "panic;" and the *World* for Sept. 8 gives an account of it as follows:

The clerks who sort Uncle Sam's mail in the big granite Federal Building had the liveliest sort of a time for an hour or two last Saturday night.

Along about midnight, when the work is the heaviest, and van-load after van-load of mail-matter is dumped in the postoffice, to be sorted by the army of clerks, a porter hopped a big leather pouch on a "form," as the sorting-tables are called, and proceeded to open it.

As he slipped the leather strap through the staples and pulled open the mouth of the pouch he heard a sound he had never noticed before to proceed from a mail-bag. It was like the humming of the summer breeze through the tree-tops.

"That sounds like mosquitoes," said the porter, who lives in Hackensack in the winter season; but he backed away from the pouch and called a fellow-porter's attention to it.

The two made a cautious investigation. The sound had ceased, however, and one of the porters ran his hand inside the pouch and felt around for about two seconds. Then he let out a yell that alarmed the roomful of clerks, and danced about the sorting-table shaking his hand violently.

"Take 'em off!" he yelled, and he tried to brush something from his hand.

"What's the matter, Bill?" asked his friend.

"Bees, that's what! There's a million of 'em in that bag."

The superintendent was called, and a council of war was held. It was decided that bees or no bees, that bag of mail had to be sorted, and volunteers were called for.

After considerable hanging back, two brave fellows grabbed the pouch and emptied its contents on the "form."

As the letters and packages poured out on the table a swarm of healthy "workers," as the apiarists call them, arose in a cloud and sent the clerks scurrying to cover.

Several felt the result of contact with the business ends of the honey-makers, and it was some time before the volunteers screwed up courage enough to return to their work. The mail-matter had to be separated, and that quickly, for already much time had been lost.

It is evident that the facetious reporter drew largely on his imagination, and that the actual occurrence was not nearly as bad as reported; but it was bad enough. It was just such an occurrence as this that resulted in Uncle Sam's prohibiting bees from the mails a few years ago. Any bee-keeper who is careless enough to put up a package of queen and bees so that it breaks open in the mail-bag should receive a good scoring.

## BEE-KEEPING IN HAWAII.

We have had a pleasant call from Mr. Wm. Thompson, of Honolulu, H. I. Mr. T., although connected with the "Kamehameha" school, and instructor in the department of sciences, is the owner and manager of some 500 colonies of bees, all in one apiary. Two things I could not understand. 1. How he could manage to teach every day, and run so large an apiary; 2. How it was possible for him to keep so many colonies in one apiary. As to the first, he is obliged to employ help; and, moreover, the heaviest part of the bee-work comes when school work is the lightest. As to the second, he told me that he presumed he had too many, but that many more colonies could be supported on a given location in Hawaii than in many portions of the United States. Bee-keeping was confined to a narrow belt of land along the coast, and a company had been formed to buy up all the colonies in that region, the ostensible purpose being to "make a corner" on the honey market there, and at the same time secure all available desirable bee-pasturage, for it seems that that is quite limited. The area which the company is trying to secure control of will probably support only about 3000 colonies. They have not pulled Mr. Thompson into the "combine" yet, and it is unlikely that they will succeed in doing so.

Our friend says that bees can be kept inland, or up in the mountains, but the honey is dark and of poor quality. That which is produced in the area along the line of the coast is of very fine quality, if I can judge from the taste of a mere sample which he gave me.

We have sent him queens a number of times by mail, and I believe that in all cases they have gone through alive; but imagine my surprise when he said that the bees, even from these queens, grow to be so large in the salubrious climate of the Hawaiian Islands that they can not go through ordinary perforated zinc. I had asked him if they used perforated zinc, and he said he had tried it, but had had to give it up, as the bees could not get through it when filled with honey; and then when I suggested that the bees from *our* queens surely could, he shook his head.

The honey that is produced in Hawaii is all extracted, and is sold in the London markets. The beeswax, also quite an item, instead of being a bright yellow as it is in this country, is white—so white, indeed, that its purity has been suspected in London; but when it is remembered that this wax comes from the solar wax-extractor, and that said extractors are under a tropical sun, it is not to be much wondered at that the product should be thoroughly bleached.

Mr. Thompson gave me an interesting account of the situation in Hawaii, and of the struggles of the little republic under our previous and present administrations; of the wisdom and magnanimity displayed by President Dole, under trying circumstances. Of course, friend Thompson was heartily in favor of annexation, and he hoped that our American Congress would make the little republic a part of us.

## THE BUFFALO-CONVENTION PICTURE.

AFTER one of the sessions, somewhere about four o'clock, the bee-keepers assembled in the convention room at Buffalo were requested to adjourn to a raised platform in front of the building, and near one of the triumphal arches through which the G. A. R. veterans marched. The bee-keepers were requested to take their seats upon the reviewing-stand, while the artist took two shots; but as it was a little late he made a little too much allowance for the light, and "overtimed" the pictures so that they were too flat or too something; but on the morning of the same day, I think, the same artist took a view of a large number of the bee-keepers who attended the convention that was good. This picture was taken in front of the lodging-house where many of us were stopping; and the result in half-tone is reproduced on another page. This view, while it shows only a small portion of the convention members, takes in a list of many of the most prominent bee-keepers of the country. I regret that I am not able to give you the name of each one of the faces there shown, and I can remember only a few of the more prominent ones.

Beginning at the extreme left, the bald-headed gentleman with full-face, white tie, and side whiskers, light coat, arms folded, apparently leaning on the steps railing, is Mr. Wm. Couse, a gentleman who has long been secretary of the Ontario Bee-keepers' Association. He is one of the leading bee-keepers of Canada.

The gentleman just in front of him with arms also folded is Mr. S. A. Niver, or, as he modestly styles himself, "Morton's brother-in-law." Mr. N. has had much experience in selling honey and other articles directly to consumers. Possessed with a good stock of humor and with a "tongue balanced in the middle," he can sell honey like hot cakes.

The next face that I recognize, and just at the left of Mr. Couse, and a little higher up on the steps, with his hands folded in front of him, is Mr. E. T. Abbott, editor of the *Busy Bee*, a sprightly publication published at St. Joseph, Mo. Mr. Abbott, as I have before stated, is employed by his State to lecture on rural subjects during the winter. I never heard one of these lectures, but I have seen some of those who have, and they pronounce them as full of life and interest. His hen story, it is said, fairly captivates his audiences.

Mr. A. is always prominent at conventions, is an eloquent and earnest speaker. Very often independent in his views he says just what he thinks. If the "other fellow" does not like his style—well, he does not lose any sleep over it. While he may not be given to honey-eyed words he has a kindly heart and sympathetic nature.

At Mr. Abbott's left, and just in front of one of the pillars, is Mr. David Coggsball, who, I believe, owns an apiary of some 500 or 600 colonies of bees. Like his brother, W. L., he lives in a beautiful residence—one that would compare favorably with some of the dwellings on the fashionable streets of our cities. Both of the Coggsballs are bright keen

business farmers—at least I judge them to be such from the general thrift and appearance of every thing upon their premises. There were no broken-down gates, tumble-down fences, no poor excuses of barns, or houses sadly in need of paint.

At Mr. Coggsshall's left is Mrs. Mason, wife of Dr. A. B. Mason, the enterprising secretary of the U. S. B. K. U. The doctor is one of those whole-souled, happy, good-natured men whom it is a pleasure to know; and while his face beams all over with smiles, he is quite liable to say something that will hit *you*, if you do not look out. If you do not like it—well, he is too fat and happy, he says, to worry very much about it. Mrs. Mason is one of those quiet, pleasant women, whom it is a pleasure to meet. She very often goes with her husband to bee-conventions, and the doctor says he takes her along to keep *him* straight.

In front of Mrs. Mason, with his arm resting upon the railing, and sitting down, is the kindly face of Dr. Miller. He is another strong convention man. Without him, a convention to me always has something lacking. The doctor has a happy faculty of throwing in jokes and short pithy speeches that help very much to enliven a convention.

Just back of Dr. Miller, and next to Mrs. Mason, is Geo. W. York, president of the U. S. B. K. U., and editor of the *American Bee Journal*. He was again honored with the office, and will probably be our presiding officer at the next meeting at Cincinnati or Omaha, or wherever it may be held. Mr. York is a little chap; but what he lacks in stature is made up in energy and hard work. If he loves his friends he loves them with all his heart. He never believes in doing any thing half way.

At Mr. York's left, and in the background, a little to the right of the middle pillar, is Mr. E. A. Wander, of Hartford, Ct. I made his acquaintance at the Buffalo convention, and had the pleasure of his company at Niagara Falls. He is royal good company.

In front of Mr. Wander is Mr. O. O. Poppleton, a bee-keeper of national reputation, of wide experience in the North and the South—one who, while he does not write very much for the journals, yet, when he does write, has something to say. He is a very careful, thoughtful bee-keeper. So careful and conservative is he that he has been engaged to make some experiments for us for a year or so back, in testing various articles that we were about to put on the market, but which we could not do in our northern climate.

Next to Mr. Wander, and back of Mr. Poppleton, almost too much in the shade to be seen distinctly, appears Mr. P. H. Elwood, of Starkville, N. Y. He is a large man of fine appearance; nor does this exterior belie his real heart. With the possible exception of Mr. W. L. Coggsshall, just in front of him, and a little to his left, he owns and operates the largest number of colonies of any bee-keeper represented in this view. In general characteristics he and Mr. Poppleton are a good deal alike—careful, conservative. He is too busy to write much for the journals, and

too modest to say much in conventions. But when he does express himself he gives us something to think about.

Just in front of him, with his elbow resting on the railing, is Mr. W. L. Coggsshall. In our previous issue I referred to the rapid way in which he and his helpers handle bees; and as I expect to write up more in detail in future in regard to Mr. C.'s methods, I will not say more about him at this time.

The next face that I recognize on the porch is that of Mr. Miles Morton, of Groton, N. Y., who is the "brother-in-law" of Mr. Niver. Mr. Morton has been for years the local supply-dealer in Tompkins Co. During my recent visit to New York State I called at his place. Like the Coggsshalls he has a beautiful home, and in the rear a nicely equipped shop for making hives, sections, etc. Mr. Morton must be another Dr. Tinker, for it is easy to see he is a born mechanic. Every thing turned out from his shop is beautifully smooth and accurate. He is a man of original ideas, and in his quiet way he has been using and advocating certain devices which, in my humble judgment, will in the near future come to the front. But more of this at another time.

Getting off from the porch, and just in front of the pillar on the right, with his hands behind him and his hat on, is the Hon. E. Whitcomb, vice-president of the U. S. B. K. U. He had come all the way from Friend, Neb. For years he has been one of the active bee-keepers of his State; and the handle to his name shows that he has dabbled more or less in politics. I took a walk with him through the streets of Lincoln, Neb., and found that he is known familiarly pretty well over the city. He introduced several of us to Senator Thurston, of the U. S. Senate; and I could not help noting on all occasions that one and all seemed to feel that Mr. Whitcomb was a man of influence.

Just in front of Mr. Whitcomb, and a little to the right, with his back against the railing, and his head between two flags, stands R. F. Holtermann, editor of the *Canadian Bee Journal*, and apicultural experimenter of the Ontario Agricultural College. Mr. Holtermann, although a young man, has been honored with the office of president of the North American Bee-keepers' Association, and has also been its secretary. For one and possibly two years he has been president of the O. B. K. A., and for years has been recognized as one of the leading bee-keepers of Canada. He is active in conventions, and writes to a considerable extent for the agricultural press.

Just in front of Mr. Holtermann, and a little to his right, stands Mr. Frank Benton. This gentleman has probably traveled more miles after big and little bees, passed through more real hardships, and has probably seen more of the apicultural world in this and other lands, than any other living man. It was he who accompanied D. A. Jones, and acted as interpreter for that gentleman in a trip through Europe and to the Holy Land after eastern bees, the result of which trip was the introduction of Syrian and Cyprian bees into

this country; and it was Mr. Benton who went through the jungles of India after *Apis dorsata*, studied them in their native homes, and sent back reports at various times in regard to these and other species of bees. He is probably more intimately acquainted with the different bees of the world than any other man living. At the present time he is connected with the Agricultural Department of general government, in the Division of Entomology. Mr. Benton is exceptionally well educated, reading and speaking fluently several different languages. He is a fine conversationalist and a direct and forcible speaker; and were it not for some unfortunate things that have happened at recent conventions (whether he was right or wrong I need not discuss) he would be one of the most popular men in our ranks.

There, I believe I have given all the names than I can remember. There are some faces among those above that seem familiar to me, but at this time and place I can not locate them for I am not good at remembering names, especially if they are piled upon at the rate of four or five a minute.

This picture does not by any means represent all the leading bee-keepers who attended the convention at Buffalo; but when I come to review in my own mind the lives of a few of our leading lights, I feel proud of our industry and of the men who represent it; and in my travels among bee-keepers I am more and more convinced of the fact that they are superior men and women. A large number are leaders in some of our best professions. No wonder, then, that they are shining lights in the bee-keeping world.

#### ROTTEN BROOD IN THE APIARY; SENDING SPECIMENS TO MEDINA FOR IDENTIFICATION.

THE foul-brood inspector for Ontario, Canada, Mr. Wm. McEvoy, in the *American Bee Journal* for June 17, makes the following good points:

For 17 years I have warned the bee-keepers to keep all dead and putrid matter out of their colonies, so as not to cause foul brood; and while I have been warning and holding up Death's head and the cross-bones, the professional guessers, who were not practical bee-keepers, have been encouraging the wholesale spread of the disease by saying that rotten brood in hives would not cause foul brood. Such teaching as that has caused thousands of bee-keepers to be very careless; and when the disease has broken out in their bee-yards, it was left to run its course to the ruin of their apiaries, and all others in the same localities. It is only the very few among many thousands of bee-keepers who have succeeded in curing their apiaries of foul brood after it got a good start in their beeyards, and the owners left to themselves to manage the curing.

It is certainly wise to err on the safe side; and while rotten brood may not necessarily be foul brood, nor be capable of developing into that disease, yet it should always be looked upon with suspicion by the bee-keeper, especially if he does not know exactly what the disease is.

I have advised bee-keepers of late to send us doubtful samples for identification. Of course, such pieces of comb should be securely wrapped, preferably in paraffined or waxed paper. If you can't get either of these, get

some stout paper and grease it on both sides. Never think of sending brood wrapped in paper simply, or in a paper box. After wrapping as directed, slip it in a tin box, the comb packed in cotton batting. This latter is to act as an absorbent should there be any dripping.

Two or three samples without the box came to us with the paper soaked through and dripping; but happily the specimens were not foul brood. We are quite willing to help our subscribers all we can; but we do not wish to place our own bees and our own interests in jeopardy.

Each sample of brood is thoroughly inspected, and a report is made in regard to its condition by return mail. It is my practice to take a doubtful sample, go before the big boiler-arches, open up the packet, smell it, tear open the cells with a little sliver of wood, and then toss the whole thing, package and all, into the raging fire. We burn all such specimens, whether they prove to have foul brood or not.

One man was about to destroy his whole apiary, thinking he had foul brood. At my request he sent me a sample, and it proved to be only chilled brood—brood that had died owing to the cool nights prevalent in the latter part of May. I told him the bees were all right, and to let them alone. How much we saved this man the reader can figure out for himself.

I have given similar advice to several others, and am willing to do it again; but our friends must not put us in jeopardy by putting up the specimens carelessly.

#### KEEPING HONEY OVER FOR BETTER PRICES.

MR. J. F. MCINTYRE, of Fillmore, Cal., who was present at the Buffalo convention, told us how he stored his honey in large storage-tanks, and held it over for another season. If the market prices did not seem to justify him in disposing of it that year he held it over. The honey-flow in California is very uncertain. A good year is liable to be followed by a poor one. It is the year following, possibly a poor one, when honey is a scarce article, that Mr. McIntyre unloads his crop at paying prices. The white-sage honey is not inclined to candy, and he finds it profitable for him to store it over till prices suit him. He said he could keep honey stored in his large tank some two or three years without candying, and he could afford to wait till the market went up.

Some one, in the course of his talk at the convention, asked him what his honey crop was. Year before last he had one thousand 60-lb. cans of honey. It is well known that California bee-keepers wholesale and retail in square cans holding 60 lbs. On account of the dry climate, barrels and kegs can not be used. Well, those thousand 60-lb. cans, or 60,000 lbs. of honey, was all produced from one apiary. This apiary is located in a valley, and comprises some 500 or 600 colonies. He narrated how the bees would fly six and even seven miles up and down the mountains. Those long flights explain why so many bees can be kept profitably in one apiary.

Our older readers will remember Mr. Fred L. Craycraft, who used to write for the *JUVENILE GLEANINGS* when we had a "juvenile" issue, fifteen years ago. Well, you may not all know that Fred has grown to be a bee-keeper of no small "dimensions;" in fact, he is at present the owner of an apiary of something like 500 or 600 colonies in the island of Cuba. Well, just before the convention at Buffalo we were agreeably surprised to meet this same person here at the Home of the Honey-bees, and he accompanied us on the way to Buffalo. As he is quite a cyclist he accompanied me on a pleasure-trip to the vicinity of Niagara Falls. I hardly need tell you of the beautiful path for wheelers from Buffalo to the Falls. We, however, branched off from the regular route in order to call at Christian Weckesser's, at Sanborn, N. Y. Friend W. is a seed-grower and market-gardener, and of course I greatly enjoyed looking over his vegetables and fruits. Like myself, however, friend W. finds that, in attempting to grow all kinds of fruits and vegetables, he has a pretty big job on his hands; and when it comes to growing seeds for sale *also*, I tell you one has most of the time too many irons in the fire, especially if he wants to take a little time now and then to get acquainted with his wife and children. Friend W. has the wife and children too, and we had quite a pleasant talk about "our homes" as well as about our vegetables and fruits. Plums were just getting ripe at the time of our visit, and I for one greatly enjoyed sampling varieties I had read about but never saw or tasted before.

I can not tell you of all the new things I saw there; but I want to mention Kendall's Giant sweet corn—a variety as early as, or, if any thing, more so, than the Corey, and at the same time producing good-sized ears free from the smut, that seems to hang about the Corey so persistently. I saw it growing, and examined the ears, as I did also the Corey planted at the same time and on the same ground. I am so well satisfied of its superiority that I expect to offer it for sale next season in place of the old standard Corey.

Our next point was La Salle, near Niagara, where that well-known writer and author on every thing pertaining to gardening, Tuscio Greiner, has his abode. Friend Weckesser kindly volunteered to go with us to La Salle; but it was just about dusk when we reached there, and Mr. Greiner was absent at Buffalo. However, we greatly enjoyed looking over the grounds. No wonder things grow, for the beautiful soil was so filled with stable manure that it made me think of the grounds around Arlington, in the suburbs of Boston. We saw the various things friend Greiner has told us about in his articles in the different agricultural periodicals; the house for curing onions, open at the sides, with broad roof to keep off

the rain; the beautiful onions on their respective trays where they were being cured preparatory to pickling; the great Prizetakers, grown by the new onion-culture process, showing that friend Greiner practices just what he preaches. I also greatly admired the white onion called Garganus. This I saw both here and at friend Weckesser's grounds. It is larger than the Prizetaker, and it seems to me the onions are more uniform and true to type. And, by the way, we talked about the fact that the seed of any vegetable, when it is first introduced, is greatly superior to any that can be bought a few years later. We also saw where friend Greiner had grown onion-plants in his greenhouse, in *coal ashes*, and nothing else. This seems to me a little astonishing. Mr. Weckesser said he saw them at different stages of growth. The onions are of better color and of better growth than when produced in the rich greenhouse soil.

When I spoke about going to a hotel for the night my good friend Weckesser replied:

"Mr. Root, you trust me a little, and don't do any thing about going to a hotel just yet. There is a man who lives here whom I want you to see; in fact, I am expecting something rich when you two get a little acquainted."

On the way to the place mentioned we passed a store, beautifully lighted, as I supposed, by an electric light inside, and another one out in the porch.

"There, what do you think of that light?"

"Why," said I, "it is a very pretty light indeed. Is it some new method of using electricity for illuminating?"

"Mr. Root, it is not electricity at all. Just take a good look at it and we will go on."

We drew up in the darkness in front of a very pretty residence; and when told that Mr. Long was at home he invited us to go in. Before we entered the apartment there was a little hustling around as if something had been carried out of the room, and I soon became aware of a peculiar smell of chemicals that brought vividly to mind my boyhood days. When I asked about it our host admitted they had just carried out some of the chemical apparatus, but suggested that perhaps it would please *me* as well to have it brought back. Then one of the boys brought in a sort of lamp made of tin, surmounted by a gas-jet. This gas-jet gave forth a small blue flame. It looked to me like the flame produced by the oxy-hydrogen blowpipe of forty years ago, especially when said blowpipe was directed against a piece of lime or other refractory substance.

"May I ask what gas it is that is giving this exceedingly brilliant flame?"

"Mr. Root, you say you studied chemistry once. Let me explain it briefly by saying that it is the new acetylene gas. Its chemical composition is expressed by the formula  $C^2H^2$ ;\* as you may know."

"Why," said I, "it is one of the hydrocarbons, like illuminating-gas, only you have

\* Illuminating-gas is, if I am correct, light carbureted hydrogen,  $C^2H^4$ ; thus it contains double the amount of hydrogen found in acetylene gas.

a larger percentage of hydrogen. Is it a new discovery?"

"No. Acetylene gas has been known for years. You probably saw it mentioned briefly in your chemistry forty years ago; but since Niagara has been harnessed, and we have electrical energy in greater volume, and cheaper than the world ever saw it before, some odd things have come to light. About four years ago, while attempting to produce something that was wanted, a quantity of lime and carbon was exposed to this tremendous electric heat; but they did not succeed in producing what they expected, and the product of their experiments was thrown away. When some water was accidentally thrown on to this substance a very curious phenomenon ensued. Here. Examine this piece of stone, will you?"

The mineral that I took in my hands looked like limestone. After I had examined it sufficiently, one of the boys handed Mr. Long a bit of ice perhaps as large as a hickorynut. Another gave him a match, and, after placing the lump of ice on the limestone (as it appeared), a lighted match was held over it. The ice took fire like a piece of resinous pitch, and burned up with wonderful brilliancy. When the ice was all consumed, the fire went out. Next a piece of this new mineral, calcium carbide, was dumped into a tub of water, and quite an ebullition commenced at once. When a lighted match was applied to the surface of the water we had a fountain of flame. This calcium carbide liberates pure acetylene gas just as soon as a drop of water touches it; and the lamp that friend Long has been engaged in perfecting is simply a tin can to hold the new chemical. You just pour some water on the limestone, screw on the top of the lamp containing the burner, and it is ready to light. When you turn off the gas, so that no more can escape, it accumulates and pushes the water up into the reservoir above until no more touches the lime; then the gas ceases to be generated until somebody opens the burner and lets some of it out; so you see it is automatic in its operation. The gas is generated just as fast as it is burned, and no faster.

Permit me to say right here, that, when I was seventeen years old, I was astonishing the people right and left by showing experiments in electricity and chemistry. I used to go around to the schoolhouses, charging ten cents admittance—schoolchildren half price. During the forty years that have passed since that time I have kept track, more or less, of the developments in electricity. No wonder friend Long and I talked far into the night. I am afraid I forgot all about our friends Weckesser and Craycraft and all the rest. They dropped off one by one, and left us talking.

This calcium carbide is now produced in a large factory at Niagara Falls. It is offered for sale in quantities at four cents a pound; and it takes so little of the gas to make a tremendous light that four cents' worth of material will do more lighting than a like amount of money expended in kerosene oil, cheap as it is in many places. Instead of filling your lamp with oil you take out the slacked lime and put in another chunk, something as you

slip a cartridge into a gun, and that is all there is to it. There is nothing greasy or wet or sticky about the apparatus, or will not be when it is perfected. If you wish to know more about acetylene, write to D. N. Long, La Salle, N. Y. I believe a complete lamp at present costs four or five dollars. I expect to have one as soon as they are prepared to offer them to the public.

I told you in our last issue why we abandoned our wheels the next morning. Although I have several times visited Niagara I had not until this time made the trip clear under and through the falls. During my previous visit I believe I did not get enough of its wetness and grandeur. Friend Craycraft and I, however, decided to take it all in. We took off every thread of our ordinary clothing, and put on something like bathing-suits; and over these, suits of yellow oilcloth, including a hood that came clear over the head. As I am susceptible to chills, I was a little fearful, when I walked along the slippery walk, of the cold spring water trickling down upon us; but when I got far enough into the water of the great cataract I was surprised to find it comfortably warm, even on a somewhat chilly morning. We first went clear around the fall through the spray, witnessing the rainbow that makes a complete circle. They claim this is the only place in the world where one can see a rainbow that goes clear around like a wheel. Outside of this is a second rainbow, and part of the way round you can see a third one. I have many times wished it were possible to go right into and through the falling water; but I did not know before that this had been done so completely. I experienced at first the pleasurable sensation I have so often described, of breathing watery spray. But pretty soon there was more water in proportion to the air than was really agreeable. I began to be afraid I should strangle, and asked the guide and friend Craycraft if they were prepared to carry me out if I fainted from loss of breath. After they had expressed their readiness and *ability* to take me safely through, I ventured onward. Just imagine yourself outdoors in the most pelting rain you ever saw; then suppose the raindrops to be so thick that there is more water than air. It was a sort of spray; but this spray came in such volume that, when the guide told me to look straight down, it seemed to me as if the weight of the water would crush me to the earth, or, rather, to the stout iron bridge on which we were walking. Occasionally the water would swing over to one side so I could look up. No tongue can describe nor pen picture the sight. The water seemed like billows of snow. In fact, it made me think of the roaring and tumbling snowdrifts that I saw through a telescope over Pike's Peak. Yes, I was "right in the swim" of Niagara Falls; and it seemed as if one *might* almost swim in this watery spray. I wondered who it was who was sufficiently daring to undertake to construct the iron bridge right through this boiling mass of water. Did the workmen get accustomed to it? or did they choose some time when the great cataract was asleep, and

forgot to pour down its terrible and *relentless* stream? Panting and gasping I said to the guide, "Do we have to go back the way we came?"

"Oh! bless you, no. We go in one way and come out the other. You have got all through it;" and for the time I was glad. Yes, I paid a dollar for the privilege of going "behind the curtains," and being for a few brief moments right in the midst of the roaring and seething monster. And it was worth a dollar too. I shall never forget it; but I do not want to go through it again, even if the guide did say, "After you have been through three or four times you can breathe without any trouble at all. One has to get used to it."

Our guide seemed to be quite a sensible, intelligent, and bright fellow, and I felt a good deal of respect for him until just as we reached the top of the stairway, when he said, "It is customary for *gentlemen* to remember the guide before they go away, by some remuneration for his services."

You pay a dollar for the privilege of going under and through the falls. This is fully explained in circulars, and at the office before you go down; but not a word is said to the effect that you are expected to pay any more after you have paid a dollar; and I would suggest to the proprietors of the aforesaid institution, that, if they wish to preserve the respect and confidence of their patrons, they will put a stop to this sort of begging for a little more money. If I am correct, the whole thing is getting to be in disrepute. After you have paid the advertised prices at a hotel, in a Pullman car, or anywhere else, you are not expected to pay the waiter or porter something extra for being *decently* waited on. I told the guide I did not believe in that sort of way of doing business, and did not think it my duty to encourage or sanction it.

HOW HUGH VANKIRK, OF WASHINGTON, PA.,  
GETS 20 CTS. A POUND FOR HIS HONEY,  
BOTH COMB AND EXTRACTED.

In the first place, he produces from the white clover on those Pennsylvania hills about the finest article of clover honey I ever saw or tasted. He works his apiaries for both comb and extracted honey. The former is cut out of the frames or sections, and put into glass jars, and the liquid honey is poured around it. All this may be quite familiar to you; but when he showed me one of his jars containing 3 lbs. of honey, I raised my hands and uttered an exclamation of surprise. The jar, I should think, is flint glass. It is made by the Hazel Glass Co., Washington, Pa., and the cost, I think, was only about 7 cts. apiece.

Of course, this is almost twice as much as the cheap Mason jars; but if it has the effect of making the *honey* sell for almost twice as much, we can well afford the extra expense of the jar. The honey is put up only as fast as it is sold. None of it is allowed to candy on the dealer's hands; neither is said dealer given so many jars at once that they get dusty and flyspecked, etc. When I took one of the jars in my hand I was almost ready to say I would give 60 cts. for such a jar of honey, just be-

cause it looked so pretty; and when my friend took off the cover and handed me a spoon, and asked me to taste it, then I was fully satisfied to pay 60 cts. for it just to put on my own table. May be my long wheelride had given me an appetite for honey, and an appreciation for nice-looking things; but it seemed to me then I had never before found any honey equal to that, both in looks and in taste. Friend V. insinuates that there is not anywhere in the world any honey equal to that from the Pennsylvania *hills*; and that is a pretty good way to think of one's own locality. Of course, the price of the jar has to come out of the 3 lbs. of honey; and when he leaves it at the stores he gives them 10 cts. commission on each jar they sell; but where he carries it around to the houses, and retails it out, he actually gets 20 cts. a pound for his honey, package thrown in, as I have explained.

Now, then, what is to hinder people in other places from getting a like fancy price for an equally "gilt-edged" product? This clover honey was not as white as the California sage, but it had a beautiful crystalline amber appearance, even though it was so thick that a spoonful could be turned over safely, even during a warm day, without danger of dripping. I will tell you more about friend Vankirk some other time.

---

## OUR NEIGHBORS.

---

Thou shalt have no other gods before me. . . . For I the Lord thy God am a jealous God, visiting the iniquity of the fathers upon the children unto the third and fourth generation of them that hate me, and showing mercy unto thousands of them that love me and keep my commandments.—EXODUS 20 : 3, 5, 6.

I had been having a 25-mile ride on the wheel, the latter part of it over some very long hills. My destination was Silver Lake, Summit Co., Ohio. I sat in an easy-chair to rest after my fatiguing ride, and was having a pleasant chat with the proprietor of the place. Suddenly somebody called him to the telephone, and a minute later he seemed somewhat disturbed, and asked me to get my hat and follow him quickly. I did so, and on our way through the darkness he explained to me that his boys had just rescued a woman on the opposite shore of the lake. They heard something on the other side, and sprang into the electric launch, which was all ready to shoot out into the water with incredible speed by simply pressing a button. They very soon reached the point whence the sounds proceeded. A woman was in the water, and they had rescued her. By the time he had finished telling me about it we were down at the landing. The boys had carried her into one of the buildings; and while the women-folks were busy in getting her a change of clothing, several attempts were made to talk with her; but she did not seem inclined to speak. She was a young woman, well dressed, and of attractive appearance. I decided in my own mind from the first that it was an attempt at suicide. And then I began wondering, as I looked upon her, how it was possible that one just in the

prime of life, with every thing, apparently, to make one rejoice in living, should desire to throw away this wonderful and precious gift from God. While these thoughts were in my mind it seemed to me that I could approach her in such a way that she would speak. I leaned over her, and said something like this :

"My poor friend, we know nothing about what it is that troubles you ; yet God knows, and he only can help you in a time like this. Will you not put your trust in him?"

She thanked me ; and when I asked her what we could do for her she requested to be sent home, and gave me her street and number. The doctor was soon at hand, and pronounced her in a nervous chill. She was dressed in dry warm clothing, and sent to her home. The daily papers afterward announced that it was, as I had suspected, an attempt at suicide. She was engaged to be married to a young man from Toledo ; but just on the eve of the wedding he disappeared, and she afterward learned that he was already married.

Things of this kind have happened so often you wonder why I take the trouble to mention it. I will tell you. In thinking it over I felt impressed that it was my duty to plead with this poor young woman, and to use my poor powers of persuasion to induce her to choose Christ Jesus as her friend and confidant, and to cease to mourn or feel troubled about one who had shown himself so utterly unworthy of her care or regard. Some of you may smile at my simplicity. You may think I ask something that is impossible to the average young man or young woman. Dear friends, I know whereof I speak, for I have been through Satan's toils. God has given you as well as myself a human life to live. It is a great and a precious gift ; and if we are loyal and true to the great Giver, the great Father of us all, we shall so regard life. Nothing should induce us to think of throwing it away. *God gave*, and no possible combination of circumstances should make us think we have any *right* to throw away or destroy that which he gave. Satan never misses an opportunity to get into the human heart and persuade one that God conferred no favor in giving us life. In fact, I have sometimes thought that Satan's whole work is only for the purpose of getting his victim to throw away and destroy the life that God gave. We think of suicide because we have broken or begun to break this first and greatest of all the commandments, as in our text. When that smart lawyer came to the Savior and sought to test him by asking which commandment was the greatest and first of all, he replied, "Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind." This is the first and great commandment ; and through all my observation, especially since I have been trying to follow the Master, it has seemed to me the greater part of the troubles in this world are because we let something else come *before* God. This young woman had become so bound up—in fact, her whole life had become so centered in this unworthy man—that she had *forgotten* God ; and when this man proved false—when he had subjected her to that

terrible humiliation of having to come before friends and foes as a poor, deluded, disappointed woman, she felt as if she could not stand it, and she finally decided to drown her troubles in the oblivion she hoped to find beyond the grave.

Sometimes we ponder and wonder that the world has stood so long, and yet nobody knows—that is, the great part of the world at least *thinks* nobody knows—whether it is possible to escape trouble and humiliation and guilt by suicide. Even the Bible seems strangely silent on this subject. The more I study it, and the more I study humanity, the more I am satisfied that suicide *never* mends matters. Jesus himself said this was the first and greatest commandment of all. We must be loyal and true to God if we expect to be even happy in this world of ours. Many young people have an idea that such attachments, especially if they are of several years' growth, are not easily cured. I think dime novels and similar foolish romantic stories are responsible for a great part of this. A married woman who had grown-up children once confessed to me that she *could never get over* the consequence of an attachment of years before, for another than her husband. She said she could *not* keep his image out of her mind. I said to her something like this :

"Why, my dear friend, you are simply trifling and dallying with Satan. *He* is the one who has got hold of you, and will not let go. You *must* keep such thoughts out of your mind. It is almost as sinful and as wicked as for the intemperate man who says he can not control his appetite for drink. Everybody tells him, and he knows it, that it is dangerous for him to even think about it. His physician and his pastor tell him to keep busily at work at something that is good and honest ; and as he values his future life and happiness he must absolutely *pull* his thoughts from all such things. He must turn his feet away from the direction of evil, and he must put the thought far from him. He *must* do it, even if it requires prayers, groans, and tears ; and you, my friend, must do the same. You are sinning even now in telling *me* what you have told. But if you have come to me for counsel that my prayers may second your prayers, then I will do what I can for you. With Christ Jesus to help, this thing is not so *very* hard. In a very little time the dear Savior rewards the faithful and honest sufferer. I know this, for I have been in his chains. Oh that I had the persuasive power and eloquence to tell all the world, and to make it believe, that there is no *need* of being in the fetters of sin. Christ *died* that we might *live*, and that we might be *free* from sin ; and we have thousands of God's promises to the effect that whoso cometh to *him* he will never cast out."

Let me say further to those who have struggled and battled along this line, there are thousands of cases in this world of ours to show and prove conclusively that this affection—this love between the sexes—can be controlled by reason and common sense. Right among my own relatives I am quite

familiar with a case where, for many reasons of expediency, a woman married a man for whom she had no love at all. Her sister died, leaving a Christian of little children. It seemed to be a Christian duty, under peculiar circumstances, for her to take the departed mother's place. She was a Christian, and she asked God to help her do her duty. In a very little time she loved this man as much as any woman should love her husband. In fact, she said she feared in her love for him she was forgetting her Savior, for he was a very good man indeed. When Satan whispers to you that you can not stand it—that it will kill you—just say to him decidedly you are going to do your duty, even if it *does* kill. *Duty* and not inclination or feeling must rule. Our feelings are no guide in any thing unless duty and reason stand at the head.

The above thoughts were in my mind as I retired for the night. A pretty little room was given me, that opened out upon the lake, and the full moon was shining. I knelt down and thanked God, as I have thousands of times before, that he had given me a human life to live. Then I thanked him again that he had taught me the importance and the beauty of that first and great commandment. Then I prayed for the young friend who had just been rescued and brought back to life. As I stretched myself out on the beautiful soft bed that had been provided for me, a sudden feeling came over me of thanksgiving to God. Perhaps my long ride on the wheel had something to do with it. I began thinking of the pleasant sleeping-places that seemed to fall to my lot, no matter where I happened to be. Is it not a little singular that one can travel hundreds and thousands of miles, and yet, when night comes, rarely fail of finding a comfortable, pleasant, and tidy resting-place—yes, a resting-place that bears evidence of woman's touch and loving feminine hands. Again and again has it seemed to me that I did not half deserve the dainty beautiful sleeping-apartments that are placed at my disposal. May be some of these hard-working women think we men do not appreciate their efforts in this direction. If it will encourage them any I want to have them know that I at least do. Then from this I began meditating on the beautiful plan which God ordained in the creation of the sexes, and their relation one to another. Next to love to God should be the love of parents; and the love between a young man and a young woman is like the opening flower—the rosebud if you choose. It is one of the most sacred and holy influences that should move men and women. But even here Satan has a foothold. I *admire* the man who is willing to give his life, who gives himself, all he is or all he hopes to be, toward making the woman of his choice happy; but when this woman dies, or when by some strange mishap she is married to another, the man, if he is created in God's own image, should be a man *still*, and make the best of the circumstances. My mind wandered to other things that should make us happy here in this world of ours. I looked out over the beautiful Silver Lake, and then at the bright

moon sending down its genial beams; and just then, away out over the water, a beautiful melody broke forth. Somebody was singing. At first memory groped back through the dim past to recall that song of olden time; and as the singer came nearer I caught the words:

When in thy dreaming,  
Moons like these shall shine again,  
And daylight beaming,  
Prove thy dreams are vain,  
Wilt thou not, relenting,  
For thine absent lover sigh,  
In thy heart consenting  
To a prayer gone by?  
Nita! Juanita!  
Let me linger by thy side!  
Nita! Juanita!  
Be my own fair bride! \*

I had heard the melody hundreds of times in years gone by, but I never appreciated it before then. I presume the words were supposed to be those of an Indian to his dusky bride. Then I thought of the genius who gave the world not only the words but the beautiful music. Why does music touch us and stir us so wonderfully? Somebody has called it the universal language. It affects alike all tribes and all nations, no matter what language they speak. The singer of the night may have been one of more than usual talent, but perhaps not. At any rate, it gave me a new conception of the power and pathos of music; and I thanked God again and again for having made it possible for us to appreciate and enjoy this strange and beautiful thing that is called harmony. Then I thought of poetry—poetry that we find in many of our hymns and songs—poetry to make men better—at least all poetry *should* do so. Then I was permitted to take a bird's-eye view, as it were, comprising all human attainments and accomplishments, including the joys that are in store for those who love God. I never saw it spread out before me as it was on that moonlight night. And then I prayed again that, if the opportunity should offer, I might tell this young woman of whom I have been speaking, of what she tried to throw away when God in his mercy planned her rescue. It came out, as you will notice, through this new and wonderful servant of man, electricity. Friend Lodge has at his place one of the electric launches that were used at the World's Fair. Thousands upon thousands wondered to see them start in an instant with that mighty hidden power. No oarsman could have rowed a boat fast enough to rescue that drowning woman. As I sat in the seat at one time, enjoying a ride on the electric launch, the proprietor told me that under the seat where I sat were stored \$800 worth of storage batteries. These batteries are replenished by the electric current that runs the cars up to Silver Lake. The boat is ready to shoot out in an instant at any moment, day or night, and the power that may be turned on is prodigious. You and I,

\* I would not have the friends think that I entirely indorse this old song. It came out and was given to the world, if I am correct, before the advent of Gospel Hymns; but yet it delighted the young people in the years gone by; and probably through the influence of the beautiful music, to say nothing about the sentiment of the words, it may have brought cheer and brightness to many a troubled soul.

my friend, have been permitted to live in the age of electricity. We do not know what is yet coming; but we may thank God, who has permitted us to see these great conveniences, for his loving regard to us his children. All together, this little time I passed just before going to sleep on that particular night was one of the richest experiences I have ever known in my life. I have alluded to these things before, and told you that it almost seemed to me as if I were in the presence and enjoying the companionship of unseen friends—the companionship of those who know of God, and of his love to us his children. If I had been in the habit of taking drugs and stimulants I might have thought that this was the effect of something of the sort, and that there would be a reaction. No, I had not even been guilty of drinking even strong tea. The exhilaration, what there was of it, came from exercising my muscles, lungs and heart included, in riding over difficult hills just about sundown. And, besides this, I had been praying that God's kingdom *might* come, and his will *might* be done on earth as in heaven. My prayers had been answered to the extent of giving me a little glimpse of heavenly things, and I was *surprised*, but not *ungrateful*, I assure you.

#### VALUABLE RECIPES FOR A CERTAIN SUM OF MONEY.

Below we give an advertisement verbatim which appeared in a recent horticultural journal:

FRUITS, VEGETABLES, BERRIES, GRAPES, ETC., NEARLY TWICE USUAL SIZE.

Also makes melons, corn, etc., grow mammoth size. A wonderful liquid plant-food. Has never failed. Results guaranteed. Formula sent sealed for \$1. Send 2c stamp for more particulars if wanted. Reputable reference. Address  
W. H. GARRETT,  
Box 257, Mobile, Alabama.

As soon as the journal was received I promptly sent a dollar—not that I expected any thing of value, but because I am anxious to see this business stopped, of advertising recipes, etc. Below is what I received, written with a pen, as an equivalent for my dollar:

#### FORMULA.

Sulphate of iron constitutes the plant-food. Take old pieces or scraps of iron and put them into a wooden vessel, filling it about  $\frac{1}{2}$  full, and pour on water until the vessel is full. Let it stand 24 hours, then draw off and use. The vessel may be refilled a number of times with water. If the iron is not convenient take *copperas*, using one pound to four gallons of water. Suspend it in the vessel in a gunny or other coarse-fiber bag, and it will dissolve rapidly. This should be applied after the bloom falls. Pour it about the roots, using one pint on a hill of vines, and a quart on trees 2 to 6 years old, and half a gallon on those over 6 years old. This should be applied once a week until the fruit is half grown.

If used in solid form, put one ounce of copperas about the roots of the hill—not in contact with them—and for trees 2 to 4 years old, 2 ounces; and over 6 years, 4 ounces. Applications every other week for period named. Pieces of iron buried about the roots will give a constant supply.

Pear Blight.—Spread  $1\frac{1}{2}$  pounds copperas under tree out to end of limbs; or bury pieces of iron about the roots; or bore a  $\frac{3}{8}$ -inch hole into the tree and put in a teaspoonful of copperas, and plug up.  
Mobile, Ala., Aug. 31.

The above recipe may, it is true, have some value, although I am sure its value is greatly exaggerated. For years statements have ap-

peared in different periodicals, to the effect that iron filings or iron chips are valuable as a fertilizer. The fact that luxuriant and productive pear-trees are so often found closely adjoining a blacksmith shop has been adduced as proof. To test this matter we have at different times taken iron filings and iron turnings from our machine-shop, and placed them around fruit-trees; but I have never been able to see any positive benefit, judging from several experiments. If I am correct, our experiment stations have also tested the matter thoroughly. The idea of boring a hole in a tree, and putting in copperas or any other chemical to cure pear blight, is all folly. The matter has been fully written up. Mr. Garrett may be a well-meaning man, but he has certainly let his enthusiasm run away with his better judgment. I do not know how many dollars he has received besides my own; but I hope he will think better of his plan, and stop taking money from his fellow-men in this way. One dollar should buy a good-sized book telling all about chemical fertilizers, and sulphate of iron among them.

#### ELECTROPOISE, OXYDONOR, ETC.

We are pleased to notice that that excellent periodical, *Electricity*, has seen fit to copy a large part of our article given in issue for Aug. 1; and in speaking of the Patent Office and the way in which it was finally persuaded to grant a patent, it says:

It now seems that the United States Patent Office has also had its skirts besmeared in the same puddle.

At the close of the extract they sum up as follows:

As stated further along by our contemporary, it is certainly a remarkable position for our government to take that it will grant a patent for a class of things which intelligent men the world over consider to be frauds.

It seems, however, that such is the position taken by our Patent Office, and if this be so in one case, where is it going to stop? The spiritualist, the necromancer, and the fakir of every kind will necessarily have to be protected, and the honest man will go without his dues.

While this matter is again before us, permit me to say that two persons have rated me soundly, because they believe Oxydonor to be an honest invention. One of the writers goes so far as to quote Scripture, saying, "Whether this man be a sinner or no, I know not; but one thing I know, that, whereas I was blind, now I see." I give this to show how hard it is many times for people to give up their delusions. Now to business: If it is neither electricity nor oxygen (as they still persistently claim) it must be some new force just discovered, and hitherto unknown to the world. But the question then arises, Why does not the world, especially the scientific world, receive it with joy? Why is it not heralded from one end of the world to the other as were the X rays which we are all now familiar with? Has the world been backward? have scientific men been slow in investigating and assenting to the claims of this wondrous thing brought out by Roentgen? Let those who defend Electropoise and Oxydonor explain if they can.

**CIGARETTE-SMOKING.**

A lady whose husband keeps a drugstore in Dayton, O., very innocently remarked recently that the cigarette business was a good business, because, when a man once commences buying them, he *never gives it up*. One of the company suggested that the tax must make it difficult unless they had a pretty good trade; but she said it took only a little while to make enough to pay the tax. Then somebody remarked that prices had been greatly advanced; but she replied again that that made no difference; for the person who commences using cigarettes would keep on using them even if the prices were advanced from a nickel up to a dime per package. No wonder the victim never gives it up, for it is only the opium habit under another name. We are making progress in our pure-food laws, especially here in Ohio; but what about letting druggists and others push the opium business in the way I have indicated above, notwithstanding the fact that our schoolchildren are being ruined, body and soul, and our asylums and infirmaries are being constantly recruited at an alarming rate by cigarettes?

**FOR SALE.**—25 Sash, glazed, 3½ x 8 ft. x 2 inch check, glass 12 x 12; also 12 sash, regular make, ¾ x 6 in. x 1½; about 1000 ft. 12 x 12 glass, also sash-bars for same. A lot of pipe ¾ in., 1 in., 1¼ in., and some 2 and 3 in.; also a lot of pots, 4, 4½, 5, and 6 in. Will sell for one-half price of new.

J. S. WARNER, Medina, Ohio.

**What They Say about the Poudre Honey-jars.**

TACOMA, WASH.

Walter S. Ponder, Indianapolis, Ind.  
*Dear Sir*—Last shipment of jars arrived o.k. There was not one per cent loss on the entire shipment, and have never had more than two per cent loss on any shipment from you. I consider your method of crating the best that I have ever seen.

Yours truly, G. D. LITTOOV.

**HONEY-JARS.**

1-lb. with Corks, \$4.50 per Gr.  
 Labels for same, 60c per gross.

Cartons, Shipping-cases,  
 and every thing in the Apianian line.  
 Catalog free.

Apiary,  
 Glen Cove, L. I.

I. J. STRINGHAM,  
 105 Park Pl., N. Y. City.

**FARM BEE-KEEPING.**

The only bee-paper in the United States edited exclusively in the interest of the farmer bee-keeper and the beginner is **THE BUSY BEE**, published by

Emerson T. Abbott, St. Joseph, Mo.

Write for free sample copy now.

**QUEENS BY RETURN MAIL.**

Daughters of best imported queen mother, warrant-ed purely mated to drones of imported stock from a different source; hence, a direct cross. 12 years as a honey-producer on a large scale has taught me what good queens mean to the producer, as well as how to rear them. Price of queens, 50c each. Safe delivery and satisfaction, or money refunded.

L. H. ROBEY, Worthington, W. Va.

**QUEENS,** Either 3 or 5 banded, 60 cents each; 6 for \$3.00. Nuclei and supplies cheap.  
 CHAS. H. THIES, Steeleville, Ill.

**Dovetailed Hives,**

Sections, Extractors, Smokers, and every thing a bee-keeper wants. **Honest goods at close honest prices.** 60-page catalog free.

**No cheap Queens to sell; but the best.**

Golden 5 band, or 3 band from imported mother. Untested, 75 cts.; tested, \$1.00.

L. BEAUCHAMP, Box 613, San Antonio, Texas.

**Queens.**

Untested queens, 50c each; tested, 75c; Breeders \$2. Either leather or golden. My golden breeders breed all 5-banded bees.  
 W. H. LAWS, - Lavaca, Ark.

**QUEENS.**

Untested golden beauties, or 3-banded, 45 cents each. Write for wholesale prices. I have good bees. To be convinced, order a sample queen. This is a money-order postoffice.

DANIEL WURTH, Falmouth, Rush Co., Ind.

**FOR SALE.**—500 very choice Italian red-clover queens at 50 cts. each; ¼ doz., \$2.80; tested, 75 cts. Our bees made 50 lbs. per colony of red-clover honey this season. 15 years' experience in queen-rearing.  
 LEININGER BROS., Ft. Jennings, Ohio

**FOR SALE.**—Italian queens, 50 cents each.  
 Mrs. A. A. SIMPSON, Swarts, Greene Co., Pa.

## GARDENING FOR OCTOBER.

Well, friends, gardening in the open air is pretty much over unless it is late-sown wheat and rye; but this is farming rather than gardening. Spinach, dwarf Essex rape, and a few other hardy vegetables, may be put out yet, but it is a little unsafe. Onion-sets have sometimes done very well, especially the Early Pearl when planted early in October. A good many growers recommend putting out strawberry-plants during this month; but unless you have learned the trade, and take some special precaution not to have them thrown out by the frost, you will waste your time and plants. If you have a soil that never throws plants out by freezing, or if you cover your plants with mulch, and do it just right, you may not lose many. If you have some sashes to put over your plants set out in beds, of course you can go on pushing them through October and perhaps November. Asparagus-roots may be planted, but I believe most people have decided to put it off till spring. Raspberries, blackberries, and all kinds of fruits do as well as, and many times a great deal better than, when planted in the spring. Horseradish-roots will always grow if planted at any time when the ground is not frozen. Fix up your hot-beds, greenhouses, and cold-frames, if you have them; and if you have not, and love gardening, I would advise you to get a sash or two, and see what wonderful things can be done by a little protection. Try a few first; and if it requires more care than you are willing to give during the sudden changes of weather, then do not invest any further. Better gather your crops if you have not done so, then slick up the garden and sow it to rye; or if you do not care to do that, ridge up at least a part of it, and get ready to plant early stuff on the top of the ridges the first thing in the spring.

## THE CRANDALL CURRANT.

We come to the conclusion that the Crandall currant is good for pies, jelly, etc., the same as the common currant, but the skin is rather tough. Last year we made a drink which was right good. We made it like wine, only we did not let it ferment. We canned it like fruit, and it kept nice and sweet.

Berkeley Springs, W. Va., Aug. 1. H. L. WISE.

## MAKING A BREED WEEDER OUT OF A GARDEN-PLOW.

*Friend A. J.*—Last year I bought a garden-plow, a one-wheeled affair; but the wheel is larger than those seen in the market, and is so arranged that pressing on the handles tends to shoot the plow forward. I had a scuffle-hoe, made after the description given in GLEANINGS about a year ago, but I longed for one of those Z. Breed weeders. I wrote the company that I thought I could fasten the weeder part on my one-wheeled plow, and that I preferred one wheel to two, as they have it arranged. I paid them \$4.50 for the fingers and head pieces, and fastened them on my plow with a single bolt. I have just plowed my peas, six inches high, with the weeder, and it did not disturb a single pea. If the weeder is used at the right time it is one of the best tools ever invented.

I am using a Breed weeder No. 9 for sweet potatoes.

Don't you think we could arrange to publish a small book on sweet potatoes? I think I have it down to perfection.

Lebanon, O., June 16.

J. Q. MULFORD.

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

## REPORT ON POTATOES FOR 1897.

At present writing, prices of potatoes for table use are from 75 cts. to \$1.00; and in a good many places in the United States you can not get nice potatoes at the groceries for less than about \$1.00 a bushel, and they are worth from 50 to 75 cts. at wholesale.

Somewhat to our surprise, the Freeman this year has given us not only our handsomest and best-eating potatoes, but the yield has been almost as great as the Thoroughbreds, and the Freemans are the cleanest and nicest-looking potatoes of any thing we have tested. Quite a few have found fault because Terry and Maulé gave the Freeman such a boom. My opinion is that these two friends of ours deserve the thanks of the whole wide world for thoroughly disseminating so valuable a potato. The New Queen is quite a little earlier than the Freeman. Indeed, it gives potatoes of fair size for table use about as early as any potato I know of, unless it be the White Bliss Triumph. The latter has not done so well with us this season as last. A great many of our potatoes have been scabby—that is, here on our own grounds—probably owing to the large amount of stable manure we have used on our soil. The potatoes grown for us, however, by Wilbur Fenn and others in Summit Co., are free from scab, and beautiful in shape, and fully up to their usual standard, although perhaps not as large as usual. The Sir William is medium early, but too prongy to please the average market. It certainly can not compare in looks with the Freeman; but it has again shown the peculiarity of being dry and mealy, even when dug when half grown. The Monroe Seedling, when grown by Wilbur Fenn, is almost as handsome in shape as the Freeman, and comes pretty close to it in quality. Manum's Enormous outyielded every thing by far (Thoroughbred next), and the quality is very good for so large a potato. It is also one of the very best keepers known, while the New Queen is perhaps the poorest keeper of all, because it will sprout when it is springtime, no matter where you put it. The New Craig is not yet ready to dig.

## COMB FOUNDATION AT A DISCOUNT.

In order to reduce stock of comb foundation in the hands of dealers and branch offices, we offer, for the month of October only, 6 per cent discount from our prices of foundation, both wholesale and retail. You can order from St. Paul, Minn., office at 1024 Miss. St., or Chicago office at 118 Michigan St., or Syracuse, N. Y., office at 1635 West Genesee St. Those on the north Pacific coast can also secure foundation from Buell Lamberson, 180, 182 Front St., Portland, Oreg., at the same reduction from his prices. Remember, this offer is only for orders received during October which call attention to this offer, and for present stock while it lasts, and not on foundation made to order. Price of foundation will be no lower next season. If you know pretty nearly what you will need, here is an opportunity to save some money by ordering now.

## HONEY MARKET.

With the coming of cooler weather our honey trade has taken quite a start, and orders for both comb and extracted are coming in freely. We offer in 60-lb. cans, 2 in a case, water-white California honey, or clover and basswood, or willow-herb, at 6½¢ per lb.; light amber California honey at 6¢. Any of the above in 5-case lots, ½¢ per lb. less. Two barrels of tupelo honey still on hand at 6¢. Barrels hold about 350 lbs. each.

We have on hand here, and have engaged at various points in different near-by States, quantities of choice comb honey, gathered mostly from clover. We offer it at the following prices in lots of 200 lbs. or more: Fancy at 13c per lb.; A No. 1 at 12c. We sometimes have a No. 2 white which we can furnish at 11c. Buckwheat honey in the same grades at 2c per lb. less. Write us for prices on lots of 500 lbs. or more. We are often able to ship direct from the producers, saving our customers considerable in freight. Parties having honey to sell will do well to ask for a copy of our grading-rules, and directions for shipping comb honey. We seldom have any report of breakage when put up according to our method. If you wish us to make an offer on your honey, tell us how much you have of each grade, whether light or full weight sections, style of cases used, and from what source gathered.

### CONVENTION NOTICE.

The Southwestern Wisconsin Bee-keepers' Association will meet in the G. A. R. hall, in Boscobel, Wis., Oct. 6 and 7, 1897. All who are interested in bees can not afford to miss this opportunity. Come and bring your friends. Send for full program to N. E. France, President, Platteville, Wis.

### KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS is getting better and better. I take it for my boy. He has 50 hives. He is 18 years old. We all like it for its good reading.

New Brunswick, N. J., Sept. 8. ANTHONY SCOTT.

I feel lost without GLEANINGS, and do not know why I discontinued it. Inclosed find \$1.00, for which renew my subscription from the date of discontinuance. Send all of the back numbers.

Fairmount, N. Y., Aug. 29. HOWARD C. MILLS.

#### A KIND WORD, AND SOMETHING MORE.

I might say that in the past two weeks I have been reading some of your back numbers; and I never was interested in anything so much in my life; and another good thing it has done for me already—I have quit using tobacco after using it for 20 years, and I am determined to use it no more.

Streator, Ill., Sept. 10. WILLIAM DICKINSON.

#### A KIND WORD FROM AN OLD BEE-JOURNAL EDITOR.

Till last year I always had the — sent me, but it was cut off. You (A. I. R.) always said it paid to be liberal. A bee-keeper called yesterday and wanted me to say which of the bee-papers is the better. I replied that every thing in the bee-line worth printing could be found in GLEANINGS. It takes Dr. Miller to catch on them. I always read "Straws" for views.

Wenham, Mass., Aug. 9. H. ALLEY.

I have to thank A. I. Root for one of the greatest pleasures of my life: for in the winter of 1893, when down with an attack of the grip, I answered your advertisement in (I think it was) *Farm and Home*, and sent for your catalog and A. B. C. The result was bee fever; and as my father had two colonies of bees in box hives I got them from him and at once sent for your "beginner's outfit." In my second year with bees I sold \$100 worth of honey; and though the two succeeding years have been failures I am as much interested as ever, and I hope to see the year when I will make more from my bees than from my farm.

Lungrey, Quebec, Can., Aug. 18. E. W. EVANS.

### CHAS. ISRAEL & BROS.,

BOX 1837. DANSVILLE, N. Y.

## Gleanings at Reduced Rates.

With a view to encouraging membership to all kinds of bee-keepers' associations whatsoever, local or otherwise, we have decided to offer GLEANINGS at 75 cts. per name to members of such organizations. Old or new subscribers may take advantage of this offer; but in the case of the old, all back subscriptions must be paid up before the 75-cent rate for a year will be allowed; otherwise only nine months will be credited.

We must either require all subscriptions at this reduced rate to come through the secretary, or we must have evidence of some sort that you belong to some bee-keepers' society. Simply a line from the secretary, stating that you are a member in regular standing, will suffice. At your next annual meeting, bear this in mind; and if you wish to become a subscriber to this journal, hand 75 cts. to your secretary, and when that amount is received by us your name will be placed on our subscription list for 12 months.

If you do not now belong to any association, send \$1.75 to us or to Secretary Dr. A. B. Mason, of the United States Bee-keepers' Union, at Toledo, Station B. This will entitle you to a year's membership and protection in the Union, and one year's subscription to this journal.

## Honey Column.

### CITY MARKETS.

**MILWAUKEE.**—Our honey market is in very healthy condition, and receipts are good and quality generally nice, although some extracted seems disposed to work every day in the week, which shows it was not brought up under proper regulations—moral. The comb honey is improved in quality over former years. Demand is very fair, and think we can give encouragement to our shippers that good results will follow shipments sent to us. We quote No. 1 white 1-lb. sections, 12@13; 1-lb. sections, old, 8@11c; dark, 1-lb., old, 8@10; dark, 1-lb., new, 8@10. Extracted, white, in bbls., kegs, and pails, 5@6; dark, 4@5. Beeswax, 25c.

A. V. BISHOP,  
Milwaukee, Wis.

**PHILADELPHIA.**—Honey coming in freely, and some call for comb, but the hot weather of the last few days stops sales somewhat. We quote fancy white comb 13½; No. 1 white, 11@12; no dark comb in yet; white extracted, 5½@6; amber, 4@5; beeswax, 25. We are producers of honey; do not handle on commission.

W. M. A. SELSER,  
10 Vine St., Philadelphia, Pa.

**NEW YORK.**—The demand for fancy white and fancy buckwheat is good, while off grades are somewhat neglected. We quote fancy white, 12@13; No. 1 white, 10@11; fair white, 9@10; buckwheat, 8@9; extracted California white, 5@5½; light amber, 4½@5; white clover and basswood, 5@5½; buckwheat, 4. Southern in good demand now at 50c a gal. Beeswax firm at 26 @27.

HILDRETH BROS. & SEGELKEN,  
120-122 W. Broadway, New York.

**CLEVELAND.**—We quote selling to-day as follows: Fancy white, 12½@13; No. 1 white, 11@12; fancy amber, 10; No. 1 amber, 8@9; buckwheat, 6; fancy white extracted, 6½; beeswax, 25@26.

A. B. WILLIAMS & Co.,  
80-82 Broadway, Cleveland, Ohio.

**ALBANY.**—There is now quite a large stock of comb honey on our market, as is usually the case in October, but most of it is buckwheat and second-grade clover. There is not much fancy clover. We make no change in quotations. Fancy white 12@13; fair to good, 10@11; buckwheat, 8@9. There is quite a lot of dark extracted coming forward but not much call for it yet at 4@5.

CHAS. McCULLOCH & Co.,  
Albany, N. Y.

**CINCINNATI.**—Demand for honey in all its branches has been extremely dull for the last four or five weeks. Weather too warm or too much fruit on the market one or both were too blane, no doubt. We quote 3½@6 as the range of prices for extracted, and 10@13 for best white comb honey, according to quality. There is a good demand for beeswax at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,  
Cincinnati, O.

**SPRINGFIELD.**—Fancy white clover, 12c; choice white clover, 10; no buckwheat in.

PERKINS & HATCH,  
Springfield, Mass.

**DETROIT.**—Best comb honey, 11@12; other grades, 9 @10½; extracted white, 5@5½; but little call for dark grades; beeswax, 25@26.

M. H. HUNT, Bell Branch, Mich.

**COLUMBUS.**—Demand very good for white clover. Fancy 12½@13; No. 1, 11@11½. We are in the market for white clover in 12 and 24 section cases.

THE COLUMBUS COMMISSION & STORAGE Co.,  
Oct. 7. 408-113 N. High St., Columbus, O.

**MINNEAPOLIS.**—Fancy white-clover comb, good sale at 9½@10½; other kinds accordingly. This is a good place for the right kind of honey. Have moved a large quantity during the last two weeks. Extracted (best) 5@5½; light demand for same.

S. H. HALL & Co.,  
Minneapolis, Minn.

**KANSAS CITY.**—We quote No. 1 white comb, 11@12; No. 1 amber, 10@11; No. 2 amber, 8@9; extracted white 5½@6; extracted dark, 4½@5; beeswax, 22@25.

C. C. CLEMONS & Co.,  
Kansas City, Mo.

**BOSTON.**—We quote our honey market as follows: Fancy white, 13; No. 1 white, 11@12; No. 2 white, 9; white extracted, 6@6½; light amber, 5@5½; beeswax, 27, and wanted.

BLAKE, SCOTT & LEE,  
Boston, Mass.

**CHICAGO.**—Fancy white comb, 11@12; good white 9@10; best amber, 8@9; dark grades, 7@8; extracted white, 5@6; amber, 4@5; dark, 3@4; beeswax, 26@27. The receipts are now quite large, and it is chiefly that which has been secured from clover, very little from the asters, and some buckwheat.

R. A. BURNETT & Co.,  
163 South Water St., Chicago, Ill.

**FOR SALE.**—25 bbls. extracted pure white-clover honey, very light in color, and of finest quality, at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

**FOR SALE.**—A lot of good extracted clover honey in 60-lb. cans.

J. NO. A. THORNTON, Lima, Ills.

**WANTED.**—To buy quantity lots of fancy comb honey in non-drip cases.

B. WALKER,  
Evart, Mich., or 541 Van Buren St., Chicago.

**FOR SALE.**—Alfalfa honey, light amber, in carload lots. 3½ cts. per lb.; sample, 10 cts.

JOHN NIPPERT, Box 1051, Phoenix, Arizona.

**FOR SALE.**—Pure honey.—Clover, extracted, 6½ cts. per lb. Buckwheat, extracted, 4½ cts. per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City.

**FOR SALE.**—Buckwheat extracted in 50 and 210 lb. packages f. o. b. for 4½c a lb.

W. LAMAR COGGSHALL, West Groton, N. Y.

**FOR SALE.**—Choice honey, 6000 lbs. in well-filled sections, at 9½c per lb.; extracted, 4½.

W. C. GATHRIGHT, Dona Ana, N. M.

**WANTED.**—Parties having fancy or No. 1 clover honey to quote prices.

F. H. McFARLAND, Hyde Park, Vt.

**WANTED.**—Shipments of comb and extracted honey. Can dispose of several hundred pounds of first and second grades. Can give good reference. Write me what you have and the price asked before making shipment.

D. N. RITCHEY, Black Lick, Ohio.

**FOR SALE.**—Tons of honey, comb, at 7 to 12c per lb. Inclose stamps for samples of extracted at 4 to 6c, in 160-lb. kegs, f. o. b.

N. L. STEVENS, Venice, N. Y.

## FARM BEE-KEEPING.

The only bee-paper in the United States edited exclusively in the interest of the farmer bee-keeper and the beginner is THE BUSY BEE, published by Emerson T. Abbott, St. Joseph, Mo.

Write for free sample copy now.

# A Tested Queen and the Review for \$1.50.

I have a large number of nuclei containing fine tested Italian queens of this year's rearing, and have decided to use them in helping to build up the circulation of the **Review**; hence offer a queen and the **Review** one year to *new* subscribers for only \$1.50. **Review** alone, \$1.00; queen alone, \$1.00. If several queens are wanted, write, and the price will be made according to the number. As a rule, orders are filled by return mail, and there is never a delay of more than three or four days, and that on large orders.

W. Z. HUTCHINSON, Flint, Mich.

# \$100

Given as **BOUNTIES** to purchasers of the improved Danz. Hives and Sections. For particulars see p. 64, of my book, "Facts about Bees." Sent Free for 2-cent stamp. Address  
**F. DANZENBAKER**, Washington, D. C.

**Italian Queens**, either golden beauties or 3-banded imported stock. Tested, 75c each; untested, 50c each; select tested, \$1.00 each; breeders that produce pure stock, of either variety, \$2.00 each. P. O. M. O. office, Lavaca. **E. A. SEELEY**, Blo mer, Ark.

Philadelphia Office of  
**THE A. I. ROOT CO.**,  
 10 Vine St., Philadelphia, Penn.

Now is the time to order  
**Shipping - cases. Winter Cases, Chaff Division-boards, etc., etc.**

Order from catalog; prices are same as from factory.

## Shipping-cases.

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA**. Immense stock. All orders for cases or other goods shipped by return freight. Address

**JOS. NYSEWANDER**, Des Moines, Iowa.

## STRAY STRAWS

FROM DR. C. C. MILLER.

I SEE ON PAGE 709 that the president read one of R. L. Taylor's papers. That makes me think more of McKinley than ever.

IT DOESN'T SEEM such a great many years since all our previous lighting-arrangements had to be thrown away to make way for something to burn kerosene, and now comes that new light mentioned on p. 713 to knock kerosene out.

WANTED! A plan to get a colony of bees to empty the honey out of a super without allowing bees of other colonies to touch it. [While you are putting in your specifications, doctor, please add that those same bees must put it in the brood-nest below.—ED.]

YOU SAY, MR. EDITOR, that I haven't told you whether I had a good honey year. I've been so busy taking care of the crop I haven't had time to tell you. But it's been a grand season. Tell you more about it later. [Good! I feel like throwing up my hat.—ED.]

WHITE DUTCH CLOVER is pretty much the same thing as white clover, according to A. I. Root, p. 706. Friend Root, may be you'd be willing to oblige an old friend by dropping out that "pretty much," or else telling the difference between white and white Dutch. [I do not believe "A. I. R." can. To my eyes they look exactly alike. "Pretty much," I suppose, slipped in accidentally.—ED.]

FRIEND A. I. ROOT, you touched on one of the crying evils of the day, p. 715. Tipping is a kind of stealing that takes the manhood out of the recipient, but after all isn't the fault with the tipper? If all had the backbone you had, and stood out against it, the practice would soon be stopped. But one is all broken up over deciding what's the right thing to do on a Pullman sleeper, when one knows the poor porter will starve if one doesn't tip him.

USE FOR PROPOLIS. A California writer in *American Bee Journal* says he saves up clean propolis, and always has a ball of it on hand. When about to hive a swarm, he rubs the in-

side of the hive vigorously with the propolis for a minute *immediately* before hiving the bees, and has not lost a swarm for many years. [It is possible that propolis may give a hive somewhat of a homelike smell; but I should really expect moonshine to have just as much effect.—ED.]

WHY ARE FREAKS with eyes of different colors found only among drones, and not among queens and workers? [We know that the males in the bird kingdom are usually more highly colored and in other ways handsomer than the females. In the case of the birds we would suppose that the high colors were intended to attract the attention of their more somber-colored sisters; but it would be a pretty big stretch of fancy to make a like comparison in the case of drones and queens. I give it up.—ED.]

SAV, ERNEST, wouldn't you like to see the finest show of horses ever gotten together? That's what's expected to be at Chicago at the time of the Northwestern bee convention. Now, what more can I say to coax you to be on hand Nov. 10, 11? Plenty of beefsteak too. [You will have to trot out something better than horses to get me to come. I used to be quite a horse-crank; but the bicycle has completely supplanted the horse in my affection. Beefsteak—well, yes. That is appetizing. Well, what else have you to attract a Buckeye chap just like me?—ED.]

"BEE CRANK" says, in *Southland Queen*, that he saves money by using extra-thin foundation in brood-frames. Fasten the foundation in frames, hang two or three frames in rather light colonies that are building comb, and as soon as they draw out the foundation it is safe to hive swarms on. [I should not be surprised if Bee Crank were right; but the handling of those frames, putting them into and taking them out of light colonies for the sake of getting the bees to fasten and stiffen the foundation, would be a great deal of extra work; and if time is worth anything, brood foundation at a slight additional cost would be cheaper in the end.—ED.]

"PERHAPS if an experiment station could take hold of it, something might be done."—*Editor*, p. 695. You're with Prof. Cook in thinking no one but some scientific fellow can breed for improvement. Did the experient

stations give us five-banders? Have they given us any improvements in bees? Have all the stations put together done as much "along this line" as Doolittle? Say, what'll you take for a good glossometer? [Doolittle—well, I would make an exception in favor of him. He has already bred light-colored bees and yellow Italians that he says will cap honey as white as blacks. Now tell him to stretch the tongues of those same bees and we will make a glossometer to measure them.—ED.]

HERR GRAVENHORST says that, after having tried hundreds of cases year after year, with half his swarms supplied with starters at the beginning, and full sheets of foundation later, and the other half with full sheets from the start, he is thoroughly convinced that, on the average, they do better to begin with the starters. [Gravenhorst is the editor of the *Illustrierte Bienenzeitung* (Illustrated Bee-journal) published at Braunschweig, Germany, and a bee-keeper of international reputation. If he sees this I hope he will tell us how he came to this conclusion. If he is right, then a great saving of foundation could be effected. It would be a bad thing for the supply-dealer, but a good thing for the bee-keeper. Let us have the truth, anyhow.—ED.]

L. L. SKAGGS thinks it a great mistake to suppose that bees do not thin the septum of heavy foundation. He made a quantity of foundation which weighed four sheets to the pound, and the bees thinned it so that one could hardly tell the difference, when chewing it, from natural comb. They used the extra wax to build the cell-walls.—*Southland Queen*. But it doesn't always work that way. [I do not think it is claimed—at least we have not done so—that the bees *never* thin the bases of foundation; but I think that, as a general rule, they do not; and we might say they never do if honey is coming in fast; but they almost invariably thin down the walls, but do less of this thinning if honey is coming in rapidly.—ED.]

P. A. STOLI says in *American Bee Journal*, that he thinks the queen has an influence over the morals and manners of the workers. He had some vicious blacks that were lazy, and formed a nucleus from them, giving the nucleus an Italian queen, and the blacks of that nucleus at once became gentle and industrious. A more marked case came in my experience, in which a queen was killed because her bees were so cross, and the temper of the bees seemed to be changed utterly by a change of queens, and that, too, before the old bees had time to die off. [This question was discussed a few years ago, and the general verdict then seemed to be that the queen did seem to have quite a toning-down effect upon the bees of the hives, even though they were not her daughters.—ED.]

C. P. DADANT, basing his belief on 25 years' experience with a number of out-apiaries, is emphatic that bees do not work to any advantage more than two miles from home. They travel furthest where the country is smoothest, with no hills to climb or heavy timber to pass.—*American Bee Journal*. [My limited

experience goes to show that Dadant is about right. The bees at our basswood orchard are only about a mile and a half in a bee-line from our home apiary; and yet our home bees have never flown to the basswoods, when in bloom. I do not mean to say that the bees have *never* gone over a mile and a half; but as long as they can get plenty of nectar in short ranges they will not go long distances. If forage is scarce and at long range, bees will, of course, take long flights. All depends upon locality, character and extent of the honey-flow, and the sources of nectar.—ED.]

THE OLD-FASHIONED PLAN of raising a hive half an inch or an inch on four blocks during hot weather seems coming again into favor. Some are troubled with the thought that the bees are hindered about getting on the combs, there being no place for them to climb up except at the four corners. I don't believe it's worth while to worry over the matter so long as the bees don't, and in actual practice you don't find a lot of bees waiting for a climbing-place. [I do not believe that bee-keepers realize the advantage there is in having plenty of space under the brood-frames, with a deep entrance, during the honey-flow, when the weather is hot. I am not a prophet nor the son of a prophet, but I believe the time is coming when wide deep entrances will be used exclusively; and I have a feeling that swarming will be very materially reduced thereby. Of course, when the honey-flow is over, and robbing is the order of the day, then it may be advisable to contract the entrances down. Aside from the trouble of swarming, deep entrances would prevent loafing to a great extent, and to a like extent the melting-down of combs. Keep on talking about and considering the idea, brethren, until bee-keepers begin to "sense" it, as Samantha Allen would say.—ED.]

"I NEVER SAW a queen pipe yet but there was a decidedly tremulous motion to her wings," quoth ye editor, p. 694. I never saw a horse neigh but there was a decidedly tremulous motion to his tail. But cut off the tail and the horse will neigh just as well; and cut off the wings, and the queen will pipe just as well. Frank Cheshire says, page 157, Vol. II., speaking of piping, "It is certain that the wings are not concerned in its production, since queens clipped so vigorously that not a vestige of wing remains can be as noisy as others." [Cheshire's argument looks like a clincher; and while I am inclined to believe he is right, I should wish to know first whether he was taking hearsay evidence that queens would pipe when both wings are cut off close, or had actually tried the experiment himself. I may have to, but I do not want to give up, that the wings have nothing to do with the matter until I have tried cutting off the wings. If I should go right now into the apiary and do some close wing-clipping I might have to wait days and even months before the queen would pipe before my waiting eyes. But, say, doctor, our Ohio horses do not give a tremulous shake to their tails when they neigh, so I do not see

the force of your argument; but then, your *locality* may have quite an effect upon horses' tails.—[Ed.]

### BEE-KEEPING AS A SPECIALTY AND AS A SIDE LINE.

Changing One's Mind: Why the Professional Man and the Farmer Should Keep Bees; California Fruit-men the Friends of the Bees.

BY PROF. A. J. COOK.

*Editor Gleanings*.—Our good friend Dr. Miller in a recent note referred to me as having changed my mind, in that now I believe in bee-keeping for others than specialists. I have changed my mind very often, and am not a whit ashamed of the fact. Emerson says, not to change is to die. Surely one who never changes his mind must be very inconsequential indeed. But in this matter I have not changed my mind; for of old I used to argue stoutly with such staunch defenders of the faith as Bingham and Heddon, they contending that only specialists should engage in the pursuit, while I was as emphatic in the position that the ranks should be swelled by any who would go at the work earnestly, intelligently, and with the persistence that could not fail. Later I had the same discussion with our friends Taylor and Hutchinson. I always believed I had the weight of the argument on my side, and still think so, and hence have not changed my mind at all.

One fact alone, it seems to me, settles the matter on my side, to wit: Some of the very brightest and most successful apiarists have not been specialists, but, rather, amateurs; or at least the bee-keeping part of their work was their avocation, and not the main part of their work. Langstroth, Bingham, the Oatmans, and even the senior editor of GLEANINGS, became noted as bee-keepers before it was their leading pursuit. I believe that the majority of those who have had the best success, and have done the most for the pursuit, have been those who have made bee culture only the pick-up work. I perhaps feel more sensitive regarding this matter, as bee-keeping has never been my leading pursuit; yet it has been a very great pleasure to me, and a source of no little profit as well. I know of several farmers who have cared for their farms well, and at the same time have made large profits from bees. I have a brother who has a large well-tilled farm; and although he cares for the farm all himself, yet he keeps a good-sized apiary, and for three successive years he made more from his bees than from all the rest of his farm. With such examples before us, is there any wonder that some of us believe that others than specialists may well keep bees? I am sure that my brother would laugh at such a proposition.

The fact that the pursuit of bee-keeping does not occupy one all the time, and the further fact that, in off years, there is little or nothing to do, makes it all the more desirable that bee-keeping alone should not occupy

one's entire time. By a little planning one can combine bee-keeping with some other pursuit, so that neither will interfere with the other. This not only has the merit of keeping one well employed all the time, but also gives variety to the work, and so makes life more enjoyable. A variety also is recreative, and so rests one and makes his work more productive, and at the same time adds greatly to one's health and vigor.

In the face of the many noted examples, I need not say that it is quite possible for one to master bee culture, even though he is deeply absorbed in other work. The very study required not only brings keenest pleasure, but often gives a discipline that makes one more capable in other lines of work. I am sure that there are lawyers, doctors, etc., who do better work in their practice because of the restful pleasure that they get in the care of their bees. I have known some remarkable cases of just this kind. A perplexing law case is not a very effective sedative. Any thing that will help one to forget the disquieting experiences of the daily life will add to one's effectiveness as well as to his length of days.

I have often worked in my study until the weariness was overpowering, and went forth to work in the apiary, when shortly I had forgotten that I was weary, and went back to my study able to do what would have been otherwise quite impossible except for the restful pleasure received in the apiary.

There is another argument, from the standpoint of economy, that should have some weight. The bees are needed in every garden and orchard to do the work of pollination. If the specialists are depended upon, many a fruit-grower will suffer. Not a few California fruit-growers now arrange to have bees in the orchard. They find that this pays well. The pomologist may well study to care for bees, and then he may be independent, and keep his own bees.

The argument on the other side is, that the specialist will learn and practice better methods, and so will do nothing that will harm the pursuit. But does he do better? I have been in a great many bee-yards, and I have seen as much perfection among the so-called amateurs as among the specialists.

In view of all these facts, I am, as I have always been, in favor that all who feel moved to do so, and will take hold of the matter with vigor, shall embark in the bee business.

#### NOTES.

The fruit-men of California have ceased to denounce the bees. We rarely hear other than praise of the little honey-gatherers.

The present season has been a very good one in Southern California. Many bee-keepers with hundreds of colonies all in one place have taken over 100 lbs. of finest honey from each colony.

Claremont, Cal., Sept. 25.

[I most sincerely admire that spirit in any man who is frank enough to admit that he is liable to error, and is therefore not only willing to change his preconceived notions, but is

willing to come out and confess it. Somehow I have confidence in such a man.

In regard to specialists, if accurate figures could be gathered I believe that 90 per cent—yes, 99 per cent—of all the honey that is produced is by the class that you have so ably defended. At the Buffalo convention, made up of some of the most extensive honey-producers of the world, the request was made for all to rise to their feet who made bee-keeping their sole means of livelihood. Scarcely one arose. To my personal knowledge, there were farmer bee-keepers present at that meeting who produced anywhere from 40,000 to 75,000 pounds of honey in a single season. One might almost call them specialists; but the fact remains that they are also quite extensively engaged in farming. In fact, when one goes by their places, as I have recently done, the big bank barns, broad acres of wheat and corn, and flocks of sheep, are more suggestive of agriculture than of apiculture.

\* But Prof. Cook very properly is urging the claims of the small bee-keeper who takes up bee-keeping as a recreation, as well as a business that will yield some revenue. Many and many a professional man would be broken down by nervous prostration were it not that he could rest his tired brain by turning it now and then to something else entirely different from his main line of work. A very large number of such long for the time when they will be able to go on to a farm; but the time never comes, for the very reason that they must leave town and quit their professional work, which they are loath to do. But bee-keeping, if they only know it, is a side issue that they can carry on without moving from town; and their back yards will probably give them all the room they require. It is from this class we find some of our brightest beekeepers.

The question is asked a good many times, "Would you advise me to give up my business and make bee-keeping my sole means of livelihood?" We almost invariably reply something after this fashion: "The bee business is too uncertain. Stick to your life work, and make bee-keeping a side issue; and then if you have a series of poor years for the bees you will not be bankrupt. Specialties in trade are all right in their place; but specialties in rural pursuits are a little risky. Where there is one Terry who can make potato-growing a specialty and a success, there are thousands who will do better to carry on mixed farming. Where there is an Elwood or a Hetherington or a McIntyre who makes bees a sole means of livelihood, and is successful at it, there are thousands who would do better to carry on bee-keeping in connection with some other pursuit."

Dr. C. C. Miller comes very near being a specialist; but if one were to ask him whether his bees gained for him all his board and lodging, he would say no. He dabbles a little in farming and a good deal in literary work. His pen (or, rather, his typewriter) consumes a good part of his time. Whether his literary work nets him as much as his bees is doubtful.—Ed.]

## BREEDING FOR LONG TONGUES.

Square Bottom-bars Not Satisfactory, and Why.

BY J. O. GRIMSLEY.

I have just finished reading GLEANINGS for Sept. 15th — have read *every word* in it, and can't help expressing my appreciation of such a valuable journal. The truth is, GLEANINGS improves with each number. But I think I'd better stop this "flattery," as some may construe it, and get down to what I wanted to talk about. There were two or three things I was particularly interested in, as my mind had been "hungry" for something on these subjects.

"Breeding for long tongues." Why not? I think Prof. Cook is talking just right; and all that we really need now is those "tongue-gauges" he mentions. But who will get them up? and what will be the cost? Suppose all our queen-breeders (or, say, the members of the National Queen-breeders' Union, now in course of organization) were prepared to advertise daughters of "A No. 1" breeders, whose tongues measure, say, 4.9, 5.3, or whatever number of millimeters it is. We often see advertisements of "red-clover" queens, which, in my opinion, are very delusive. I am confident there is a great difference in the length of the tongues of bees, and now let us not permit so valuable a suggestion to die in the "pupa."

I see considerable said about "bottom-bars." Some say *square*, some say "nix." On that line I want to give my experience, although it may not be so extensive as that of some of the veterans. The first bottom-bars I ever used were square— $\frac{3}{4}$ —and I thought they were *the* thing; but the truth is, if the hive were perfectly level (as it should be) the combs were *never* built to the bottom-bar. If one side of the hive chanced to be lower than the other, the bees would build the comb down past the bottom-bar, and would nearly always fasten it to the side; but I don't want those "whopper-jawed" combs, and I hardly think any other apiarist does if he is a good one.

My trouble did not end there. When I put on extracting-supers I soon found that, between the bottom-bars, would always be a "mess" of burr-comb; and while the bees would "build down" better in the super, it took a *perfectly* level hive (or perpendicular end-bar, if you please) in order to get a decent comb. Then came the job of (or, rather, the experience of) changing to a bottom-bar an inch wide, which has given much better satisfaction. With this I find the same difficulty in getting combs "built down" except in the super). I see that some of the readers advocate a V-shaped bottom-bar, which *may* be all right; but I want to tell you that, during the coming season, I am going to make a lot of frames (for experiment) with an inserted comb-guide, the same as is illustrated in your "all-wood frames"—the guide to be on top of the bottom-bar, of course, and the bottom-bar the same width as end-bar, which will leave only a bee-space between the bottom-bars. I

am inclined to think the bees will build down to this.

"Oh!" some will say, "that comb-guide will take up too much space."

Now, don't condemn the idea till you try it and see that it is no good. If any one has already tried this I should like to see a report of his experiment. It might save me the trouble of making a failure.

We had prospects for a real good fall honey-flow, but it was cut off by a cold rainy spell.

Byrdstown, Tenn., Sept. 23.

[Along about the middle of the summer I expressed a leaning toward square bottom-bars; but since that time I have paid particular attention to square and wide bars, as I have been looking over the hives. The former are objectionable for the very reasons you have mentioned, and I am not sorry we drop-

ped them. A bar  $\frac{3}{4}$  inch wide and  $\frac{1}{4}$  inch thick suits me as well as any thing, I now think.—ED.]

termed it, sitting on a thistle near some hives, and asked permission to go to the house and get his gun. While the boy was away the bird made a swoop out over a hive, and I recognized him instantly as a whippoorwill. I watched him then until the bees were all in, when he took his departure, and before the gun came to hand. If some of us don't catch the yellow fever by next Monday night, this whippoorwill will pay the penalty for eating my Italians. I am ashamed to say that this is the first evening that I have been among my bees for several months; and to find a robber of this size and capacity among them is rather a surprise. It is the first time the possibility of the whippoorwill's eating bees has ever been suggested, to my knowledge; but there can be no doubt about the fact. I saw him swoop and hover in front of the hives distinctly three times; and if nothing prevents

W. A. SELSER, WIFE, AND BABY.—SEE EDITORIAL PAGES.

ped them. A bar  $\frac{3}{4}$  inch wide and  $\frac{1}{4}$  inch thick suits me as well as any thing, I now think.—ED.]

#### ENEMIES AMONG THE FEATHERED TRIBES.

The Whippoorwill, or Night-hawk, of the South; King-birds.

BY T. S. FORD.

The writer has a bit of information for Southern bee-keepers that will be of interest. It is in relation to a new enemy to the apiarist. Going about dusk to the apiary this evening, for the purpose of feeding some weak colonies, my son called my attention to a hawk, as he

I will verify my own statement next Monday night by examining his maw.

Our whippoorwill is very different from yours, being much larger, and has a different note. He is properly a night-hawk.

Before closing this letter I will wait till Tuesday, so as to be certain.

Sept. 27.—Late this evening my son killed the whippoorwill, sure enough; and on examination of its crop we found the proof of his guilt in the shape of a wad of partially digested bees.

You will find inclosed a feather from the tail, which will give you an idea of the color of the bird. On a close examination the plumage is very beautiful, though the coloring has a somber appearance. On a careful measurement the mouth of this specimen was

found to be  $1\frac{3}{4}$  inches in width. The distance from the tip of one mandible to the tip of the other was  $2\frac{3}{4}$  inches, when widely extended. This individual had taken up its quarters within 100 yards of the apiary, in the shade of a dense thicket, I find on inquiry, as he has been seen there many times this summer.

When mating, our whippoorwill is a noisy fellow; but after July he is perfectly silent. It was a great surprise to find this specimen here so late, as the other fly-catchers migrated some time ago.

In writing to the *American Bee Journal* last year, the habits of the king-bird, or beemartin, being the subject, it was mentioned that, in the fall, the king-bird was good eating. My son killed some for me this fall, and a more delicious morsel was never tasted. They were loaded with fat, and on being opened gave forth the odor of the magnolia seed. This was a great surprise, inasmuch as I had supposed that they were entirely addicted to insect diet. Several weeks ago great flocks of these birds (or, rather, vast numbers of them) could be seen any fair day, being then on their journey south.

The whippoorwill was served up for supper, and was himself not at all bad, so the children report.

The writer is shut out from the world by an impassable quarantine, and can testify to a very novel experience, which, however, would not interest the readers of GLEANINGS.

Scranton, Miss.

T. S. FORD.

[I do not know just how it would be in the South; but in the North but very little attention need be paid to the alleged depredations of the king-bird and other enemies of the bees among the feathered tribes, except in the queen-rearing apiaries. The use of a shotgun or small rifle to kill and scare away king-birds (as I believe them to be particularly fond of young queens when on their wedding-flight) is sometimes advisable. I remember quite distinctly that, a few years ago, we were losing quite a number of our young queens. King-birds were quite frequent visitors at our apiary. I finally shot a few of them with my rifle, and the rest disappeared. About this time our queens began to be mated again with the usual regularity. While I can not be positive that king-birds actually made away with the queens, the disappearance of the king-birds and the non-disappearance of queens was somewhat significant.—ED.]

#### PARAFFINE PAPER FOR COVERING SECTIONS, AND THICK TOP-FRAMES.

BY F. L. THOMPSON.

[About a year ago I reported that Mr. Danzenbaker had secured some very nice clean comb honey, the sections of which had not been touched by a scraper-knife, and which had secured the first prize at one or two of the State fairs. This happy result Mr. Danzenbaker attributed to the use of paraffine paper.

At other times I have said much in favor of thick-top frames as being especially free from burr-combs (not brace-combs). As I have been an exponent of both ideas I am very glad to give the results of an un-

favorable experiment with both paraffine paper and non-burr-comb frames; and while I do not think one swallow makes a summer, I am glad to give this report prominence in our columns, without a comment. If friend Danzenbaker chooses to reply he can have space.

The report that I refer to appears in the *American Bee Journal*, page 677, and is as follows:—ED.]

Noticing that sections which have been covered with paraffine paper were said to be perfectly free from propolis, and even took prizes at various fairs, I procured a number of sheets and applied them according to directions. During the early part of the season the results were pretty fair, though the sections were far from being free of propolis, even on the top edges. Still, the tops between the edges were perfectly fresh and bright when the sections were removed, forming a marked contrast to other sections which had been covered with a  $\frac{1}{4}$ -inch "layer of air."

Later in the season the bees plastered propolis just as freely at the junction of the paper with the section edges as they did anywhere else. I conclude that it was the combination of paraffine paper with some other things that produced that prize honey, and that those other things were far more important. I have before this produced section honey without the aid of paraffine paper, which went into the case untouched by the knife. They were built during the first of the flow by new swarms, in brand-new hives, in supers which perfectly compressed both edges and ends of the sections, and over a honey-board.

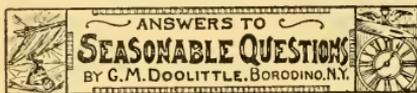

Another objection to the paraffine paper is the fussiness it requires, with the extra paper and thin boards (I use old separators), and the difficulty of removing in the last half of the season. Every time a super replaces another, there is a lot of red tape, so to speak, to go through with. First, the newspapers and thin boards must be carefully removed and laid aside; then, still more carefully, the paraffine paper—snip, snap, tear (confound it)—wsh-sh-sh-crack! (darn these things, anyhow!) and then it is laid on the lower super reversed, first smoking the bees out of the way, except some refractory ones that have to be cow-catcher-ed out of the way with the edge of the paper; then, if the wind is blowing ever so little (it usually is, just then), held there while the other paraphernalia are reached for and spread on in succession; and you have the satisfaction of knowing that you have fixed up one super in good shape in the time that it would ordinarily take to fix two. I've had enough of it. I believe a fresh surface of burlap over every super full of sections, with three or four thicknesses, not necessarily unsoiled, above that, to keep it flat and conserve heat, would amount to about the same thing, and be much quicker handled.

By the way, I am coming to think honey-boards are a valuable aid in producing first-class comb honey. I was obliged to do without them this summer, and the percentage of fancy honey was rather small, in spite of the fact that half the hives had thick top-bars. The editor of GLEANINGS, speaking of thick top-bars and burr-combs, says the exception proves the rule. I would rather do without

BEE-KEEPERS TAKING IN NIAGARA FALLS.

the exception, in this case, because, besides entirely preventing burr-combs under the sections, the honey-boards very largely diminish travel-stain on the section honey, better, I think, than thick top-bars do. I am not sure of this, having been too busy to observe accurately, but that is my general impression.

#### WEED DRAWN FOUNDATION.

*Question.*—I noticed last spring that you would try the deep-cell foundation. How did it prove with you? Do you think it will be of any help toward the retarding of swarming? If we could only work for comb honey, and not be bothered with swarms, how nice it would be!

*Answer.*—I received two lots of the deep-cell foundation—one made of white wax, the latter part of the winter, and one of yellow wax, this latter reaching me about the 10th of July. The latter appeared to be nearly perfect, but, like all other samples which I received, it had what is known as the "flat base" to the cells. It was carefully fitted into sections, and put on the hives, a few sections to the hive, alternated with comb foundation of the Falconer make, just before basswood opened, so as to give it the best possible test, as basswood is our main honey-flower in this locality. But during a period of three weeks, in which it rained every day, our honey crop came near being a failure; and the result was, that very few of the sections having this drawn foundation in them were finished fit for market. I put the date of giving the sections to the bees on each section, and at the end of three days took out some sections containing this deep foundation and that of the Falconers' make. At the end of six days I took out more of each, and a careful comparison of each shows that the difference in appearance at the end of three days was not enough so that it can be detected, while at six days the difference is in favor of the foundation, the best specimens from foundation showing a weight of three-fourths of an ounce more of honey stored therein than was stored in the best specimens of the drawn foundation, while many more of the sections with the ordinary foundation were completed than of those containing the drawn foundation. This was very much against my expectations, for I had great hopes that this deep-cell-walled foundation was to be a boon to bee-keepers, if it could be made at a price to come within the reach of the average practical apiarist. When I found that disappointment was the record made, after a very careful trial, I began to look to see what was the trouble that the "thing did not pan out" as I had expected. I was not long in discovering that the trouble was in the flat base. I had used much ordinary foundation having the flat base, both of the Van

Deusen and other makes; but with such foundation the bees always changed the flat base to that of natural comb, both with thin foundation and that made for the brood-frames, so that, after the same was filled with honey or brood, little difference between the base of what was once flat-bottomed foundation and that which had the natural base, could be seen. But when the high cell-walls were put on this flat base, it placed the bees where it was impossible for them to manipulate the base so as to change it from the flat to the natural shape, and their efforts in this direction caused them to be longer in perfecting section honey from this new deep-cell-walled foundation than where the ordinary was used. It also caused them to complete some sections on one side, while the other side remained almost untouched.

On cutting through the honey of sections which had been completed, and on looking into the cells of those not completed, it was easily seen that, in their efforts to change the base to the cells, the bees had put wax all around in the sharp angles at the base of the cells—so much so that, in many instances, the bottoms had a rounded appearance. Not only did I find this, but in a few instances it was evident that propolis had been used instead of wax, while the whole base in much of the unused part was varnished over with propolis till it was glossy, almost equal to varnish. This thickening of the base made the resistance in cutting the combs of section honey much greater than was that of the foundation, after completion, which every one admitted whom I asked to try the matter. Then when it came to eating the two, there was a half more of accumulated wax in the mouth from the drawn foundation than from the same-sized piece built from foundation. To show the real difference in the two I tried the resistance at the end of No. 16 wire, and found, with an average, from a five-trial test with each, that the resistance from the samples sent in the winter was 10½ ounces; from that sent in the summer (made from yellow wax) it was 8¾ ounces, while from that built from foundation it was only 5¾ ounces. In each of these trials, well-filled sections were taken, which were nicely capped over, or in marketable shape.

As has been spoken of in GLEANINGS, I have no doubt that the poor season had very much to do with the matter; and had the season been an extra good one the bees would have rushed honey into the cells without stopping to add the extra wax in the corners. But it will be remembered that much of the help to bee-keepers would come, by way of drawn comb, in a poor season, thereby enabling us to get something of a crop of honey, as we do with partly filled sections left over from the previous season, could drawn comb be as readily accepted by the bees as are these partly filled sections. Then if swarming is to be retarded, as our questioner hints at, the bees must not be averse to accepting what we give them, but, on the contrary, be only too eager to work on the same, thereby forgetting their desire to swarm.

I think, however, that, with all its faults, this deep-cell-wall foundation will be a boon to those who use bottom-starters, for in that case only two rows of cells will be needed; and with the experiments I have made along this line I find it keeps its place perfectly, while the bees are enabled to manipulate the first row of cells the same as they do ordinary flat-bottom foundation. I am told that Mr. Weed thinks he can yet arrange so as to make this drawn foundation with the natural base; and if so I shall look forward with eagerness till I am able to give such a production a careful test during the season of 1898.

#### DRAWN FOUNDATION NO ADVANTAGE OVER COMMON FOUNDATION.

I have just taken off the super containing drawn foundation. I will send you an average specimen of drawn foundation and common Weed-process foundation. The honey-flow nearly stopped in about five or six days after putting the super on. The super was filled with newly extracted unfinished sections except two of drawn foundation and two of common foundation, both having the same advantage by being placed near the center of the super. Three days after putting on, they were examined. At that time the drawn foundation was not touched, except to fasten it a little to one side. Contrary to my expectation, the common foundation was drawn out to nearly equal the drawn foundation.

Now, on taking the super off I find the only advantage the drawn foundation has over the other is in being so nicely fastened at top and sides. As usual in a poor honey-flow, the common foundation was not well fastened to the sides, while the drawn foundation did not even have a hole at the corners for a bee to get through.

However, this is no fair test. A man should have a whole summer to give an intelligent answer. I do not think the fear that you will have a cud of wax to chew after eating honey from drawn foundation is where the trouble will be. I think that to be able to make it cheap enough so the common bee-keeper can afford to use it will be the trouble, besides the difficulty of shipping. H. S. WHEELER.

Mt. Pleasant, Mich., Sept. 3.

[See article by G. M. Doolittle in this issue. We have had so far quite a number of flattering reports in regard to the new drawn foundation. Note, for example, those just following this; but as there are, undoubtedly, instances where bees do thicken the base, we, The A. I. Root Co., through Mr. Weed, will very likely abandon the flat base and make in its stead deep-cell foundation with *natural* bases. While the walls will not be so deep

nor perhaps as delicate, the bases will be as thin as or thinner than those of the natural.

We have completed a set of dies on a very small scale that give us strong hope that the new product will secure to us all the advantages that we hoped to obtain from the use of drawn foundation with flat bases.

Strange as it may seem, the dies for making the natural bases are very much more easy to make; and the only wonder is that we didn't "tumble" to the fact sooner. We shall hope to have a set of dies now on a sufficiently large scale by next year so that we can give all our friends all the drawn or deep-cell foundation they want, with *natural* bases. If flat-base drawn foundation has in a *majority* of instances given good results, we may confidently expect that the same article with *natural* bases will invariably do so. Even if the flat bases always gave satisfactory results, we should *now* prefer to use the natural, *because* it will cost less.—Ed.]

#### DEEP CELL A GREAT SUCCESS.

I have tested your drawn foundation in my apiary, and the result was so satisfactory that I will use it next year instead of foundation if you can furnish it at a reasonable price. Please advise me at what price you can furnish me 25 or 30 lbs. Of course, I shall not need it before next April, as our honey season will not commence before then.

W. O. HEBISEN.

Emory, Texas, Oct. 6, 1897.

#### FIRST PRIZE FOR DEEP-CELL FOUNDATION.

You will be pleased to read that the deep-cell foundation took first prize for the best and most practical new invention for the bee-keeper. You know Toronto still holds the palm for having the best and largest exhibit of apianian products on the continent. The award will, I believe, prove to be a judicious one. R. F. HOLTERMANN.

Toronto, Sept. 3.

[As we have found instances where the deep-cell foundation has too thick a midrib, we propose to make it with natural bases. I don't suppose honey from the latter will look any better than that with flat bases, which took the prize.—Ed.]

#### DRAWN AND COMMON FOUNDATION FINISHED ABOUT THE SAME TIME.

We ship to you to-day a crate of honey. The 4 cases on top are the honey out of the supers you sent. You sent the supers too late for the willow-herb, so they are filled with goldenrod and wild daisy and boneset. The foundation in the full-drawn had nearly all fallen down, so it did not have a fair chance. If you had sent the foundation and let me set it, it would have had a better show. The bees went into the full-drawn first, but finished both about the same time. It was not a fair test. I should like to give it another trial next summer if you wish me to do so.

L. E. POWERS.

Thompsonville, Mich., Sept. 20.

ARTIFICIAL WAX SCALES TO ASSIST THE BEES  
IN COMB-BUILDING.

I have for some time wished to hear of your Mr. Weed, of foundation-fame, making a machine that would make wax scales—just such scales as the young bees make. I hope to live to see the day when the bees will be supplied with wax scales so that the colony can pick up the wax from a shallow box which will be placed in the bottom of the hive, and carry it to the surplus-boxes, and finish out the drawn-comb foundation, or use the wax scales to finish out the brood comb. A late writer questioned the propriety of purchasing foundation, as the bees made all the wax which would be necessary, and at a trifling expense in the way of honey. I was called to help a neighbor with his bees, and I took off for him the honey from two hives; the amount was 50 lbs.—30 from his best colony and 20 from the other—not one pound of which was in shape to sell. He did not use foundation. I suppose it was too expensive for him to use; but the loss of the sale on 50 lbs. of honey was also expensive.

I use foundation, and my best colonies so far have given 85 lbs., and are still bringing in honey, as the weather is very fine. I sold some honey at 12½ cts., and have had a fine home trade.

WM. H. EAGERTY.

Cuba, Kan.

[I have referred your letter to Mr. Weed, and he says the best and cheapest way to give wax to bees is to give it to them in the form of foundation. A year or so ago, when Mr. Weed was making experiments in bleaching wax, he left some long strips of foundation out on the grass in our apiary. During the time when honey was not coming in, the bees carried in a good portion of it, in little bits at a time. Bees gather wax in dull seasons, not particularly because they need it, but because they have nothing else to do.

Even if we could make small artificial scales, I rather question whether they would be utilized, especially so where the real article itself is being secreted in sufficient quantities in the natural way.—Ed.]

BEES DISAPPEARING IN CALIFORNIA; THE  
CAUSES.

To-day I read on pages 369 and 372, May 1, 1894, about a controversy you had with an Ontario bee-keeper—McFatric—about bee-paralysis. It struck me then that I should report to you about a new trouble that is threatening bee-keepers here. I found in the backyard in the mountains that bees would not breed up as strong as I wanted them to do; in fact, some colonies would dwindle down in spite of having ample brood to justify a strong colony. I laid the blame to a large flume which passes near the apiary, and in which the irrigation water runs down at a terrible rate. I saw, several times, bees swept along that went there for water; but since then I learned that nearly all bee-keepers in that locality complained about losing bees at a terrible rate without being able to account for it; i. e., not finding any dead bees in front of the

hives, as in bee-paralysis; also of losing queens more than in any previous year. I notice many bees coming home with ragged wings, as if they had to battle with strong winds. Upon closer investigation this state of affairs seems to exist only in a small district of Ettiwanda. Bee-keepers of Ontario do not complain, and have good to fair crops of honey, while at Ettiwanda the crop is from small to middling, although the locality seems to be A No. 1, showing hundreds of acres of white sage and other honey-plants.

I have made trips along the mountains away into San Diego Co., and visited many bee-keepers, and have not come across any similar case.

M. R. KUEHNE.

Ontario, Cal., Aug. 28.

DO BEES DISTINGUISH COLORS? AN INTER-  
ESTING INCIDENT.

I want to report a little experience which may be of interest to those of your readers who contemplate building house-apiaries. I have built one and painted it after Salisbury's advice. Starting at the south end it is 6 feet red, then 6 feet white, then 6 feet black, then 6 feet yellow, which brings us to the center of the building; then the rotation is repeated until the other end is reached. Bees were then put into the north half three colonies in each color. When they began to fly I noticed a few returning to the entrances in the south half, but particularly to the white part. As the bees in the north half began to increase in strength the bees returning to the vacant south half began to increase. This morning we had a light shower, which drove the bees home in great numbers, and the entrances to the white sections in the south half were covered with pollen-laden bees hovering round in a lost condition; while some returned to the other shades in the vacant half, the number was not so great as to the white. Does it not appear that, instead of bees not being able to distinguish colors, it is such a conspicuous and all-sufficient landmark that they neglect all other bearings—and particularly a clean white, which is very conspicuous, even at a great distance? As I look out of the window I can see hundreds of bees hovering around those vacant entrances. It looks as if I should have to paint them over again, so that no two shades be alike. I might say further that it is 24 ft. from one section of white to the other, and one is near the end of the building, and the other near the center.

A. E. TRUSSLER.

Trout Creek, Ont., Can., Sept. 6.

SMOKER FUEL; CORN-HUSKS, ETC.

In GLEANINGS for Aug. 15, page 603, I read about smoker fuel. I have had many troubles with fuel, and have tried every thing recommended, almost as persistently as many people do for a cold, and with more or less the same results. The best thing for fuel is corn-husks, used as follows: Start your smoker with wood. I use elm and maple that is about decayed. It holds fire best; then have your wood well fired, two or three pieces, in

size from  $\frac{1}{2}$  to 1 inch square, 2 inches long; then put in some husks; blow up a little to start the fire on them, then fill up the smoker, packing them down tight with your thumbs and fingers, or a stick if thumbs and fingers are not handy. Blow up a little, or you may smother out the fire, and you will have a smoke that will be pleasant to look at. It is mild, does not make a hot fire; no sparks or ashes if you keep the smoker filled up occasionally, and packed down tight, after the first fire is partly burned. If husks are a little damp they make a greater smoke. Give this fuel a good and fair trial, and I am certain you will like it.

#### HOW TO KEEP ROBBERS FROM THE CRACKS OF HIVES.

I think it was some of our sister bee-keepers who suggested the use of a little fresh paint along cracks in hives where robbers were around trying to break one of the commandments. A few drops of coal oil squirted along and into the cracks will make them stop their humming around there, and will not daub or mar the looks of the hive. I have usually used a bunch of wet grass at the entrance of a hive robbers were trying to clean out, but not always with success. Just sprinkle a little coal oil on the grass, and observe the results.

JOHN CRAYCRAFT.

Astor Park, Fla., Sept. 6.

#### THAT YELLOW IMPORTED ITALIAN QUEEN; YELLOW FEVER INTERFERING WITH THE SOUTHERN QUEEN-TRADE.

The imported queen mailed us Sept. 20th arrived the 25th in excellent condition. The queen and every bee were as lively as could be. The queen is safely introduced, and is laying. By the way, this is the yellowest imported queen we have ever bought, and we are truly proud of her.

On account of the yellow fever, all trains stopped running here the 16th, the very day we wrote you with instructions to mail the queen the 20th. We had given the queen up as lost, but luckily we had one mail train the 24th, and one the 25th, and the queen came through. All mail matter has to be fumigated here, and we don't know how the queen escaped. Every thing is at a standstill here now, and we shall have to give up the queen business for the rest of the season.

CLEVELAND BROTHERS.

Stamper, Miss., Oct. 1.

#### THE NEBRASKA STATE FAIR; HOW ALFALFA CARRIED OFF THE FIRST PREMIUM.

*Bro. Root.*—I am just home from the State fair, in which the fellows from the alfalfa district, in the extreme western portion of the State, lugged off the premium for the largest amount of honey stored by one colony—186 pounds of comb honey. This is no supposition, but verified under oath of Mr. C. M. Luelling, of Beaver City, Neb. Here comes a lot of bee-keepers from a district where, but a year or two ago, we thought honey could not be produced profitably. The Nebraska State

fair was a very successful one indeed, and Nebraska bee-keepers are making arrangements to put up a fine honey exhibit at the Trans-Mississippi next year, and we earnestly hope that other States will fall into line, and let us see what can be shown in honey, etc.

E. WHITCOMB.

Friend, Nebraska, Sept. 27.

#### HONEY-CAKE RECIPES TESTED.

I just discovered your request on page 647 for tried honey-cake recipes to put in your leaflets. The one I sent you, that you will find on page 375, May 15, has been used in my family for 100 years, I think. When they took up the bees in the fall my grandmother used to make up a year's supply of the cake, so my mother tells me. The cake is not at its best until it is three or four months old.

The recipe on page 407, June 1, is first rate. We have tried it. It is good for immediate use, but improves with age, like most cakes in which honey is used.

E. D. HOWELL.

New Hampton, N. Y., Sept. 27.

#### LOCALITY GOVERNING TASTE.

Replying to Dr. Miller's Straw and your corroboration in regard to locality ruling taste, it seems to me the assertion is altogether too broad, for surely locality does not govern taste any more than it does quality. I find in shipping honey some prefer white and some dark in the same locality; and among my home customers the difference is more noticeable. Some prefer basswood, some clover, some buckwheat, and some others fall flowers, and some even the darkest and rankest-flavored honey-dew (when I have it); some say, "I can't bear the white honey at all," and they will take the darkest grades in preference, even at the same price. This reminds me that one time I attended the bee-keepers' convention at Madison, Wis. When the question of propolizing the hive came up, a learned gentleman argued that it was governed by locality. My argument was that the difference was in the different bees, that in my own yard some hives were literally plastered with propolis, while others of the same make were almost entirely free from it. Then this man arose and said it was no such thing—that *locality* governed wholly. Of course, he was away up in "G" in bee culture, so his theory was accepted by the convention as conclusive. As to which was correct, many of you can judge from personal experience.

Hillsboro, Wis.

ELIAS FOX.

#### LOCATION FOR BEES WANTED.

Will some of the bee-keepers who live between Washington, D. C., and Charleston, S. C., give the best location for bees, and what they gather from, say from the coast back one hundred miles? This is a favored strip of country in climate, but I never see any reports about bees.

EAST COAST.

[Will some one or more in the locality please reply?—Ed.]

## SWARMING A SWARM OF BEES.

I do not know any other word to express better what I mean than the one I use. I had a colony of bees that persisted in swarming, and I did not want them to; so, about every eight or ten days I would cut out all the queen-cells, but still they sulked and hung out in front of the hive, and built queen-cells.

They had plenty of room and ventilation inside, but still they seemed bound to swarm.

After cutting out the queen-cells four times I was looking at a great bunch of bees hanging out in front of the hive. I thought I would swarm them. I got a small branch of a tree and fastened it firmly in the ground, opened the hive, caught the queen, and placed her in a mailing-cage with a few attendants, and fastened the cage to a twig of the branch. I closed the entrance of the hive, removed the frames, placing a piece of canvas near the branch.

I brushed the bees all off the frames, putting them in an upper story; I also cleaned the hive all out. The bees clustered around the cage containing the queen, just like a natural swarm. I placed the frames back into the hive and prepared it as it was before I began my experiment. I let the bees stay clustered for one hour, then I opened the entrance of the hive, shook the bees in front, let a little honey daub the queen so she could not fly, and she ran in with the rest of the bees. Now for the results of the experiment.

The bees went to work at once, and have worked ever since, and have not hung out one particle. I would say, however, I changed the location of the hive, otherwise it was just the same.

Now, the question arises in my mind, "Is the clustering out of the hive for an hour what satisfied the natural propensity to swarm, or was it the fact that I moved the bees to another location?"

I do not remember of either reading or hearing of any one doing this way before to stop swarming. I have tried it twice this season, with good results. GEO. L. VINAL.

Charlton City, Mass.

## FOR LARGE HIVES; DEEP ENTRANCES.

There was a good deal said last year by writers in GLEANINGS and the *A. B. J.* about large hives; and those eminent bee-masters, the Dadants, claimed that the large hives were just the thing for us bee-keepers to use. I had been using a ten-frame hive whose frame measured  $8\frac{7}{8} \times 14\frac{1}{4}$ , inside measure. My bees that I purchased of G. M. Doolittle gave me 84 lbs. of comb honey last year in the afore-said ten-frame hive. Thinking to try the large hive I made a hive whose frame measures  $10\frac{3}{8} \times 19\frac{1}{2}$ , and transferred a swarm of the Doolittle bees, with their 9 combs taken out of Gallup frames, into the large frames I have mentioned. The bees filled out the large frames and loaded them with honey, and gave me 84 lbs. of surplus honey besides. My bees are all of the Doolittle stock; and while I have colonies in the smaller hive that gave the same amount of surplus, they did not

have to build so much brood comb. I believe the Dadants are perfectly right in their claim that the more work you set for the queen to do, the more she will do.

It was a real pleasure to see the bees come out of the large hive when honey was plentiful in the fields. The flow of honey came late, and did not last very long this year; and I tell you those large colonies did hustle to get the honey crop secured, and they got it too. I am very well pleased with the work done by the honest little workers. I was afraid at one time that I should not get any surplus this year; but I am happily disappointed.

On page 661, Sept. 15, you say, in your remarks on Mr. Gill's letter, "We expect to make our hives next year so that the entrances will be an inch deep and the full width of the hive," etc. The entrances to my hives are  $\frac{7}{8} \times 1\frac{1}{8}$ , or full width of the hive. Now, what I want to call your attention to is that your customers, in using your hives, will often want to almost close the entrance; and the best way to do so is to saw out sticks that will just fill the aperture. Most of the lumber to be had throughout the country is  $\frac{3}{4}$  instead of  $\frac{7}{8}$ , and you should make the entrance  $\frac{1}{8}$ ,  $\frac{1}{16}$ , or  $\frac{1}{32}$ , so that, by a little planing,  $\frac{7}{8}$ ,  $\frac{3}{4}$ , or  $\frac{1}{2}$  inch lumber will fill the entrance. Such blocks or sticks are far better than loose ones. I use two sticks, leaving the opening in the center of three or four inches in cool weather, and no blocks in summer time.

Cuba, Kan.

WM. H. EAGERTY.

## THE IMPORTANCE OF SHADE FOR BEES.

In looking at pictures in the *A B C* book and GLEANINGS and other journals, my attention has often been drawn to the fact that so many apiaries seem to be exposed to the direct rays of the sun; and in arranging our little apiary, shade was a matter of secondary consideration with me; but as the care and work with them began to increase we found shade a great benefactor. Yesterday, as I took a little stroll through our apiary, one colony exposed to the sun, without any shade whatever, attracted my attention by so many bees swarming in front of it and settling on all sides of it; but as I approached a little closer I found the bees considerably out of humor about something; and, having no veil on, they gave me to understand that I was on forbidden ground, and made me quicken my steps out of there. When my wife (who is the real bee-keeper) came home from the fair I related the strange behavior of that one colony, and she at once put on a veil and proceeded to investigate the matter, and found honey leaking out in front of the hive. Upon further investigation we found that not only had the three cases containing eighteen sections (nearly filled and capped) melted down, but every one of the ten frames in the lower part of the hive, filled with brood and honey, melted down into one mass, and every bee was drowned in its own sweet.

P. A. PETERSON.

Boswell, Ind., Sept. 9, 1897.

*J. H. J., Pa.*—There is no way that you could remove the colony from the oak-tree of which you speak, if the bees are in the body of the tree, except by cutting it down. If they are in a limb of the tree, you can climb it and cut the limb off; but before it is severed entirely from the tree you had better fasten a rope to it and let it down gradually, otherwise you will smash the combs and greatly enrage the bees. After the limb is down, saw both ends around the bees, and carry home just that portion which contains the colony itself. You can then transfer them at your leisure.

*R. A. L., Va.*—We should be inclined to believe that the colony you refer to has something that it recognizes as a queen. It may be a virgin queen that is very small—little if any larger than a worker. This would account for all the phenomena you refer to. If the hive were ours we would put perforated zinc before the entrance, and shake every bee out in front of the hive, and compel them to crawl in again; then watch closely for something that can not go through the perforated zinc. Virgin queens will sometimes go through the perforated zinc, but such cases are very rare.

[Just before the above went to press we had a letter from R. A. L., stating that he found a virgin queen by the use of perforated zinc, as above explained, and now his troubles are ended. He had previously thought the colony queenless, and had tried to introduce laying queens, but without success.—ED.]

*W. C., N. Y.*—Yours not dated is at hand. We do not remember the article to which you refer, which you say you sent us some years ago, and which we did not publish. You may rest assured it was not because there might have been some things in it with which we did not agree. In almost every issue of our journal we publish some things that are not in accordance with our methods of working; but we are glad to give place to them, because not all people can be induced to work by the same methods, nor to see the same thing in the same light.

Referring to the article which you have just sent in, you tell us of the good results you have secured by your method of wintering, but you do not tell what it is. The article as it is would be of no use to us.

Again, you speak of the great loss of bees throughout the country. I think you must be misinformed. The progressive, practical bee-keepers of the day suffer very little loss comparatively. We have lost scarcely two per cent in the last fifteen years, and among the modern progressive bee-keepers we would venture to say that the loss does not exceed five per cent on an average. If you care to submit your method of wintering, and in our judgment it seems to have merit, we shall be

glad to publish it in our journal. If we could see it we might possibly then discover that it is the same that many of us have been using for a good many years.

Now, I hope you will not think we are trying to cast discredit upon your idea—far from that. It is possible that you have a valuable invention, and that it might be worth much to yourself as well as to your brother bee-keepers.

#### TREATING FOUL BROOD LATE IN THE FALL.

*B. T. C., Maine.*—We would not advise you to burn any of your hives. In the case of the chaff hives, knock out the bottom that holds the chaff, pull out the chaff, and burn it. After you have the whole lot thus “unchaffed” immerse each one in a vat of boiling water, and keep it there at least forty seconds—a minute would be better. It is possible you may not be able to find such a vat; but I think if you were to load your hives up and take them to some cheese-factory you could be accommodated.

Another way to disinfect (and it may be just as good, and it is a good deal cheaper) is to paint the inside of the hives with kerosene, set fire to it with the cover off, and let the inside of the hive blaze until it is charred just enough to show that fire has been inside the hive. To arrest the further progress of the burning, throw in about two tablespoonfuls of water, clap the cover on, and the steam which will immediately form will smother the fire. This plan was recommended by J. A. Green, and I believe by him was found to be entirely successful. The only objection to it is that it leaves the hives blackened inside; but this does no harm, and it shows unmistakably that the hive has been disinfected. When the hives have been burned out inside, of course it is not necessary to remove the chaff.

In the case of single-walled hives I would by all means recommend immersing them in a kettle of boiling water, covers and bottom-boards and every thing, including smoker, honey-knives, and other tools. The honey-knives especially should be boiled thoroughly.

Now as to the treatment of the bees: It is so late (Oct. 5) that it is a question whether it would be worth while to try to save them. I would not advise you to destroy them, but shake them on to frames of foundation; and after they have starved long enough to be weak, dump about three lots of them into each hive, and then begin feeding. It may be necessary for you to do some returning from the old stands; but if the old hives are removed entirely, the bees will be sure to find the entrances of hives that contain bees; and as they will be so thoroughly mixed up, there will be no fighting. If you have forty colonies that must be treated, then you will have a dozen or fifteen, each of which will contain what was left of three colonies. By proceeding on this plan I think you will save the bees.

The honey you can extract and boil, as you suggest; but the combs and frames should be burned. It is useless to try to melt out the wax or to try to disinfect the frames. It can be done, but it does not pay.

#### BUCKWHEAT HONEY; CLAMS, LOBSTERS, ETC.

IN some families in York State it was something of a surprise to me that they should prefer buckwheat honey to the best clover, mountain sage, or alfalfa honey ever produced. Some of them, if they wish to treat you to their very best honey, will give you buckwheat. I suppose it is one of those kinds of honeys that we have to learn to like, just as we have to learn to like olives, oysters, clams, and lobsters. I tried to learn to like clams on my recent eastern trip, and I tried to learn to like buckwheat honey, but I failed signally with both. We are all glad, however, that there is a very large class of people who think buckwheat is the very best honey in the world; and were it not for this particular liking, many of the York-Staters would not be keeping bees as they now are.

#### WHITE HONEY FROM CUBA.

MR. FRED L. CRAYCRAFT, formerly of Cuba, but now of Astor Park, Fla., of whom mention was made in our last issue by our Mr. A. I. Root, has sent us up a sample of campanilla honey. When he was here in Medina he stated that Cuba produced large quantities of white honey, and their best was campanilla. It is of good body, almost as light in color as California sage, and quite the equal of it in flavor. In fact, it would compare very favorably with any light honey in the world. I do not know how much our Cuban friend has of such honey for sale, or how much he is expecting to have, owing to the war that is now unfortunately devastating that island. But there ought to be a good demand for it in the London markets, and I bespeak for it a good sale when peace shall have been restored in that beautiful island now desolate by the cruel hand of war.

#### FOOD ADULTERATION.

THE Department of Agriculture, Washington, D. C., through Mr. A. J. Wedderburn, is now making special effort to investigate the extent and character of food adulteration, and is desirous of securing all the information on the subject possible. Among other questions asked were: "Would a national food and drug law assist in preventing adulteration?" Also, "What is your opinion as to the extent of damage done to legitimate business by the imitation of brands?" And again, "Have State laws assisted in preventing adulteration, and to what extent?" Prompt replies are called for. We have already written, giving our opinion of the evil done to the honey business by the use of glucose, and saying that a national law is exactly what we need. We hope our subscribers will take the pains to write to Mr. Wedderburn, at Washington, D. C., care of Department of Agriculture, Divi-

sion of Chemistry, and let him feel that we are suffering from the glucose business, and that we need relief. Please do not put this off, but give it your immediate attention.

#### SWEET CLOVER—THE WHITE AND THE YELLOW; DIFFERENCES BETWEEN THE TWO.

I BELIEVE it has been stated in our columns that white sweet clover and yellow sweet clover were exactly alike except in the matter of color of the blossoms. Mr. E. T. Abbott, of the *Busy Bee*, and myself were sitting in the same seat in an electric car that was making its way to Niagara Falls, when suddenly he pointed to the roadside. All along the way there seemed to be literally miles of yellow sweet clover skirting the track. Mile after mile there was nothing but the yellow, and then occasionally there would be patches of the ordinary white sweet clover, and then it would change to yellow. Mr. Abbott called my attention to the fact that the yellow was a smaller plant. While the white at a short distance was from four to six feet high, the yellow was scarcely ever over two feet. The remarkable thing seemed to be that there was no white mixed in with the yellow. It was either one thing or the other.

I saw yellow sweet clover in only a very few places in York State. I have never seen it in Ohio or anywhere else. Whether the bees will work as well upon one as upon the other, I can not say. We were spinning along at such a rapid rate on the street-car that I had no opportunity for investigation, even if bees had been on the blossoms.

#### APIARIES IN SHEDS; GOING TO PICNICS.

THE editor of the *Amer. Bee Journal*, as well as your humble servant, has been out attending bee-keepers' picnics. At all events, Mr. York, with his office force, attended what was styled the "Honey Harvest" at the out-apiary of Mr. L. Kreutzinger, Aug. 21, 1897. Mr. K. had sent out nearly 200 invitations to his friends, and a picture of the company (for it would seem as if his friends all came) appears on the first page of the *Amer. Bee Journal*. On another page of the same periodical is a half-tone view of the apiary. This is said to be the largest one in Cook Co., Ill. The hives, instead of being on the ground, are placed under sheds facing each other in such a way as to shut off the wind and yet let in a flood of sunshine. From the looks of the picture it would seem as if the hives are handled from the rear. That being the case, the apiarist is in the shade. If his back aches in handling those hives near the ground on the first shelf, all he has to do is to straighten up and commence manipulating the hives on the upper shelf—about breast-high, I should judge.

In my eastern trip among bee-keepers I saw only one apiary the hives of which were in sheds, and that was at Mr. House's, at Marcellus, N. Y. This Mr. House (I have forgotten his initials) is a brother of Geo. W. House who a few years ago was connected with the *Amer. Apiculturist*. These sheds were arranged at the base of two hills facing each

other, and all over the hills was a heavy growth of timber. The place seemed to be an ideal one for an apiary, and "as pretty as a picture." I snapped my Kodak, but it was so late in the day I failed to get the pretty picture I expected.

#### THE HONEY EXHIBIT AT THE MARYLAND AGRICULTURAL COLLEGE.

From a private letter from Mr. Charles H. Lake, who had charge of the honey exhibit at the recent Maryland Agricultural Fair, we make the following extract:

The college exhibit of bees and honey was the drawing card, and was attended by at least two-thirds of the visitors, 33,000 in number. I refer you further to a clipping from the Baltimore *Sun*. It was one of the most successful exhibits of my life, and many congratulations were showered upon me.

From the clipping in question we make the following extracts:

In a large tent erected to the northeast of the household-department building is the interesting exhibit of the Maryland Agricultural College, which is confined almost exclusively to bees and honey. There are to be seen eight hives of bees, occupied in storing honey in the comb. There is also a large pyramid of honey weighing 250 pounds, representing the product of one swarm for a year. Besides this there are two specimens of white-clover honey. One is pronounced by an expert on bees and honey to be superior in quality to any exhibited at the Columbian exposition in Chicago, and the other is a very unique and valuable specimen found in the roof of a hive on taking away the honey.

A small pyramid shows fancy designs in honey and bottles filled with extracted honey made from several varieties of flowers. There are seventeen varieties of these, and they retain characteristic flavors and color of the plants from which they are derived. This exhibit is in charge of the college apiarist, Mr. Chas. H. Lake, who has been engaged in bee culture for forty-seven years.

#### BEE-KEEPERS AT NIAGARA FALLS.

AFTER the Buffalo convention the bee-keepers went to Niagara Falls in little squads. The party that I happened to fall in with was Messrs. D. N. Ritchie, P. H. Elwood, E. A. Wander, E. T. Abbott, and two others whose names I have forgotten. It was arranged that we were to meet Messrs. York, Miller, and a number of other bee-keepers, on Goat Island; but somehow we "missed connections." Of course, I took along my Kodak, intending to secure a snap shot of a number of the leading lights in apiculture, with the beautiful Niagara Falls as a background. Having failed to meet the other "crowd" I gathered our company into groups at several different picturesque points, and "pressed the button." In another column I have reproduced a "shot" of the gentlemen just as I hit them standing upon a rock, with the Horseshoe Falls for a background. The fog, or mist, arising from the falls almost obscures the famous horseshoe. The wind was blowing quite hard, and it will be noted that every man in that crowd was obliged to cram his hat down level with his ears, or stand a good chance of losing that important piece of wearing apparel—just as I did, in fact, a few years ago, lose mine upon almost the same spot.

Well, to return. Our crowd took in the Falls generally, ate dinner on the Canada side, just to see how it would seem, you know;

went down the Gorge, passed the Whirlpool Rapids, and to Lewiston. All the way down I took snap shots of the rapids while the car was going at full speed. One lady curiously remarked, as she watched me taking pictures while the car was under full motion, "I don't see how you get a picture when every thing is going." "I catch them," said I, and I did. Another old lady wanted me to let her look into the camera to see how it looked, and whether the picture was good or not. That, of course, I could not do, as the film had to go through a process of chemical manipulations before it came out a picture.

I hope the view of the bee-keepers on the rock will appear better than the picture in our last issue showing some leading bee-keepers at the boarding-house. This picture did not "work up on the press" as I hoped and expected it would. I trust the one I have shown in this issue will come out better. Half-tones are very uncertain, and one can never tell in advance just exactly how they will behave until they get on the press.

W. A. SELSER.

AS Mr. W. A. Selser, of Philadelphia, has of late been creeping rapidly to the front as a leading bee-keeper, queen-breeder, honey-buyer, and supply-dealer, I thought our readers would like to see a picture of the man, more especially as he believes in *paying cash* for honey rather than taking it on commission. He did not have a photo of himself alone, but had one of himself, wife, and baby, and, "would that do?" I told him to send it on, of course; and when I saw it I was glad that he didn't have a picture of himself only. I sometimes think it is selfish to show a picture of one half and not the "other half," for many a man is what he is because of the good wife and God's greatest gifts to the home—children. The cut is shown elsewhere in this issue.

I solicited a few facts for a "write-up" to go with the picture, and here they are:

W. A. Selser was born in 1859, in Philadelphia, in that section of the city then called Northern Liberties; was educated at the public schools, afterward attending the Philadelphia College with the idea of studying for a profession. A year before graduation he was taken sick for six months; then having a good offer of learning the morocco-leather business, he entered the factory of Wm. R. Stewart & Co. In about two years Mr. Stewart failed, and Mr. Selser entered the establishment of Selser & Bro., his uncles, importers of foreign fruits, a business established by his father, who died when the subject of this sketch was but twelve years old. He traveled much for this firm, remaining with them six years, when a chance occurred to take an interest in an old-established morocco-leather firm, starting as Selser, Meurer & Co., and finally merged into the Quaker City Morocco Co., of which he was treasurer, employing 400 hands, and doing a business of three-quarters of a million dollars a year. In 1892, through the heavy defalcation of their trusted buyer of hides, they were compelled to

give up business. Mr. Selser then took a trip to Florida for the old house of his uncles, visiting many of the bee-keepers there. On his return he stopped at Medina, staying over night with The A. I. Root Co. It was a case of "mutual admiration" as he says, and he on his part was so impressed with the supply business that he made arrangements then and there to handle the Root goods in his city.

He became interested in insects while attending school, and afterward gave special attention to the study of zoology, and bees in particular. In 1889 he started an apiary of 15 hives in his garden, for pastime. In 1892 he bought out a large apiary in Chester, and now has one house-apiary and three out-apiaries that he manages himself, aggregating 400 colonies and nuclei, and has control of 17 apiaries in other States. He makes a specialty of extracted honey, and expects to bottle this year over 15 tons.

In 1894, when the pure-food law passed the Pennsylvania Legislature, Mr. S. took a special course in chemistry under Prof. Wallace, to detect the adulteration of honey sold in his market.

Mr. Selser married in 1889; moved to Jenkintown, a suburb of Philadelphia. The cut shows his wife and little girl, Margaretta, four years old. The latter helps him in his business. She dons the veil, holds the frames for her father while he works in the apiary, and is no more afraid of bees than a veteran. Mr. Selser has a sister three years his junior, who has been a great help to him in his business.

The best thing I can say about our friend is that he is an earnest Christian, and so far our business relations with him show that he does as he would be done by.

#### NOTICE.

To all new subscribers, and also to those who renew before their subscriptions expire, and inclose \$1.00, we will send the *Busy Bee*, a monthly bee-paper, in addition, free.

#### SECTIONS WITHOUT BEE-SPACES AND CLEATED SEPARATORS; ONE-PIECE AND FOUR-PIECE SECTIONS FOR SCRAPING.

At several of the different yards I visited in York State I noticed that the four-piece sections were still being used in preference to the one-piece, notwithstanding the former cost more and take more time to put together. I never could understand exactly the reason unless it was that there was a time when the one-piece sections that used to be sent out would, when folded, incline toward a diamond form rather than a true square; and this "naughty corner" induced many to use the four-piece section. In the last few years nearly all the manufacturers, I believe, have discovered that it is perfectly easy to make the one-piece assume a true square as well as a diamond form; and latterly I have been noticing that the one-piece was creeping into the territory of the four-piece. But, as I said, several are even now using the four-piece, and this preference seems to be due to the fact that these sections offer facilities for scraping that the one-piece

with the ordinary score cut out for openings does not. It will be remembered that the four-piece section has an opening clear across the top and bottom of the sections, while the one-piece has an opening that is scored out and reaches to within  $\frac{1}{2}$  inch of the corner. At one or two places I was shown that the scraping-knife could at one sweep go clear across the top edge of the section, and at one sweep go down the side edges of the section. But in the case of the one-piece the knife had to dip down and out again.

#### MORTON'S NO-BEE-WAY SECTIONS AND MORTON'S HONEY.

At the apiary of Mr. Miles Morton, Groton, N. Y., to whom I have already referred, I found not only four-piece sections, but sections with practically no openings at all, the bee-space to the sections being effected by cleats on the separators. I said "practically no openings," for the top-bars of the sections were narrower by  $\frac{1}{8}$  inch than the side-bar. In other words, there is an opening  $\frac{1}{8}$  inch wide between the tops and bottoms of the sections when put close together. Of course, this would not be room enough to let the bees between the sections. Accordingly, separators are used cleated, the cleats being  $\frac{1}{8}$  inch thick, and so spaced on the separator that

they come just opposite the upright edges of the sections. The  $\frac{1}{8}$ -inch-thick cleat, and the  $\frac{1}{16}$  inch in the sections, make just exactly a bee-space of  $\frac{3}{16}$  inch. As these separators are cleated on both sides, the cleats being held in position by glue, the regulation bee-spaces are preserved in the sections while in the supers. But you may ask why Mr. Morton did not have all the bee-space in the sections like those all the rest of us use, instead of  $\frac{3}{16}$  of it in the separator. I can answer this question by saying that, if you were to look over his lot of comb honey, you would at once see the reason. The comb surfaces come within  $\frac{1}{8}$  inch of a straight edge resting across the sides of the section, and  $\frac{1}{16}$  inch from the same straight edge reaching across the tops and bottoms of the section. The consequence is, the section appears to be fuller, and looks, oh so much nicer! When I looked over this lot of honey I said, "Why, you have selected this because it is filled out well."

"No, sir," said Mr. Niver, Morton's "brother-in-law." "It has not been graded at all."

Then I looked over some supers just as they came out of the hive, and pulled out sections here and there at random. They were all alike. Mr. Morton's honey would grade, according to my notion, extra fancy right alongside of ordinary honey placed in sections having a bee-space, that would grade only about No. 1.

#### CLEATED SEPARATORS EASILY AND INEXPENSIVELY MADE; GLUE INSTEAD OF NAILS.

Perhaps it may occur to some that a cleat-

ed separator, such as I have just described, would involve the use of a great many pieces, and a good deal of work to put them together. For the ordinary  $4\frac{1}{4}$  section there would be, in fact, 11 pieces. I must acknowledge that I myself felt that the nailing-up of such a separator would be simply awful—that one would get tired of putting with so many little pieces and so many nails to get one separator. For several years back we have been making cleated separators; and till lately I felt sorry for any one who thought it necessary to use such a clap-trap. After being at Miles Morton's I not only saw the great value of such a separator, but found that the labor of putting it together could be very greatly reduced by using cabinet-makers' glue. Mr. Morton uses a form which spaces the long strips and the short ones just so far apart. The separate pieces are dropped into the form, and those surfaces that are to come in contact are smeared with cabinet-makers' glue, when the strips are laid in their proper positions. As the form is made to take a deep pile, the stuff is piled up, as it were, like cordwood, and very rapidly, too, by any kind of cheap help. After the pile has been made, the tier of separators is lifted out of the form very carefully, set to one side, and a weight placed on top. Of course, in a few hours these separators are ready for use. You may think that the glue would not hold; but Mr. Morton assured me that he never had any of his separators break at the glued joints. In my hands is part of a separator that has been glued together. I have tried to pull the stuff apart with my fingers, and actually have had to give it up. (A later attempt separated the parts, but the wood itself gave way and not the glue.) There is every thing in having good glue. The ordinary prepared article will not be suitable for such a purpose; and, besides, it would be too expensive.

#### THE PRETTY EFFECT OF THE NO-BEE-WAY SECTIONS FILLED WITH HONEY.

You can get somewhat the effect of the no-bee-way sections filled with honey, but not entirely, if you take a series of your sections that are filled out about equally, and, with a common smoothing-plane, plane the edges of the wood of the section until the bee-space, or scoring-out, almost disappears. Now stand four of such right by the side of those that have not been planed off; then note how much prettier the former look. J. E. Crane, of Vermont, showed me this trick seven years ago.

I was not surprised when Mr. Morton's brother-in-law, Mr. S. A. Niver, told me he could get a higher price every time for Mr. Morton's honey because it looked so plump and nice—much more so than he could ever get for sections having a full bee-space.

Coming home, I found our friend Mr. Francis Danzenbaker, who uses a section, it will be remembered, that has a bee-space on one side, and none on the other. On the table he placed four sections filled with comb honey, with the bee-space side *toward* us; and from the same lot he placed four other sections, exactly like them, also filled with comb honey,

with the no-bee-space side facing us. Any one who could not see that the last four looked several cents better per pound than the first four mentioned must be blind indeed. I said to Mr. Danzenbaker, that "the side of the section having no bee-space on it looked so much nicer, why not go one step further and take the bee-space off the other side as well, and use a double cleated separator?" He was afraid that no-bee-space sections would not crate well in the shipping-case; and he thought, moreover, that such a section looked too lean when looked at from the side.

So far as the crating part of it is concerned, Mr. Morton crates his honey right along without any difficulty, but he always uses a piece of thin veneering between each row of sections. So far as the leanness was concerned, I must say that I could not see that it made any practical difference.

#### THE ADVANTAGE OF A NO-BEE-WAY SECTION FOR SCRAPING.

Ever since I have been home from the East I have been thinking of the great advantages that would accrue from sections having no bee-space—sections perfectly flat on both sides. They would be cheaper and easier to make, far handsomer when filled with comb honey; and when it comes time to scrape their edges, how much easier to go over them with a scraping-knife! Just picture, for instance, in your mind's eye, a section having a perfectly flat side so far as the wood is concerned, without any bee-space. Now, in your mind's eye also take a common case-knife and clean the propolis off from that whole side of the section, with *one sweep*; no jutting corners nor curved openings to dodge into and out again—absolutely no danger of gouging into the honey. If you can't see that in your mind's eye, take a smoothing-plane, cut off enough wood from a section to obliterate the openings or bee-ways on both sides, top and bottom; then take a case-knife and lay it near one corner and notice how easily you can scrape the whole four sides at one swing of the knife.

#### THE SAVING IN SHIPPING-CASES.

This is not all. With the no-bee-space section we effect a great saving in shipping-cases. Suppose, for instance, you take a  $4\frac{1}{4}$  section, and leave off the bee-ways, and you will find it to be  $1\frac{1}{2}$  inches full instead of  $1\frac{3}{4}$ . If we use double cleated separators, it will hold just as much honey as the  $1\frac{3}{4}$  with openings. Well, then we can put in a shipping-case that ordinarily holds 24 one-pound  $1\frac{3}{4}$  sections, 32 sections of the same kind without the bee-spaces or bee-ways. The gain to the honey-producer in shipping-cases is just exactly *one-third*. Or, to put it another way, the honey-producer would save one-fourth the cost of the shipping-cases by the adoption of sections with no bee-ways. Besides this great saving, he will have honey that will run at least one grade higher in the market.

#### HOW THICK TO MAKE THE CLEATS TO CLEAT-ED SEPARATORS.

But, you may ask why Mr. Miles Morton

does not use sections without any bee-space whatever. I do not exactly know, unless he thought that leaving the  $\frac{1}{8}$  inch space in the section on one side would allow the sections to crate together better. However that may be, I think the difficulty is entirely obviated by using the thin veneer stuff between the sections. As I will presently show, by a certain adjustment in the *thickness* of cleats on the separators, we can make the faces of the combs as near the edges of the sections as we like. If we make the cleats full  $\frac{1}{4}$  inch, then the faces of the combs would be just even with the edge of the sides and tops of the sections; but if we make them  $\frac{3}{16}$  inch, or scant that much, then the surface of the comb will retreat from the straight edge across the sides of the sections  $\frac{1}{16}$  inch. If we make the cleats only  $\frac{1}{8}$  inch thick, then the surface of the comb will retreat back  $\frac{1}{8}$  inch from a straight line across the edges of the section. This last thickness,  $\frac{1}{8}$  inch, would be the proper thickness of a cleat on the cleated separators; and to secure the necessary bee-space or opening at the bottom, the separator itself should be just enough narrower than the inside height of the section to make the opening  $\frac{3}{16}$  wide.

#### NEW-STYLE SECTION ADAPTED TO OLD SURPLUS-ARRANGEMENTS.

Now, about this time I imagine some of you saying, "Look here, E. R. R., are you proposing to foist upon the bee-keeping world an entirely new section, thus compelling us to discard our supply of surplus fixtures in the way of T supers and section-holders?" Not at all. If you will take one of your  $1\frac{1}{2}$ -inch sections and plane off the bee-way as I have described, you will see that you can use them in your hive-crates just as you did your old ones. The T super itself would be very nicely adapted to such a section; so also would the section-holder arrangement. The cleated separator would take up the spaces formerly occupied by the bee-ways themselves, so your crates and fixtures will come out just the same as before.

Now, perhaps another question may arise: "Do you propose to discard  $1\frac{1}{2}$  sections in your manufacture and substitute in their place the no-bee-way section?" Not at all. That is to say, we will keep right on making the old-style sections as above, because, no matter how good a thing may be—no matter how much saving it may effect—it would take time, under the most favorable circumstances, to make the change. But all of our readers who appreciate the merits of this section, and want to use them another season, can be accommodated. Space will be given in our forthcoming catalog to describe the sections and other changes. Then our customers can have an option. But, of course, the old-style section will be made regular, and all will be supplied as otherwise ordered.

No doubt some of you will suggest at once that the cleated separator will cost more. Yes, a little more; but in the hive combination it would cost no more, for the reason that, were we make a little increase in one way we make a saving in another. The new-style separator

we hope to make of lumber that we ordinarily burn up, instead of cutting up good timber as we now do for the ordinary slotted separator.

#### THE CLEATED SEPARATOR AN OLD IDEA.

I have no engraving yet that shows the cleated separator I have been talking about, but have something pretty nearly like it. And this leads me to the idea that the cleated separator is not a new idea by any means. If you will turn to GLEANINGS for Nov. 1, 1888, you will find what I have been describing is illustrated and described by Mr. Oliver Foster; and at the beginning of this article I give the illustration as it then appeared; and right here will I give some of the good features enumerated by Mr. Foster.

1. It furnishes free communication from side to side.
2. It will not bend nor wrinkle as tin does, nor warp and split as ordinary wooden ones do.
3. It serves as a support for the sections (where the bee-space is used), doing away with the necessity for T rests or other supports under or between the sections (except at ends of case).
4. The lines of propolis resulting from the contact of these supports are thus avoided.
5. No trouble with sections catching on the edge of tins, nor with getting in the last sections.
6. The outside rows of sections can be easily turned to the central part of the case for completion.
7. The cost, I think, will be less than that of any perforated separator yet offered.

You will notice, incidentally, that the separator is made up of three pieces. Miles Morton's are made much in the same way, only his cleats are glued on.

The bees can go back and forth through such separators. This one feature alone is worth all the separator costs, because it permits of the combs being filled out fuller, owing to the fact that each individual section is not shut up completely by itself.

At a later time, in GLEANINGS for March 15, 1895, Mr. B. Taylor illustrated and described a similar separator. Mr. Taylor, in speaking of the advantage of such separator, says:

TAYLOR'S SEPARATOR.

This gives perfect sections that weigh a scant pound each when filled. The honey on both sides of the section comes within  $\frac{1}{8}$  inch of the edge of the section, and is never broken in removing the separator, and the surfaces are  $\frac{1}{2}$  inch apart in crating. In crating sections filled between common flat separators, the surfaces of the combs are  $\frac{1}{2}$  inch apart, and require a larger crate for the same number of pounds.

Mr. Miles Morton has been using his arrangement for some eight or nine years, and Mr. Danzenbaker has been using something similar for about two years.

Now, then, brethren, the subject is open for discussion. I suppose there will be some criticism and some objections to such a section. Let us have them all now. I wish especially we might hear from those who have been using an arrangement similar to this, as to how they like it. I have not attempted to give all the points for the section.

#### A VISIT TO LANDRETHS' GREAT SEED-FARM.

I made another blunder here in not having an adequate idea of my undertaking. When we reached the station, and were informed it was only a mile to Landreth's farm, and a good nice walk, friend Selser and I decided to go on foot because we had been sitting all the morning. Well, we did get on to the Landreth premises after walking about a mile; but it was fully another mile on their own premises before we got into the heart of the business. What I should have done was to procure first a livery, especially since my arrangements permitted me to spend only two or three hours at the place. When you undertake to visit a garden that covers something like two square miles, you have a pretty big amount of travel on your hands, even if you take only a hasty look at the different fields of different crops. A great many times we are disappointed when we get really into grounds that we have read about in seed catalogs; but in this case it was just the other way. I had no conception of the immense size of the Landreth plantation, the number of buildings, the number of hands employed, the different kinds of machinery, etc. Some of the buildings are quite old, it is true; but many of them are very pretty, and the grounds, as a rule, are nicely kept in beautiful order. A great stone warehouse, so old that it is covered with English and Japanese ivy, especially attracted my attention. It is 200 feet long, 40 feet wide, and 3 stories high, and was built a good many years ago.

A little later, when I was asking them how they managed to cure their onion-sets so they kept from freezing, and also kept dry, I was told they were all placed in this great stone warehouse after the weather becomes too severe to leave them in the lofts which I will describe presently. When I inquired if they ever used fire heat to dry them out, the reply was, "Oh! no, no! Onions and onion-sets must be kept just as dry as possible. They must be dry, and at the same time cold; and the old stone warehouse that keeps out frost without the aid of any artificial heat is just the place to keep onion-sets from either freezing or sprouting."

Long before we got to the center of business I told friend Selser that there was an odor of something that, although familiar, I could not quite recall to mind what it was. After sniffing the air several times, however, I ejaculated, "Oh! radish seed—that is what I have been smelling; and when we get a little further you will find they have been thrashing out radish pods to get the seeds." When we got along far enough, that is exactly what we found they were doing.

I was greatly interested in their arrangements for curing onion-sets; and in a little time we saw, away off in the distance, almost

as far as the eye could reach, field after field covered with queer little structures that looked like chicken-coops—the letter A sort. I said to myself, "Why, the Landreth's can not be in the poultry business to such an extent as this, surely." Then I found that these were trays on which the sets were cured after being sifted from the dry earth. Each tray holds two bushels of sets; and two trays are set together, letter A fashion, only not quite so tall. The trays are put in a long string, touching each other where they rest on the ground, and touching each other also where they fit together above ground, something like this:

This permits the air to pass all around under the trays as well as over the surface. It also admits the sun on all sides. I do not know what they do when it rains, but I suspect they manage to get them under cover, at least to a great extent, before any rain comes on them. When they are sufficiently dry they are put into large sacks and piled up high on wagons made on purpose, with sloping sides. I should have said that, in their business of growing onion-sets, they use something like 20,000 trays. Although I did not measure the trays I should think they are perhaps  $2\frac{1}{2} \times 3$  feet. The bottom is thin light lumber, with some cracks to let the air through, the said cracks being too small to let even small onion-sets get out. Their crop this season will amount to about 80,000 bushels. Now, do not get the idea that I mean *eight* thousand. It is really *eighty* thousand bushels. They sometimes sow for onion-sets as much as 8000 lbs. of onion seed, and 250 men are frequently employed in caring for the crop. After the onion-sets are hauled in on these great wagons, they are put through a machine run by a steam-engine that sorts out the different sizes. I believe the orthodox size for onion-sets is not over  $\frac{3}{4}$  inch in diameter; but they can be as small as you choose—the smaller the better. Those that are over  $\frac{3}{4}$  inch in diameter are sold at a less price, and many are used for pickles. Those still larger are sold for table use for whatever they will bring in the market.

After being passed through the machine the sets are elevated by horse power up to different lofts in barulike buildings made on purpose to store them. The floors in these lofts are made so close together that one has to stoop over in walking about. There are plenty of windows so the hot air of an August day may circulate through and under all the floors. The sets are stored on the different floors, say from four to six inches deep; and I never saw a prettier sight than some of the Bloomsdale pearl onion-sets—miniature onions, perfectly ripened, and they were indeed veritable "pearls." I am not sure but they were handsomer to my eye than would be the real pearls glistening in the crowns of royalty.

Like ourselves, the Landreth's have discovered that it is cheaper to have their own repair-shops than it is to depend upon anybody else for repairing their implements. In fact, all the wagons, carts, and other vehicles

used on the premises are made by their own mechanics; and many machines that would never be needed anywhere else in the world are made here for their special business. I omitted to tell you that the machine for sorting onion-sets is a combination of cylinders made of wire screen. One cylinder goes inside of the other, and they are of different lengths. The arrangement is such that, when the sets are poured in from an elevated platform, each kind runs out down to the ground into its respective sack, ready to be pulled up into the buildings before mentioned.

The Landreths, after long experience, select the ground best adapted to growing each vegetable. Not only do they select their fields on the Bloomsdale farm, but they have a branch seed-farm at Norfolk, Va., of more than 1000 acres, for growing seeds than can be raised to better advantage further south.

Of course, there are lots of boys and girls on the Bloomsdale farm; and provision is made for these at a very pretty schoolhouse. There are many men who have spent all their lives with their families in the employ of the Landreths. No wonder; for this institution has now been running for 111 years. I can not imagine a prettier sight than a field of onion-sets with men, women, and children engaged in cultivating the crop and keeping it clean. Very likely they have a church as well as a schoolhouse; but I forgot to inquire in regard to that; and possibly a Sunday-school and Endeavor Society. Perhaps some of the Landreths will tell us about it.

As the older members of the firm were absent, one of the grandchildren (or possibly great-grandchildren) showed us around. If I am correct, it was Mr. Fletcher Landreth, a young man of eighteen.

The testing-grounds, where all varieties of garden vegetables advertised by the Landreths or anybody else are tested every year, are so extensive as to bewilder one. Why, it would have taken ever so much more time than I had allotted to my visit, to look over the testing-grounds alone.

Of course, the Landreths have a side-track of their own for loading up cars. These side tracks run mauve in from the great cities, and carry out crops of seeds. Ever so many carloads of onion-sets alone are shipped north, south, and west every year. In their testing-grounds sometimes 5000 different varieties are tested. One who has undertaken on a small scale to determine which is the best vegetable out of half a dozen sorts can form an idea of the perplexities of this testing business when it runs up into the thousands.

When you stand over on the railroad track and take a birdseye view of the farms, a very pretty effect is noticed by the inscriptions on the roofs of the buildings. For instance, one great barn will have the word "Landreth's" covering the whole roof. Another building, some distance away, has the word "Garden." Still another barn has the word "Seed," in gigantic letters; and the last one of the group of four will have the word "Farms." All together it reads, "Landreth's Garden Seed Farms."

I was surprised to learn that their cabbage from which they grow their seed stands out in the open ground all winter. I was told about their special treatment necessary to do that, but can not now exactly recall it to mind. In fact, I asked so many questions it is not a little strange that I can not remember the answers to them all. I do not know how many buildings there are on this huge farm, but enough, I assure you, to make a pretty good-sized town. They are mostly in groups. Sometimes the groups are a quarter or even half a mile apart. This is to facilitate getting the crops under cover quickly when rains come up suddenly. Of course, they have steam thrashing-machines and special separators for working every variety of seed required in the home garden. It would not be at all strange if, with their great facilities for doing the work on a large scale, they could furnish good seed for less prices than it would be possible to do on a small scale. I believe most of the seed-farms in the vicinity of Philadelphia purchase their onion-sets of this firm.

By the time we got around to the depot we were pretty well tired out, I assure you, as it was a hot August day, and I regretted again that I did not know better than to undertake to go on foot all over the Landreth establishment in just two or three hours.

By the way, the proprietors have a beautiful album of photographic views of the premises I have tried to describe. There are 24 pictures in all, and there are some of the finest half-tone views in it I ever saw in my life. And, by the way, the Landreths were one of the first to adopt the custom of using photographs from life rather than exaggerated paintings of the products and premises. I was pleased to see on the front cover of said album this little motto:

NO ORDER IS TOO SMALL  
IS TOO MUCH TROUBLE.

I don't know but this would be a pretty good text for some of us who do business on a comparatively small scale.

HOW TO MAKE YOUR TOWN ORNAMENTAL AS WELL AS USEFUL.

A little place called Blake, just seven miles from Medina, comprising a store, blacksmith shop, and about a dozen houses, has just met a streak of luck. The storekeeper, right on the corner, bought about half an acre of land, and proceeded to erect a dwelling. The first thing was to procure a good well of water. He paid some men \$24.00 for drilling 48 feet; and at that depth they struck a vein of water that fills a three-inch pipe, and throws it two feet above the surface of the ground. It will not go any higher than two feet, even if the three-inch pipe is reduced to half an inch; but, of course, the larger the pipe the larger the volume. Although this well was drilled only about four weeks ago, the owner has already piped it over into the road, or cross-roads, rather, right in the center of the town. Here he has a very pretty round pine tank, perhaps ten feet across and four feet high. As the well on his premises is a few feet above this tank, a very nice little fountain sends a stream up

several feet in the center; and some beautiful goldfish delight the urchins and other people as they sport in the sparkling spring water. Half a dozen teams can drive up to the tank and drink all at once; and in consequence of the severe drouth now prevailing, farmers are coming for miles around with sleds, stone-boats, etc., loaded with barrels, drawing water home to their stock; and these sleds and stone-boats did the writer quite a service, for they converted the loose dust into a bicycle-track almost equal to asphalt pavements. The head of water is sufficient to pipe it right into the greater part of the dwellings of the little town, and, in many places, clear into the upper rooms. The well belongs to Mr. A. K. Freedt, who owns the store and runs the postoffice on the corner.

Now, then, ye people who live in little towns like the above, you probably can not all have an artesian well; but you do not know this really until you have drilled down a hundred feet, more or less, to find out. But every little town can have a windmill and a beautiful watering-place right in the center of the town. The watering-place I have just described did not cost more than ten or fifteen dollars, goldfish and all.

---

## OUR HOMES.

---

Come unto me, all ye that labor and are heavy laden, and I will give you rest.—MATT. 11:28.

Permit me to say that most of my talk on this text is borrowed from a sermon delivered by Rev. A. T. Reed, at Canaan Center, Wayne Co., O., on Sunday evening, Oct. 3. I shall take only one point of his discourse. Jesus calls all men unto him. "Come unto me," he says. He does not say, "Come to truth, come to honesty, come to temperance," nor even to purity of thought. He sums it all up by saying, "Come unto me, all ye that labor and are heavy laden." Now, since the world began, people have tried to substitute something in place of Christ Jesus the Son of God, the mediator between God and man. They have said, and do say now, "My religion consists in being honest; in being upright in deal, and in doing as I would be done by." These people reject the idea of Christ and the Christian religion. They say, if a man would do as he would be done by, is honest and fair toward all his fellow-men, pure in heart, and temperate in his habits, that is enough; and they declare that they are willing to take their chances with the best professing Christian among us. Very likely there are people who set a better example in many of these things than do a good many professing Christians. I confess it has always seemed very hard for me to admit that honesty, purity, and temperance, count for nothing—or, if you choose, count for comparatively nothing when the person refuses to accept Christ Jesus as the Son of God. Perhaps you have heard ministers talk on this subject; and very likely you have not been satisfied with their arguments and statements. Let me give you an

illustration, from Bro. Reed, that has made it plainer to me than it ever was before.

Suppose a man in your neighborhood wants to get some public office. He knows what people demand or desire in a public officer. He sets to work with energy and zeal to be a better man. He begins to be kind and neighborly; pays up old debts that nobody ever expected to get; apologizes for his past shortcomings, stops using tobacco, possibly beer-drinking also, becomes an advocate of temperance, has respect for the Bible and Christianity, and makes a sudden and apparently complete change in his whole life. Does this make him a Christian? He may, for the time being, present so clean a record as to put the average Christian to shame. But it is all a *policy* matter. His *heart* is not changed at all. He simply wants to get elected to office; after that he may hold out in his new "departure" or he may not. Perhaps I may say, parenthetically, that the chances are that he will not. What do you think of such a man? Is he a better man than he was before? Well, it seems a little hard to say he is not any better. The effect of his whole life on his neighbors and on the community is certainly better; and we all rejoice to see even such reforms. But how about the man's heart? He is trying to make all his friends and neighbors think he is a better man than he really is. To call things by their right names, he is now, with all his goodness, purity, and temperance, only one sort of hypocrite. Before, he acted out just as he felt. He seldom "put on" any thing, or even tried to make believe he was something he was not. I am sure you see the difference. The man who cultivates all of these virtues from the *right motives* desires to be better in *God's* sight; as to what the community or neighbors may think of it, is a secondary matter.

Now, the Bible teachings are to the effect that accepting Christ as the Son of God sums up *all* these virtues I have enumerated, and even many more; in fact, it sums up all that is good in the human heart. Accepting Christ as your Savior, and your only hope of pardon, embraces all of these things. He is the very essence and embodiment of truth. When Pilate asked him, "Art thou a king?" Jesus answered, "To this end was I born, and for this cause came I into the world, that I should bear witness unto the truth." Permit me to say that I have never yet found a moral man who lived up to all these things as he claimed to do. For a time it would seem as if he were an honest doubter; but where I become intimately acquainted with such people I have always, sooner or later, discovered something that seemed to be a reasonable explanation why they should so persistently refuse to accept Jesus Christ as the Son of God.

Now, friends, permit me to use an illustration that Bro. Reed did not use; and it is a subject that has been lying on my mind, and has been making me feel troubled and anxious. Jesus, when he said, "Come unto me," did not say, "Come and be a Congregationalist, a Methodist, a Baptist, an Episcopalian," nor any of these different sects or denominations.

He said, "Come unto *me*." After having come unto him, and making him first and foremost, there certainly can be no objection to uniting with any denomination you think proper. But denomination must never be first. In communion seasons I have frequently heard pastors, in inviting people to partake, say, "Let all who love the Lord Jesus Christ partake with us." I do not know whether this is always the case or not. It seems to me as though it should be so.

When I was having that pleasant trip with Mr. Hugh Vankirk, of Washington, Pa., we passed quite a pretty public building near his home. He is five or six miles from the city, and the little station near his home is called Vankirk Station. There is no church within several miles. Friend Vankirk pointed out the building I mentioned, and I asked him if it was a church.

"No, Mr. Root, it is not a church—it is a Sunday-school. The building was made on purpose for a Sunday-school, and has always been used as such. Of late we have been having preaching almost every Sunday. The ministers are of various and different denominations; but as the audience is made up also of various denominations we have it understood that the speaker is not to use the house and occasion to further the interests of his particular school or organization."

My attention was aroused at once, and I asked a good many questions. The building was erected by the people. Friend Vankirk, who is a mason and brick-layer, laid the foundation and built the chimney. Others did likewise according to their trades. Then a large enthusiastic Sunday-school, with a fine library, was organized. The minister who preaches is paid cash down after the sermon; and, if I am correct, they have some money ahead. The Sunday-school teaches Christ Jesus and nothing else. The various ministers who come by invitation to preach, preach only Christ Jesus, and the people all come. If any particular denomination were to preach, there are a good many who would not come. We who live in country places know all about this. In little towns all over the United States there are often three or four churches—a good many times three—where there are not people enough in the whole three churches to make one fair-sized audience, or to pay a minister a decent salary. I have often thought, and frequently said, that it was a pity we could not do with these churches as the bee-keeper does with his weak colonies of bees when winter comes. He breaks up three or four colonies and unites them in one. If left to go through the winter alone they would all die, or pretty nearly so. United they make a rousing colony that can drive out intruders, and make a stand against any enemy. Is it not so, dear friends, with the churches? A saloon tries to come into a town. The people are so busy in settling differences between their denominations that they forget to fight the saloon-keeper, and he gets their boys away from the Sunday-school. If the little town were united—if the Christian people were all one body, pulling the same way, repelling sin

from every point of the compass—the saloon, the dancing-teacher, and the professional gambler would be afraid of them, and would conclude the town was not a good locality for their occupation. I do not know what should be done to bring about this happy millennium, where all people shall understand and say that the only really *important* thing in this world is to come to Christ—"come unto *me*."

Mr. Vankirk told me the people were all pleased with this union Sunday-school and union preaching. He said the only objection he had ever heard was from ministers themselves. Dear friends, perhaps I am getting on dangerous ground. If so, may the dear Savior set me right; but it is true that it is the *ministers* themselves who are greatly responsible for so many sects? Our own Congregational Church has made several blunders, to my knowledge, in building new churches and trying to build up a church where another denomination was not needed. Within ten miles of where I now sit a beautiful brick church with stained-glass windows stands unoccupied, or at least has preaching only at intervals by a pastor who does not live in the town. The expense of building this church pretty nearly ruined one or two good old farmers financially; and yet the church stands empty and unused a great portion of the time.

One more thing I want to speak of, and perhaps I am treading on dangerous ground again. The ministers of these three or four churches where only one is needed are very poorly paid. As they are poorly paid they have to work at something else to make a living. A cheap minister or a cheap school-teacher is a very poor investment. I need not enlarge on this point. The man who is to expound the Scriptures should be one of the best and brightest men in the whole community, and the people should pay enough to support a good man.

Please bear with me a little further when I suggest that the Electropoise people would never have found a hundred *ministers of the gospel* in our land to help sell their fraud, were it not true that there is a mistake somewhere. Dr. Wilford Hall, as you may remember, pushed his water-cure fraud mainly through ministers of the gospel—that is, people who had "Rev." attached to their names. I know, dear brothers of the clergy, there are many devoted and saintly men who are very poorly paid for their services. I know of some who have been promised a meager salary of considerably less than \$1000 a year, but who never got—at least not promptly—the amount subscribed. I do not know how many places there are where Christian people of all denominations unite to support a church and pay a minister. I mentioned one such I found in Florida. There are difficulties in the way that I confess I am not able to manage. We can get along with communion very well; but during a revival season, when new converts are to be added to the church, I confess I am not equal to the task of deciding how it should be done; but I have unbounded faith that the dear Savior, who invited us clearly and plainly to come to him with all difficulties of what-

cigar nature, will manage this one too, especially since it is only a question as to *how* and in what *manner* we shall come to him and bow at his feet, as we give him our lives and "crown him Lord of all."

## A SERMON TO BOYS AND GIRLS.

THE BOYS' BAD BARGAIN.

By W. T. Elsing.

A great many years ago twin brothers were born. I do not know whether their mother dressed them alike, as mothers frequently do now, but, although they may have worn the same kind of clothes, there never were twins who differed so much as these two boys. They were just as different as day is from night, or as light from darkness. One of the boys was very quiet. He was a shepherd; and at night, when he had brought the flock into the fold, he would go to his tent, kindle his fire, and cook his supper. But the other brother was very restless; he did not like walking quietly behind a flock of sheep, but was far more at home when on the chase. So he became a hunter, and went out from the tent every morning with the bow across his shoulder, and case full of arrows.

Jacob, the shepherd boy, would often run into his mother's tent with a pitcherful of milk, or a bundle of wool for her to spin into coats and dresses; therefore the mother loved him. Esau, the other brother, often came home, carrying on his shoulder not only his faithful bow but a good fat deer for his father.

In the country where these boys lived, there was a law that the first-born son should receive a double portion of his father's money. When the father died, the first-born son also received his father's blessing and other great honors. This was called the birthright, and belonged to Esau, the hunter.

One day Esau had been hunting all day, and had become very hungry in roaming through the fields for game. At last he came to his brother's tent. Jacob had his sheep in the fold, and had cooked some porridge of red bean meal. The whole tent was full of the delightful odor of the steaming porridge-pot. The hungry hunter said, "Give me of that red." He meant of that red porridge; but a hungry man uses few words. Jacob, who was very quiet and never in a hurry, but always ready to drive a sharp bargain, said:

"Esau, you know you were born a little before me, and, according to our law, the birthright is yours; but I'll tell you what I will do with you. If you will give me your birthright I will give you my porridge."

Esau said, "Well, I am going to starve any way. If I don't get something to eat, I may just as well sell the birthright, for the best birthright in the world is of no value to a dead man. Give me your porridge and I will give you my birthright."

But Jacob, who was in some ways a mighty mean boy, and who always looked out for the biggest end of a bargain, said, "You swear to me, that you will sell your birthright for the porridge."

Esau then made a solemn promise before God that he would stick to the bargain. So Jacob gave to Esau the porridge, and some bread and water.

After Esau had eaten he went away and fell asleep in his own tent; but, oh how sorry he was afterward that he had made such a bad bargain! Day and night, with tears and a sad heart, he tried to get the birthright back, but he failed. Esau has ever since been known as the boy who made a bad bargain. Esau made a bad bargain because he gave more than he received; and every boy who gives more than he receives makes a bad bargain. Esau has been dead nearly 4000 years; but his foolish bargain has never been forgotten.

But although the first Esau is dead, there are a good many boys who might with good right be called "Esau." Some of these boys are very popular, just like Esau; they take a great deal of interest in manly sports. There are many of them fine fellows, too, but they make bad bargains, and therefore we will call them "Esau."

### I.—THE SMOKING ESAU.

The boy who begins to smoke makes a bad bargain. We will say he gives a nickel for his first

cigar. Now, what does he get? A white, deathly face, an awfully sick stomach, and sometimes a good whipping from his mother. I think there is not a boy in America so foolish that he would not rather have a nice bright five-cent piece than a pale face, a sick stomach, and a whipping. So you see the boy makes a bad bargain with his first smoke. But, you say, it is not fair to judge by the first smoke. The boy will not always be sick, and his mother will not always object to his smoking. That is true. Let us, therefore, take not the first, but the one hundredth smoke. What does the boy now give for smoking? He gives not one but a good many five-cent pieces. It will all depend upon how much money he has. Suppose he is a poor boy, and spends only five cents each day until he is twenty-one. This makes 35 cents a week, \$18.20 a year, which, put in a bank at a low rate of interest, would become a sum of over \$275 by the time the boy is twenty-one. Now, what does the young smoker get for his \$275? He gets only one thing, and that is pleasure. There is not any other advantage in smoking; and the only question is, "Does it pay to acquire an appetite which is not natural, at so great a cost?"

"Ah! but," you say, "I get something else. I am in the fashion."

I do believe that you are not in the fashion with the majority of good people. If I should call on all the old smokers in America, and say, "Gentlemen, which boys do you admire most—those who smoke or those who do not smoke?" I am quite sure the majority of them would say, "Although we smoke ourselves, we like the boys best who do not smoke." The boys who do not smoke are looked upon by all sensible people as the best.

The smoking boy makes a bad bargain, because all good physicians will tell you that smoking is bad for a boy who is growing. To the boys who already smoke, and are not willing to give it up, let me say that cigarette-smoking is the worst thing you can do. The nicotine, or tobacco-oil, is a deadly poison; and if you are determined to smoke, the least dangerous way is to smoke a long clay pipe, which partly draws in the poison.

But smoking is a bad bargain, because, when you once begin it is hard to give it up. A little over three hundred and fifty years ago the only smokers in the world were the North American Indians. The tobacco-plant was first brought to Spain, and there it grew in the yards as an ornamental plant until a man named Nicolo Manardes said, "Tobacco is good as a medicine." Men all over Europe began to use it; but it was at first looked down upon by almost every government. Two hundred and fifty years ago the men who smoked in Russia had their noses cut off. In Turkey the Sultan beheaded smokers in the most cruel manner. In England, King James I. was very bitter against it. He said, "It is loathsome to the eyes, hateful to the nose, harmful to the brain, and dangerous to the lungs; and the stinking fumes resemble the smoke of the bottomless pit." But all the opposition of kings did no good. The habit was stronger than czars, sultans, or sword. The people kept on smoking. They liked it, and the habit grew stronger and stronger, until to-day almost every man in Persia and Turkey smokes. Millions in Europe smoke; and in Asia, not only the men but women, and even the girls, smoke.

A habit which, in three hundred years, spread over the whole world, must be fearfully strong. It is with smoking as it was with the threads with which the Lilliputians bound Gulliver. The story is so interesting I will tell it to you. Gulliver was a sailor and a great traveler. He had been in about every part of the world. One day he was wrecked on the shores of a strange land. All of the crew were drowned but Gulliver. He was very tired and wet, so he lay down on the warm sand and went to sleep. The people who lived on the island were very little, and were called Lilliputians. The largest were not as big as Gulliver's thumb. When they saw him, like a mountain, sleeping on the sand, they were frightened, but soon came nearer. They held a mass-meeting, and determined to take Gulliver prisoner. So they got ladders and ropes, and came to him. They put the ladders on the sides of his body, and climbed up. Then they carried thousands of threads across Gulliver's body, and drove little pegs into the sand to fasten the threads, so they worked a great many hours. Finally Gulliver woke up and tried to stir; but he was fastened so

securely he could do nothing. The little men shot thousands of small arrows at him, and they pricked like needles in his face. One of the little threads was no stronger than a cobweb; but many of them bound Gull ver so firmly that he could not get away. It is just so with the habit of smoking, and therefore I say the boy who begins to smoke runs a chance of losing his freedom, his money, and his health, which is also a bad bargain.

#### II—DRINKING ESAU.

If the boy who smokes makes a bad bargain, the boy who learns to drink makes a much worse one. Drinking is much older, more expensive, more dangerous, and more degrading than smoking. If all the money which is spent for strong drink in our country were divided equally among the different families, rich and poor, each family would receive \$90.00 a year. In the United States alone, 75,000 men die every year of drunkenness; 205 every day, one every seven minutes. The cup has killed far more people than the cannon. You all know how much sorrow and wretchedness are caused through strong drink. Many children are suffering this very day because their poor fathers learned to drink, and made the bad bargain years ago.

A great many years ago the Lacedemonians, a people of Greece, used to make their slaves drunk once a year. They brought these drunken men into a circus-ring that all the free children might see how disgusting a drunken man looked and acted, and that the children might never follow the example of the slaves.

Not long ago a poor drunken boy said he was not afraid to fight any man in the town. When he could get no one to fight with him, he went away to the railroad track. There the engineer saw him standing with his fists doubled up, ready to strike the engine. It was impossible to stop the express train quick enough, and the poor boy's body was crushed. He made a bad bargain; he gave his life for a drink. A drinker with inflammation in his eyes said, "Doctor, can you cure my eyes?" The doctor replied, "I can if you will stop drinking."

"Give up my drinks? Oh, no! Good-by, eyes," and he sold his eyes for a glass of whisky.

#### III.—THE SWEARING ESAU.

The boy who swears makes a terribly bad bargain. I can see how a hungry boy might be lead to steal a loaf of bread, if it were steal or starve, but I can not understand why any boy should ever swear. No one ever became any richer, wiser, or better for swearing. The biggest fool can swear as well as the wisest scholar. Swearing is hurtful to him who does it. It shocks all good people, and it grieves God. Swearing is the language of hell. The swearer is like a foolish fish who bits at a bare hook. Smoking, drinking, and swearing come to us like the Arab's camel. On a very cold night an Arab was sleeping in his tent, and the camel was on the outside. The camel woke the master up and said, "Master, it is very cold out here; may I please put my nose into the tent?"

"Yes," the Arab said, "You may put just your nose in."

"O master! it is so nice in your tent! won't you please let me put my head in too?"

After a while the master said, "Yes, put in your head."

Soon the camel pushed a little farther, and begged that he might put his shoulders in. This was also granted. Then without any other word the camel pushed in his whole body.

"It is very uncomfortable here," said the Arab. "Yes," said the camel. "It would be much more comfortable for me if you would go out and give me the whole tent."

Boys, the Arab made a bad bargain when he allowed the camel to put in his nose; and when we allow the first glass to touch our lips we make an awfully bad bargain with the old demon Alcohol.

With the crowd of business we have had during the past season I did not get over to see my neighbor Terry until well along in September. I said to myself several times, "Now, old fellow, first you know something will turn up that will make you feel sorry you have not kept track of what is going on over in Summit Co., especially at friend Terry's." When I got hold of the *Practical Farmer* for Sept. 11 I thought that very thing, for here is what I found. Let me say, first, that some college (agricultural) professor had been severely criticising Terry's teachings in regard to cutting potatoes to one eye, and Terry replies. In his reply he incidentally gives the result of an experiment made during the past season, and I clip as follows in regard to this experiment:

#### SEVENTY-FOUR HILLS FROM ONE TUBER.

Last May I took one medium-sized tuber and cut it into one-eye pieces, about such as we usually plant. Then I carefully cut each of these one-eye pieces into about six smaller pieces, in such a way as to leave a little point of the eye on each piece, as well as I could. The potato is a new one, not named, of strong vitality. Do not write and ask about it as it is not on the market yet. Mr. Wm. Henry Maule, the well-known seedsmen, sent me the potato. It was a fine-looking tuber, and took my fancy. So I thought I would raise as many from it as I reasonably could. It came after our crop was planted, and we had no ground plowed that was suitable. So after mowing off the clover I plowed two square rods of clover sod. This was a great mistake. The clover had pumped the water out of the subsoil pretty thoroughly. The ground was too dry. I wished a hundred times that I had known beforehand, and plowed the land early, and kept surface harrowed. And I would have put half a ton of manure on last fall, too, if I had known it. Then I might have done something. Well, I got the potatoes started, although it was too dry for a time. Now we are getting plenty of rain. There are 74 hills growing in about two square rods. The hills are 33 inches apart each way. They now cover the ground about as well as you often see it done. I think any grower would say there were tons enough on the ground. They are all good. Eighty tubers would plant an acre. They are not ready to dig yet, so I will not say any thing about the yield, but we have the plants. Only about one-sixth of an eye was planted to a hill! I could have carried it further and got more hills, but my wife said: "What is the use? only experts will believe what you have done now." So I quit. Of course, these very small pieces required more care in cutting, and finer soil, and better attention, than whole-eye pieces would, and far more than whole tubers used for seed would. This fine cutting is not practical at all, except when you want to get all you can from a few tubers. But it helps to establish my point, and very greatly, too, that I can make all the eyes grow, and get good thrifty plants from all of them, practically.

After reading the above, you may be sure I was not long in getting on my wheel and going over to see the 74 hills grown from one tuber. Every hill was perfect, and the single vine in each hill was remarkably strong and rank. Friend T. put his hand into one of the hills and took out two tubers weighing, I should judge, a pound or more, but they were then not quite done growing. I estimated there would be about a barrel of potatoes as the result of that one tuber. The potatoes have now been dug, and, if I remember, there

I never could raise enough potatoes to do us before I got your potato-book. I planted 2 bushels then. Now I have to plant only half a bushel, and raise more than enough to do us. In 1889 I raised 48 measured bushels from ½ bushel planted and cultivated according to your book. Nearly every one laughed at me for giving such shallow cultivation—said that I only scratched around; but they did not laugh at the yield.  
Morgan, Ky., July 28. J. P. MOORE.

was not quite a barrel, but pretty nearly. I at once wrote to Maule, asking the price of a single tuber; but he told me there would be none for sale until the year 1899. The season of 1898 will be devoted to increasing the stock; but I finally did get a tuber to experiment with in the greenhouse, with the understanding that the stock belongs entirely to Wm. Henry Maule. I am going to work with this one tuber at once, and increase it by means of the jadoo fiber and greenhouse all I possibly can until time to plant potatoes next spring. Oct. 1, 1898, Maule is to pay me a reasonable price per bushel for as many potatoes as I succeed in growing in just one year. This particular new potato seems to possess earliness and vitality; but we can not just now tell whether it is Terry's skill or the remarkable productiveness of the potato—perhaps both.

Now, then, friends, has anybody ever tried the experiment of seeing how far one potato could be made to increase in just one year by propagating it during winter as florists grow geraniums, coleis, and other similar plants? I will try to report progress to you as we go along. The worst trouble I anticipate is in getting the potato to sprout and grow so soon after it has been dug.

#### A REFRESHING CONTRAST IN THE WAY OF TREE AND PLANT CATALOGS.

In Lovett's pamphlet for autumn of 1897 we found the following in regard to two of our new friends:

##### GOLDEN MAYBERRY.

This unique fruit may be all that is claimed for it, but candor compels us to state that we are growing impatient to see for ourselves what it is actually like. We have now had it for three years; and, although the bushes grow well, they have as yet failed to produce any fruit, and we hesitate to longer publish the descriptions of the originator and disseminator until we know *positively* it is what it is claimed to be.

##### STRAWBERRY-RASPBERRY.

From an intimate acquaintance with this berry we are convinced it is not a hybrid of the strawberry and the raspberry, as claimed, but it is a true raspberry of herbaceous habit (the top dying down and the root surviving as with the paonia and many cultivated species of flowering plants), and has no strawberry blood in it whatever. It has proved to be a wonderful grower, always clean and vigorous, with a mass of deep-green foliage; and although it suckers immoderately it is extremely hardy, and is prolific in bearing for a period of some ten or twelve weeks—from early in July until frost. The berries are of enormous size, of the richest shade of bright crimson imaginable, and are in very truth the most exquisitely beautiful of any berry we ever looked upon; but, alas! it is sadly deficient in flavor. Some have compared it to dried apples, others to a sweet orange sucked dry. Seriously, it is decidedly insipid as a dessert fruit, but, strange as it may seem, when cooked it is rich, sweet, and good.

The above really rejoices my heart. The Lovett people have finally tested these things on their own ground, and have come out square and honest about it. Their experience is exactly like my own. The Logan berry, however, promises to be something of real value. On our grounds it has not as yet borne fruit enough, but it will, perhaps, when it gets older.

#### GARDENING FOR THE LATTER PART OF OCTOBER.

In addition to what was said in our last issue, I would again remark that now is the

time to commence gardening under glass. If you have valuable varieties of strawberries, you can keep them putting out runners, and increasing, clear on till Christmas, by the use of a few sash. But let me suggest where you are in danger of making a mistake. Shelter your plants with the sashes whenever there is a hard freeze. Even quite a frost will not injure strawberries at all. When the ground begins to freeze, however, so as to be hard, then put on the sash. But do not cover the plants up during a snowstorm. Strawberries seem to rejoice in being covered with snow. I have actually seen harm done by leaving the sashes on so as to keep *off* the snow during a severe freeze. Strawberries and other hardy plants are better off with a covering of snow than with sashes; and the same will apply to lettuce where it is sufficiently hardened—say cold-frame lettuce-plants. Whenever there is severe freezing, however, without any snow, then have your sashes on. Keeping this in mind will not only save you labor in handling sashes, but it will really save your plants. The snow is nature's covering and protection. Permit me to say right here that we have put in some new and expensive machinery for making an improved article of hot-bed sash, and I believe our prices are considerably below those of good substantial sash anywhere else. See prices in Special Notices.

Our fall catalog—that is, our usual catalog with prices changed according to the present date (so far as we can fix prices at this time), will be ready to mail to applicants soon after this reaches you.

#### OUR BRIEF VISIT TO T. GREINER, LA SALLE, NIAGARA CO., N. Y.

*Friend Root:*—I have just been reading what you say about your visit here page 733. It seems to me you have "put it on a little thick." In fact, I knew that, in the hurry of summer's work, and in consequence of my being busy otherwise, the place had a neglected appearance; but had I been fortunate enough to be at home when you came, I could have shown you many things of interest that the unguided visitor could not possibly have found or discovered. The best sights you might have seen are nearly half a mile away from the home place.

In regard to that new onion which your printer named "Garganus," let me state that it is Burpee's Gibraltar, a most excellent variety for fancy trade, equal to the imported Spanish, nearly as large, as mild, and of a light straw color; must be sold promptly, as it does not seem to be a good keeper, especially in a wet season like this. I hope that next year we shall be able to procure seed, at least by the ounce; for the past three years we could get it only by the packet, at rather high prices. As to the coal-ash bed, I believe a good layer of manure *under* the coal ashes was responsible for the great thrift of the plants more than any thing else.

T. GREINER.

La Salle, N. Y., Oct. 8.

Friend G., I know how it is from my own experience. Sometimes visitors whom I very much wanted to see have gone over our grounds and entirely overlooked the most important things because I was not there to give particulars. Many thanks for correcting me about that onion. Since you mention it, I remember now that friend Weckesser did call it Gibraltar instead of Garganus; and, by the way, we will try to have some of the Gibraltar for sale, at least in packets, another season.

**Books for Bee-keepers and Others.**

Any of these books on which postage is not given will be forwarded by mail, postpaid, on receipt of price. In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the bookseller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. I very much desire that those who favor me with their patronage shall not be disappointed, and therefore I am going to try to prevent it by mentioning all the faults, so far as I can, that the purchaser may know what he is getting. In the following list, books that I approve I have marked with a †; books that I especially approve, \*; those that are not up to times, ‡; books that contain but little matter for the price, large type, and much space between the lines, †. **Foreign.** § The bee-books are all good

**BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.**

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice, that you can judge of the size of the books very well by the amount required for postage on each.

|   |   |      |
|---|---|------|
| 8   | Bible, good print, neatly bound.....  | 20   |
| 10  | Bunyan's Pilgrim's Progress**.....  | 50   |
| 20  | Illustrated Pilgrim's Progress**.....   | 75   |
| This is a large book of 425 pages and 175 illustrations, and would usually be called a \$2.00 book. A splendid book to present to children. Sold in gilt edge for 26c more. |   |      |
| 6   | First Steps for Little Feet. By the author of the Story of the Bible. A better book for young children can not be found in the whole round of literature, and at the same time there can hardly be found a more attractive book. Beautifully bound, and fully illustrated. Price 15c. Two copies will be sold for 75 cents. Postage six cents each. |      |
| 5   | Harmony of the Gospels.....   | 35   |
| 3   | John Ploughman's Talks and Pictures, by Rev. C. H. Spurgeon.....  | 10   |
| 1   | Gospel Hymns, consolidated Nos. 1, 2, 3, and 4, words only, cloth, 10 c; paper.....   | 05   |
| 2   | Same, board covers.....   | 20   |
| 5   | Same, words and music, small type, board covers.....  | 45   |
| 10  | Same, words and music, board covers.....  | 75   |
| 3   | New Testament in pretty flexible covers.....  | 05   |
| 5   | New Testament, new version, paper covers.....   | 10   |
| 5   | Robinson Crusoe, paper cover.....   | 10   |
| 4   | Stepping Heavenward**.....  | 18   |
| 15  | Story of the Bible**.....   | 100  |
| A large book of 700 pages, and 274 illustrations. Will be read by almost every child.   |   |      |
| 1   | "The Life of Trust," by Geo. Muller**.....  | 1 25 |
| 5   | Tobacco Manual**.....   | 45   |
| This is a nice book that will be sure to be read, if left around where the boys get hold of it, and any boy that reads it will be pretty safe from the tobacco habit.       |   |      |

**BOOKS ESPECIALLY FOR BEE-KEEPERS.**

| 5   | A B C of Carp Culture, by Geo. Finley.....        | 35 |
| 5   | A B C of Strawberry Culture** By T. B. Terry..... | 35 |
| Probably the leading book of the world on strawberries.   |   |    |
| 3   | A B C of Potato Culture, Terry**.....             | 35 |
| This is T. B. Terry's first and most masterly work. The book has had an enormous sale, and has been reprinted in foreign languages. When we are thoroughly conversant with Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. It has 48 pages and 22 illustrations. |   |    |

|   |  |      |
|---|--|------|
| [Barn Plans and Out-Buildings*.....   | 1 50   |      |
| [Canary Birds, Paper.....   | 50   |      |
| 2   | [Care for Profit, by T. Greiner**.....                       | 25   |
| This is a really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once, without any assistance except from the book.   |  |      |
| 10  | [Draining for Profit and Health, Warrington.....             | 1 35 |
| This is, perhaps, the most systematic, comprehensive, and thorough work on grape culture now in print; in fact friend Fuller here tells us how, by easy steps, to make any grapevine come into the work, and make a pleasant, orderly appearance; and he makes it as attractive as a piece of fiction. It is the best part of it is, that you get great crops of beautiful grapes during almost any kind of season. We have tested the system, and know whereof we speak. |  |      |
| 8   | [Domestic Economy, by I. H. Mayer, M. D.**                   | 30   |
| This book ought to save at least the money it costs, each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life-study. The regular price of the book is \$1.00; but by taking a large lot of them we are enabled to make the price only 30c.   |  |      |
| 10  | [Farming for Boys*.....                                      | 1 15 |
| This is one of Joseph Harris' happiest productions, and it seems to me that it ought to make farm-life fascinating to any boy who has any sort of taste for gardening.  |  |      |
| 7   | [Farm, Gardening, and Seed-Growing**.....                    | 90   |
| This is by Francis Brill, the veteran seed-grower, and is the only book on gardening of its kind, that you get that tells how market-gardeners and seed-growers raise and harvest their own seeds. It has 166 pages.  |  |      |
| 10  | [Fuller's Grape Culturist*.....                              | 1 15 |
| 12  | [Gardening for Pleasure, Henderson*.....                     | 1 35 |
| While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part; and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your gardens in this way, that the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.  |  |      |
| 12  | [Gardening for Profit**.....                                 | 1 35 |
| The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making modern gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments, if you can get but one book, let it be the above. It has 372 pages and 162 cuts.   |  |      |
| 8   | [Gardening for Young and Old, Harris**.....                  | 1 25 |
| This is by Joseph Harris, the happiest of all. Although it goes over the same ground, occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.                |  |      |
| 10  | [Greenhouse Construction, by Prof. Taft**                    | 1 15 |
| This book is of recent publication, and is as full and complete in regard to the building of all glass structures as the new work in regard to their management by one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.   |  |      |
| 5   | [Garden and Farm Topics, Henderson**.....                    | 60   |
| 5   | [Gray's School and Field Book of Botany.....                 | 1 80 |
| 5   | [Gregory on Cabbages; paper*.....                            | 20   |
| 5   | [Gregory on Squashes; paper*.....                            | 20   |
| 5   | [Gregory on Onions; paper*.....                              | 20   |
| The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.  |  |      |
| 15  | [How to Make the Garden Pay.**.....                          | 1 35 |
| By T. Greiner. This is a new book, just out, and it gives the most explicit and direct hints as to how to make money out of any book in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses or glass structures of any kind for the growth of plants, can not afford to be without the book.   |  |      |
| 10  | [Handbook for Lumbermen.....                                 | 05   |
| 10  | [Household Conveniences.....                                 | 1 40 |
| 2   | [How to Propagate and Grow Fruit, Green*.....                | 10   |
| 10  | [How to Get Well and Keep Well.....                          | 90   |
| An exposition of the Salisbury system of curing disease by the "lean meat diet."  |  |      |
| 2   | [Injurious Insects, Cook.....                                | 10   |
| 10  | [Irrigation for the Farm, Garden, and Orchard, Stewart*..... | 1 10 |
| This book, so far as I am informed, is almost the only work on this matter that is attracting so much interest, especially recently. Use of the water as much as we might expect it to take the place of rain, during our great droughts, is the great problem before us at the present day. The book has 274 pages and 142 cuts.   |  |      |
| 7   | [Market-gardening and Farm Notes, by Burnett Landreth.....   | 75   |
| The Landreth is the pioneer seedsman of America; and the book is worth as fully as much as we might expect it to be. I think I received hints from it worth the price, before it had been in my hands fifteen minutes. It is exceedingly practical, and tells what has been done and what is BEING done, more than it discourses on theory.   |  |      |

3 | Maple Sugar and the Sugar-bush\*\* ..... 35  
 By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, one of the finest sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written in Prof. Cook's happy style, combining wholesome moral lessons with the latest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses wants the sugar-book. It has 42 pages and 35 cuts.

4 | Peabody's Webster's Dictionary ..... 10  
 Over 30,000 words and 250 Illustrations

5 | Manures; How to Make and How to Use them; In paper covers..... 30

6 | The Same In cloth covers ..... 65  
 Covering the whole matter, and discussing every thing to be found on the farm, refuse from factories, mineral fertilizers from mines, etc. It is a complete summing up of the whole matter. It is written by F. W. Semper.

3 | Onions for Profit\*\* ..... 40  
 Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written in the enthusiastic and interesting style that characterizes its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

1 | Our Farming, by T. B. Terry\*\* ..... 1 50  
 In which he tells "how we have made a run-down farm bring both profit and pleasure."

This is a large book, 6x9 inches, 367 pages, quite fully illustrated. It is Terry's first large book; and while it touches on the topics treated in his smaller handbooks, it is sufficiently different so that no one will complain of repetition, even if he has read all of Terry's little books. It is, in fact, all that the brightest and most practical book on farming before the world at the present day. The price is \$2.00 postpaid; or clubbed with GLEANINGS for 2.50. Those who are already subscribers to GLEANINGS may have it postpaid by sending us 1.50 more. We are sure it will be worth many times its cost that we are not afraid to offer to take it back if any one feels he has not got his money's worth after he has read it. If ordered by express or freight with other goods, 10c less.

1 | Poultry for Pleasure and Profit\*\* ..... 10

8 | Practical Foultryculture, Henderson\* ..... 1 10

10 | Profits in Poultry\* ..... 75

2 | Practical Turkey-Raising ..... 10  
 By Fanny Fil. This is a 25-cent book which we offer for 10 cts.; postage, 2 cts.

2 | Rats; How to Rid Farms and Buildings of their Character\*\* ..... 15

1 | Silk and the Silkworm ..... 10

10 | Small-Fruit Culturist, Fuller ..... 1 10

10 | Success in Market-Gardening\* ..... 90  
 This is a new book by a real-life, enterprising, successful market-gardener who lives in Arlington, a suburb of Boston, Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drought threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.

10 | Talks on Manures\* ..... 1 35  
 This book, by Joseph Harris is, perhaps, the most comprehensive one we have on the subject, and the whole matter is considered by an able writer. It contains 366 pages.

7 | Ten Acres Enough ..... 75

2 | The Carpenter's Steel Square and its Uses. .... 15

10 | The New Agriculture; or, the Waters Led Captive (a \$1.50 book) ..... 40

2 | Treatise on the Horse and his Diseases ..... 10

5 | Tile Drainage, by W. I. Chamberlain ..... 35  
 Fully illustrated, containing every thing of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs, to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in planting.

3 | Tomato Culture ..... 35  
 In three parts. Part first—by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. Cummins, of Conneaut, O., treats of tomato culture especially for canning factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South.

3 | Vegetables under Glass, by H. A. Dreer\*\* ..... 20  
 This is a new book by a veteran in the work, full of illustrations from real life, and by all odds, the most valuable book we have ever had for such a small price.

3 | Winter Care of Horses and Cattle ..... 35  
 This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages and 4 cuts.

3 | Wood's Common Objects of the Microscope\*\* ..... 47

8 | What to Do and How to be Happy While Doing It, by A. I. Root ..... 50

THE A. I. ROOT CO., MEDINA, O.

# Dovetailed Hives,

Sections, Extractors, Smokers, and every thing a bee-keeper wants. **Honest goods at close honest prices.** 60-page catalogue free.

**J. M. JENKINS, Wetumpka, Ala.**

**25 Cts. PER YEAR!**

for the best agricultural and stock-breeders' paper published,

**Stuart's Agriculturist.**

Agents wanted! Bicycles, etc., free. Address

Liberal Advances Made on Consignments. Wholesale Dealers and Commission Merchants. Established 1875.

**SWEET-CLOVER SEED** in the hull, raised this season, 1897, at 4 cts. per pound. Address **JOSEPH SHAW, Box 64, Strong City, Kan.**

In writing advertisers mention this paper.

#### MAPLE SUGAR.

We have on hand about 150 lbs. of No. 1; 450 lbs. of No. 2, and 100 lbs. of No. 3. We offer this in small lots at 9, 8c, and 7c per lb. respectively for the three grades; 50-lb. lots at  $\frac{1}{2}$ c per lb. less; barrel lots of about 300 lbs. at about at 1c per lb. less.

We have also a few gallons of good clear syrup, not first run, at 85c per gal.; 5-gallon lots at 90c. We can also get on short notice first-grade syrup at about 90c per gallon.

#### HONEY MARKET.

Sales of both comb and extracted honey have been very good so far this month. Prices remain the same as quoted in Oct. 1st issue. We are handling more than we did last year, and shall be glad to hear from those who have honey to offer. In writing, please state how much you have, stating amount of each grade; also how it is put up, etc., to save correspondence. Also state lowest price you will take for your crop, and give us freight rate to Medina if possible. We are especially in need of light extracted just now.

#### GREENHOUSE AND COLD-FRAME SASH.

Having taken a job requiring a large amount of mortising, we have added to our equipment of machinery a chain mortiser, and are now prepared to furnish greenhouse and cold-frame sash, made in the ordinary way with mortise and tenons. If these sash are shipped in the flat (K. D.) it will not be quite so easy to put them together as the rabbeted style we have been making. After they are well put together they will be better, stronger, and more durable. If shipped put together the freight is more than it is when shipped in flat. Sash put together go at first-class rate of freight, either with or without glass. We will furnish these sash in flat as before at same price; viz., 70c each; \$3.25 for 5, or \$6.00 for 10 sash, 3 feet 4 inches wide by 6 feet long for 4 rows of 8-inch glass, or three rows of 11-inch glass. Sash put together will be 10c each extra. Glass included will add another dollar to the price of the sash put up.

#### SECOND-HAND ENGINES AND DYNAMO FOR SALE.

We have grown beyond the capacity of our 75-light dynamo to furnish us with adequate light, and are compelled to put in a larger machine. In doing so we have decided that it will be economy to put in a machine large enough to furnish electricity to run by electric motors our printing machinery and machine-shop, instead of using our present method of carrying steam long distances in pipes and running several small steam-engines. These changes necessitate the throwing out of our 75-light dynamo and two small engines, and possibly two more a little later.

We offer for \$75.00 a 75-light, 88-volt, Brush dynamo. This machine cost us about \$400 seven years ago, and has been doing us good service ever since, and would continue to do so if it were large enough. It is a bargain. Further particulars to those interested, on application.

One 7½-H. P. upright engine, which has been running our presses and other machinery in our printing department. We offer this for \$85.00. This size, when new, sold for \$125, and this has had the best of care, and for service is as good as new. We also offer a 10-H. P. engine for \$100; same general description. This is just the right size for running the dynamo.

### Special Notices in the Line of Gardening, etc.

By A. I. Root.

#### SENDING MONEY LOOSE IN A LETTER.

I would urge all the friends in remitting to use a bank draft, express money order, or postoffice money order for any amount over \$1.00. If you can not get either of the above, then have the letter registered, which costs only 8 cents. I am very sorry to say that, for six months past, there has been considerable evidence to the effect that somebody is tampering with

the mails. We have promptly reported to the Department at Washington, and they have been making investigations for six months. Notwithstanding this, every little while we are pained to hear of losses. There have been more for the past season than for several years past, but we hope to be able soon to get hold of the culprit. Please read again our instructions for sending money, that go out with every catalog.

#### PRICES OF SEED POTATOES FOR 1898.

I suppose nobody can tell just how very much about what potatoes will be worth next spring; but from all the facts I can gather from different localities all over the United States it is pretty certain that prices will advance rather than decrease. And, still further, I have not been able to find prices anywhere as low as I gave in the table in our issue for Sept. 15, page 684. In fact, several kinds are sold out, or nearly so, and we can not replace them at the prices offered there. Until further notice the prices will be as in the table below:

#### SCALE OF PRICES ON FOLLOWING POTATOES.

| NAME                   | 1 lb. by mail. |          | 3 lbs. by mail. |          | $\frac{1}{2}$ peck. | Peck. | $\frac{1}{2}$ bu.-bel. | Bus.-bel. | Barrel—11 pk. |
|------------------------|----------------|----------|-----------------|----------|---------------------|-------|------------------------|-----------|---------------|
|                        | by mail.       | by mail. | by mail.        | by mail. |                     |       |                        |           |               |
| White Bliss Triumph    | 18             | 40       | 25              | 40       | 7                   | 1.25  | 3.00                   |           |               |

| Manum's Enormous       | 30             | 75       | 30              | 50       | 85                  | 1.50  | 3.50                   |           |               |
| New Craig              | 18             | 40       | 25              | 40       | 75                  | 1.25  | 3.00                   |           |               |

These potatoes are wanted for table use, and may be allowed to make our own selection of such kinds as we have most of, we will make a special price of 75 cts. a bushel or \$2.00 a barrel. This latter price is for an immediate order. These table potatoes will probably be either the State of Maine, Empire State, or Burbank. We can still furnish seconds at half prices given in the table, of all except White Bliss, Early Northern, and Burpee's Extra Early. We shall put into the seconds badly shaped potatoes, and those that have been cut in digging, and those that are somewhat scabby, but, of course, nothing that is not in good order for shipping. I would urge the friends to have their potatoes shipped at once while there is no danger of frost. In fact, I will guarantee them to reach you free from damage by frost if the order reaches us before Nov. 15.

Permit me to call attention to our second-sized Freemans grown by T. B. Terry. The larger ones are just the thing for a baking potato for table use; and at only \$1.50 per barrel they are a bargain. We call attention to it now because, for several years past, Terry's second-sized Freemans have been closed out so that a good many were disappointed by getting in their orders late.

We have also made arrangements to furnish the Bovee potatoes, but can not at present state prices, further than to say that ours will be as low as those of any responsible dealer. Peter Henderson claims that the Bovee is earlier than the Early Ohio, and very much more productive. From the few we have grown on our own grounds, we are inclined to think he may be correct in both particulars.

#### "EVERY THING IN THE BEE-LINE WORTH PRINTING."

On page 721 of our Oct. 1st issue our old friend Henry Alley was permitted to say in the Kind Words department that GLEANINGS contains about every thing in the bee-line worth printing. Of course, he gave this as his opinion. I have said once before that I did not mean to let anything of that kind appear in print again. No doubt friend Alley meant exactly what he said; but it was in a private communication, and not intended to be put into a public journal. Had the writer not been off on one of his wheelrins when said pages were made up, there would have been at least a modification of that kind word, for it is certainly not true. Neither Ernest nor myself believe it, and it would be unkind and discourteous to the editors of other bee-journals to even insinuate that ours is the best one of the lot.—A. I. R.

On account of quarantine restrictions, the South Texas Bee-keepers' Association, which was to meet at the Atchley place the first Wednesday and Thursday in November, has been postponed indefinitely. No public gatherings are allowed along the coast country on account of the danger of yellow fever.

**FOR SALE**.—25 Sash, glazed, 3½ x 8 ft., x 2 inch check, glass 12 x 12; also 12 sash, regular make, 3x4 ft. 6 in. x 1½; about 1000 ft. 12 x 12 glass, also sash-bars for same. A lot of pipe ½ in., 1 in., 1½ in., and some 2 and 3 in.; also a lot of pots, 4, 4½, 5, and 6 in. Will sell for one-half price of new.

J. S. WARNER, Medina, Ohio.

## MONEY-MAKING QUEENS.

Here I am, with 300 tested and untested queens to sell or exchange for water-white or dark-amber honey, or for cash at the following prices: Untested, 1 for 10c, 5 for \$2.75, 10 for \$5.00; tested, 1 for \$1.30, 5 for \$6.25, 10 for \$12.00. These queens are bred from my best honey-gatherers, seven years careful breeding.

B. J. COLE, Latonia, Wash.

### What They Say about the Pouder Honey-jars.

Walter S. Ponder, Indianapolis, Ind.:

Dear Sir:—According to our experience the Pouder Honey-jars come nearer to the general demand of the producer than any other package for extracted honey that we have ever seen. They are unexcelled for their neat and attractive appearance, and the loss in transit with your method of crating is almost nothing. If producers would use them more, instead of shipping their honey by the barrel, they could establish a home market for their product and greatly increase their profits. Yours, T. A. DANIEL & BRO., Wewahitchka, Fla.

500 Young Ferrets now ready

to ship. Send for free price list to

N. A. KNAPP.

Rochester, - - - - - Ohio.

### WINTER CASES FOR PENNSYLVANIA!

Root's goods at Root's prices. Send for catalogue.

PROTHERO & ROLD, DuBois, Pa.

### Wants and Exchange Department.

**WANTED**.—Position as apprentice in apiaary, by young man; high-school education; some experience with bees. T. F. MARTIN, Greensburg, Pa.

**WANTED**.—To exchange a fine coon hound, a fine young bird dog, and an English bull pup. I can use a good watch, gun, or anything in the photograph line. A photograph of either dog can be sent to any address for three 2c stamps. W. S. BRILLHART, Oakwood, Paulding Co., Ohio.

**WHAT** will you offer for one b-flat cornet and case, also one e-flat alto, good instruments, practically new? Address Box 321, Clifton, New York.

**WANTED**.—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules. ANTHONY OPP, Helena, Ark.

**WANTED**.—To exchange 28 new volumes Encyclopedia Britannica for honey. O. H. HYATT, Shenandoah, Page Co., Iowa.

**WANTED**.—To exchange 16-section non-drip cases at Root's prices, laid down at your station, for fancy comb honey at prices to suit the times. Also 2d-hand 60-lb. cans, 2 in a case, valued at 25 cts per can, freight paid, for gilt-edged extracted honey in 60-pound cans. Special price on quantity lots. B. WALKER, Evart, Mich., or 511 Van Buren St., Chicago.

### KIND WORDS FROM OUR CUSTOMERS.

You are doing a good thing by clipping bees before shipping. E. D. HOWELL, New Hampton, N. Y., Aug. 26.

My advertisement in GLEANINGS has brought me a good trade this season, and I have had a good honey crop. I have taken 3000 lbs. from 43 hives up to date, and shall get some surplus yet. J. D. GIVENS, Lisbon, Texas, Sept. 8.

## Honey Column.

### CITY MARKETS.

**MILWAUKEE.**—This market for honey keeps pace with any other in values for either comb or extracted. The supply is fair and the demand is only moderate, yet we feel confident that, as the cool weather comes and fruit season passes away, honey will have its share of attention. We will quote 1-lb. sections, white, 12@13; dark, 8@10; extracted, in barrels, kegs, and pails, white, 5½@6; dark, 4½; beeswax, 26@27.

A. V. BISHOP,  
Milwaukee, Wis.

**ALBANY.**—Fancy white pound combs selling at 12@13; No. 1 white, 10@12; buckwheat and mixed, 8@9; dark extracted, 4@4½; with no great demand for the latter. Would advise consignors to ship by freight, using shipping-cases with handles to carry, and thus avoid the risk of breakage.

CHAS. McCULLOCH & Co.,  
Albany, N. Y.

**DETROIT.**—Best comb honey, 11@12; other grades, 9@10½; extracted white, 5@5½; dark, 4@4½; beeswax, 25@26.

M. H. HUNT, Bell Branch, Mich.

**CINCINNATI.**—There is no change in our honey market since our last. We quote 10@10c as the range of prices for choice white comb honey, and 3½@6 for extracted honey, according to quality. Demand is exceedingly slow since the beginning of September. Beeswax is in good demand at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,  
Cincinnati, O.

**COLUMBUS.**—Fancy white clover, 12½@13; No. 1, 11@11½. We are in the market for white comb honey in any quantity.

THE COLUMBUS COMMISSION & STORAGE CO.,  
408-413 N. High St., Columbus, O.

**MINNEAPOLIS.**—Fancy white-clover comb, 10@11; best extracted, 5½@5½; other grades accordingly. Good time to ship to this market.

S. H. HALL & Co.,  
Minneapolis, Minn.

**PHILADELPHIA.**—Fancy comb, 13@14; No. 1 white, 12; fancy amber, 10; No. 1 amber, 9; fancy dark, 8; No. 1 dark, 7; white extracted, 5@6; amber, 5; dark, 4@4½; beeswax, 26@27. Honey market very active; trade booming, bright prospects.

W. M. A. SELSER,  
10 Vine St., Philadelphia, Pa.

**ST. LOUIS.**—We quote white comb honey 11@12; amber, 9@10; dark, 7@8; extracted white, 5½@6; light amber 4½@5; dark, 4@4½; beeswax, choice yellow, 26; prime, 25@25½; dark, half price.

WESTCOTT COMMISSION CO.,  
213 Market St., St. Louis, Mo.

**BUFFALO.**—Will quote prices as follows: Fancy white comb, 12; No. 1, 10@11; No. 2, 8½@9; buckwheat, 7@8; extracted white, 5@6; dark, 4@5; beeswax, 25@28, demand good; Buffalo usually is a good wax market. Honey has been selling slow, due partly to warm weather.

W. C. TOWNSEND,  
Buffalo, N. Y.

**KANSAS CITY.**—The receipts of comb are large; extracted, light. We quote fancy white comb, 12; No. 1, 10@11; amber, 8@10; extracted white, 5½@6; amber, 4@5; beeswax, 22@24.

C. C. CLEMONS & Co.,  
Kansas City, Mo.

**NEW YORK.**—During the past two weeks the market has not been so active, on account of the warm weather, we suppose. When cooler weather sets in for good, we expect a more active demand again. We quote fancy white, 12; No. 1, 10@11; amber, 9@10; light-wheat, 8@9; extracted Calif. white, 5@5½. Calif. light-amber, 4½@5; white clover and basswood, 5; buckwheat, 4; southern, in barrels, 50c per gal. and in good demand now; beeswax firm and in good demand at 26@27.

HILDRETH BROS. & SEGELKEN,  
120-122 W. Broadway, New York.

**CLEVELAND.**—The demand for honey is increasing, and believe will continue as the weather gets colder. We would advise shipping white honey, but dark is not moving sufficiently to encourage shipments. We quote fancy white, 12½@13; No. 1 white, 11@12; fancy amber, 9@10; No. 1 amber, 8; fancy dark, 7; No. 1 dark, 6; white extracted, 6@6½; amber, 5@5½; beeswax, 26@30.

A. B. WILLIAMS & Co.,  
Oct. 19. 80-82 Broadway, Cleveland, Ohio.

**CHICAGO.**—Fancy white comb honey, 11@12; good grades of honey, but travel-stained or irregular, 10; amber and buckwheat, 7@9; extracted white, 5@6; according to body, flavor, and package; dark and amber, 4@5; beeswax, 26@27, and sells readily.

R. A. BURNETT & Co.,  
Oct. 19. 163 South Water St., Chicago, Ill.

**DENVER.**—It is a hard matter for us to quote our honey market. Prices are still very low, the trade being supplied with honey from the farmers. We can quote comb honey at 10; No. 1 white extracted at 5. There is little or no demand for second grade, the best grade being so low.

R. K. & J. C. FRISBEE,  
Oct. 22. Lock box 101, Denver, Col.

**BOSTON.**—We quote you our honey market as follows: Fancy white, 13; No. 1 white, 11@12; fancy amber, 10; white extracted, 6@7; amber, 5@5½; beeswax, 26.

BLAKE, SCOTT & LEE,  
Oct. 22. Boston, Mass.

**SPRINGFIELD.**—Fancy white clover, 12c; choice white clover, 10; no buckwheat in.

PERKINS & HATCH,  
Oct. 7. Springfield, Mass.

**FOR SALE.**—25 bbls. extracted pure white-clover honey, very light in color, and of finest quality; at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

**FOR SALE.**—Alfalfa honey, light amber, in carload lots. 3¼ cts. per lb.; sample, 10 cts.

JOHN NIPPERT, Box 1651, Phoenix, Arizona.

**FOR SALE.**—Buckwheat extracted in 50 and 210 lb. packages f. o. b. for 4¼c a lb.

W. LAMAR COGGSHALL, West Groton, N. Y.

**WANTED.**—Shipments of comb and extracted honey. Can dispose of several hundred pounds of first and second grades. Can give good reference. Write me what you have and the price asked before making shipment.

D. N. KITCHEN, Black Lick, Ohio.

**FOR SALE.**—Tons of honey, comb, at 7 to 12c per lb. Include stamps for samples of extracted at 4 to 6c, in 100-lb. kegs, f. o. b.

N. L. STEVENS, Venice, N. Y.

**FOR SALE.**—Pure honey.—Clover, extracted, 6½ cts. per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City.

**FOR SALE.**—Good extracted white-clover honey and heartsease and Spanish needle. Either, price 5c per lb., 60-lb. cans, 2 in a case. Send stamps for samples.

JNO. A. THORNTON, Lima, Ills.

## Clover Seed Wanted.

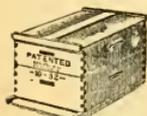

Parties in the West having alsike, red, or white-clover seed to sell may please make offers. We wish a few more choice lots of each. Address

Jos. Nysewander, Des Moines, Iowa.

# The Review at Reduced Rates.

The **Bee-keepers' Review** is \$1.00 a year, but, for the sake of getting it into new hands, and being able to begin the year with a large list, I will, until Jan. 1st, send free to each *new* subscriber, a copy of "Advanced Bee Culture," a 50-cent book of nearly 100 pages, that gives briefly but clearly the best methods of management from the time the bees are put into the cellar in the fall until they are again ready for winter—32 chapters in all. Those who prefer can have, instead of the book, 12 back numbers of the **Review**, the selection to be mine, but no two numbers alike. All who send \$1.00 now will receive the last four issues of this year free, and the **Review** will be sent until the end of 1898. If not acquainted with the **Review**, send 10 cents for three late but different issues.

W. Z. HUTCHINSON, Flint, Mich.

# \$100

Given as **BOUNTIES** to purchasers of the improved Danz. Hives and Sections. For particulars see p. 61, of my book, "**Facts about Bees.**" Sent **Free** for 2-cent stamp. Address  
**F. DANZENBAKER, Washington, D. C.**

**The A. I. Root Co.'s Goods At Their Prices.**  
 Including their discounts for goods wanted for use another season. It will pay you to send me list of goods wanted.  
**M. H. HUNT, Bell Branch, Mich.**  
 Cash for beeswax.

Philadelphia Office of  
**THE A. I. ROOT CO.,**  
 10 Vine St., Philadelphia, Penn.

Now is the time to order  
**Shipping - cases, Winter Cases, Chaff Division-boards, etc., etc.**

Order from catalog; prices are same as from factory.

## Shipping-cases.

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA.** Immense stock. All orders for cases or other goods shipped by return freight. Address

**JOS. NYSEWANDER, Des Moines, Iowa.**

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would heed a new one this summer I write for a circular. I do not think the 4-inch Smoke Engine too large.  
 January 27, 1897. Truly, W. H. EAGERTY, Cuba, Kansas.

**T. F. BINGHAM, Farwell, Michigan.**

## Weekly Bee Journal One Year for 25c.

To every *new* subscriber who sends us \$1.50 before Jan. 1, 1898, we will mail a copy of Prof. Cook's 460-page cloth-bound book, "**BEE-KEEPERS' GUIDE**" (price \$1.25), and the **Weekly American Bee Journal** for one year. That makes the **Journal** only 25 cents—a trifle less than half a cent per number. Or, if any one now getting the **Bee Journal**, and whose subscription is paid to Jan. 1, 1898, will send us \$1.50, with a new name, we will mail the above book to the sender, and the **Bee Journal** for a year to the new name and address. We need hardly tell you what the **American Bee Journal** is; but if you are not acquainted with it, write us for a *free sample copy*.

**GEO. W. YORK & CO.,** - **118 Michigan St., Chicago, Ill.**

# GLEANINGS

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

## BEE CULTURE

ILLUSTRATED  
SEMI-MONTHLY  
Published by THE A. F. ROOT CO.  
\$1.00 PER YEAR MEDINA, OHIO.

VOL. XXV.

NOV. 1, 1897.

NO. 21.

### STRAY STRAWS

FROM DR. C. C. MILLER.

THIS YEAR 17,728  $\frac{1}{8}$  sections averaged 14.41 oz. each, against an average last year of 15.088 oz. [Can you give any reason, doctor, why there should be a whole half-ounce difference between this and last year?—Ed.]

DOOLITTLE SAYS, page 737, that with drawn foundation for bottom starters only two rows of cells are needed. I wish he'd tell us what he has tried "along this line." I've found more trouble about having very narrow starters of foundation gnawed down, and feared it would be the same way with drawn foundation.

HONEY-BOARDS, that so many of us have been replacing with thick top-bars, have a good word in *A. B. J.* from F. L. Thompson. He thinks sections are whiter over the honey-boards. With very black brood-combs a greater distance helps about keeping sections white; but does the gain in whiteness pay for the extra trouble, time, and expense?

THE EDITOR of *Review* expects to be at the Northwestern convention at Chicago, Nov. 10, 11. How about the editor of *GLEANINGS*? Don't think of my ever speaking to you again if you don't come! [If I can possibly go I will. But some unforeseen circumstance will very possibly prevent my coming at just the date on which the convention is held.—Ed.]

SOMNAMBULIST, who dreams out such wide-awake ideas in *Progressive Bee-keeper*, wants to know if I didn't learn the value of sleep at Buffalo, and says: "The 'stay-at-homes' have at least a crumb of comfort in the knowledge that we didn't have to sleep on a cot, with old shawls for a mattress." Look here, Sommy, those cots had first-class woven-wire mattresses, and I slept just as well as if on a gilded couch until Leland, hopeful scion of the house of Root, came hammering me to wake me up.

PROF. COOK believes in bee-keeping for others than specialists, and says I accuse him of changing his mind in that regard. I kind o' think he'll change his mind again if he'll look up what I said. The only place I find where

I said any thing about it is on p. 585, where I said, "Prof. Cook favors a return to the old plan of having a few bees on every farm, rather than large apiaries in the hands of specialists." That doesn't mean that you've changed your mind, professor, but that you want others to change their practice.

ELIAS FOX is entirely right, page 739, that locality does not rigidly and entirely control taste. While the general rule holds that people in general prefer the honey of their own locality, plenty of exceptions are to be found. Buckwheat honey is hardly known here, and yet some of my friends much prefer it to the best white clover. It's not a matter of cultivation; they seem to be born with a buckwheat taste. He is also right that one colony will propolize three times as much as another in the same apiary.

T. GREINER, the well-known agricultural writer, although not a bee-keeper, was present at the Buffalo convention, unfortunately at a session when there was what he calls a disgraceful squabble, and in *Farm and Fiveside* he advises as an outsider that Mr. Benton, who is a meritorious but impulsive bee-man, should gracefully make amends for offensive personal remarks, and abstain from referring to the services he might render, or refuse to render, in his official capacity to the society, and then be reinstated to full membership. Not bad advice.

THE VARIATION in the weight of finished sections this year was very great. The lightest case of 12 sections was  $8\frac{1}{2}$  lbs., and the heaviest case 12 $\frac{3}{4}$  lbs. Of course, the lightest section of the lightest case and the heaviest section of the heaviest case were still farther apart. It hardly seems right to sell such sections by the piece. [Say, doctor, you want me to knock that chip (honey by the piece) off your shoulder. I just won't do it, but next time I go out among bee-keepers I will stick you on the rear end of my bicycle, if you don't get too fat, and let you see that selling by the piece, in some localities at least, is the simplest and easiest way, and in accordance with the Golden Rule.—Ed.]

I CAN'T TELL whether you're in fun or earnest, Mr. Editor, p. 730, so I don't know whether to get mad or not when you say you'll make a glossometer to measure the tongues of

Doolittle's bees *after* he stretches 'em. Why, bless you, he must have the glossometer to select the ones to breed from so as to stretch the tongues of the next generation. Say, what can you furnish a good glossometer for? [I am sorry, but I really can not tell whether I was in fun or in earnest on page 730. About that glossometer—well, I do not know about what it would cost—don't care much; but we have one in the garret somewhere in a cubby-hole, or on a shelf, that Doolittle can have if he will simply ask for it. It was made by J. H. Martin, and is illustrated on page 220 of GLEANINGS for 1882.—ED.]

W. P. FAYLOR lets his customers sample comb honey and extracted side by side, calling attention to the greater thickness of the extracted article, and, as a result, sells ten pounds of extracted to one of comb. But he doesn't give the relative prices.—*Am. Bee J'l.* [Mr. Faylor is working on the right plan. The majority of bee-keepers, I think, would prefer, for their own table, extracted honey, provided it is properly ripened; and I believe the majority of consumers, if they could be sure of the purity of the honey, would prefer the extracted. While a great many, it is true, prefer comb honey, the element of cheapness in favor of the extracted would go a long way to show that Faylor's policy is a good one.—ED.]

THIS YEAR, from 239 colonies, spring count, I got 17,150 lbs. honey, all comb but 300 lbs. That is the biggest yield I ever got, but not the biggest yield per colony. [Doctor, that is grand; and, if I mistake not, the labor of securing this crop was all performed by yourself and women-folks. It would be interesting to know approximately how many days it took you and your family to secure that crop. What I mean is, how many days it took you, counting the time of preparing sections, hauling bees, putting on the sections, putting into and taking out of the cellar—in fact, every thing connected with the bee-work. With another year or two like this you will have more than made up for the poor seasons you have had, and perhaps you have already. There is nothing like sticking and hanging to a business, even if it does not pay very well some years.—ED.]

SOMETHING LIKE A BOOM seems to be started in *American Bee Journal* for figwort, or Simpson honey-plant. That means some people are going to be disappointed. Geo. W. Williams says an acre of figwort is worth ten of sweet clover, and he considers figwort the only plant worth cultivating for honey alone. While that may be true for *him*, it is also true that, of the many who have tried it, perhaps no one else would coincide with him. [Our own experience, so far as I can remember, would lead me to believe that G. W. Williams' estimate of figwort as against sweet clover would not be far from right. I feel quite sure that a plant of figwort, taking about the same amount of ground as an equally vigorous plant of sweet clover, would yield ten times as much honey. Many and many a time I have watched the bees on our figworts. I have

seen single bees take from a single cup or floweret of this plant about all the nectar it could carry at one load. While the drop is not quite so big as one from the spider-plant, there are many more of them.—ED.]

"BEES GATHER WAX in dull seasons," says the editor, p. 738. I think I have had some evidence that not a particle of such wax is ever used in comb-building, but only as a substitute for or in combination with propolis. [I think I have some evidence that a good many particles of such wax at such seasons of the year are used in comb-building. For instance, let me refer you to Figs. 5 and 6, p. 640, Sept. 1. And don't you believe that the bees almost invariably build combs heavier—that is, with thicker walls and thicker bases—in dull seasons, or when the honey-flow is very moderate, than they do at other times when honey is coming in at a good rate? But I suspect you are right, nevertheless—in fact, I know you are—in thinking that bees use a good deal of wax that they gather from old combs left exposed, as a sort of filler to go along with propolis.—ED.]

EDITOR YORK is a great believer in sweet clover. He pummels Prof. Pammel for saying it's a weed. Better arbitrate the matter. A valuable plant in one place may be a weed in another. One of the worst weeds I ever had to fight in a rose-bed was white clover. [I can not exactly see how something could be a bad weed in one place and a valuable plant in another—at least, not how sweet clover could be a noxious weed in *any* locality. Experience everywhere, so far as I know, shows it is very easily kept down, and that it never bothers on cultivated land. The mere fact that it grows profusely along all roadsides, where it is rarely if ever molested, gives a careless observer the impression that it would be a serious enemy to the farmer if it got started on his land. But every good thing has to have its opposers until it can have time to win its way and show that it is not as bad as its enemies think it is.—ED.]

PARAFFINE PAPER over sections, F. L. Thompson says in *A. B. J.*, is too fussy; and after the early part of the season the bees daub propolis between sections and paper. My own experience says that entirely too much has been claimed for paraffine. My bees deliberately plaster glue right on the paraffine. [It was I who, about a year ago, spoke favorably of paraffine paper; but at the time, I stated that Mr. Danzenbaker and Hon. Geo. E. Hilton had obtained good results with it, but added that we had not tried it. I am sorry to have to acknowledge, however, that our own experience on a limited scale has not been entirely favorable—rather otherwise if any thing. Mr. Danzenbaker, however, has especially emphasized the fact that bees will invariably gnaw through the paraffine paper unless it is cushioned thickly on top—that is, between the paraffine paper and the cover—with folds of newspaper, quilts, or any thing that will press the paraffine paper tightly against the sections. But we did this, and the bees gnawed into it—or, rather, we used a

super that Mr. Danzenbaker had prepared as being just right, and the result was as stated. I should like to know whether the doctor, or friend Thompson either, cushioned the paraffine paper down. In the mean time perhaps friend Danzenbaker would like to say a word.—Ed.]

### PEDDLING MADE EASY.

A Few Capital Suggestions; Giving Away Samples and Taking Orders Afterward; the Value of the Honey-Leaflets.

BY DAN WHITE.

I told you in my last article that I had about 7000 lbs. of extracted honey, and expected to sell every pound of it near home, and promised to report later on how I got along, so I will tell you about my experience in new territory.

You see I must reach out further than ever before, so I decided to try a place twenty miles away—a place of about five thousand people; so one morning I packed my grip and took two 12-pound cans of honey and started out. About all I had in my grip was a good supply of those leaflets published by The A. I. Root Co.; then 50 postal cards addressed to myself.

I got into the town just before dinner time; and after eating a good meal at a boarding-house I filled my pockets with leaflets and took one honey-can and commenced business. I started down a street and did not miss calling at every house. After ringing the bell, or rapping, a lady would open the door and look at me with more or less suspicion. I would say, "I made the call to ask you if your family were fond of honey."

"They generally answered yes, but believed they would not buy any.

"Well," I would answer, "but I am not selling honey to-day. I am giving it away, and should be glad to give you some in a sauce-dish."

Some would look astonished, others would smile, and say, "That's funny," but in every instance I was invited in. I would pour out the honey, then hand out a leaflet, telling them to read every word of it. "You will find it very interesting; it will tell you all about honey—how and why we extract it, etc. Then here is a postal addressed to me; and should you decide to want a 12-pound can, put your name, street, and number, on the card; drop it in the office; and when I deliver in about ten days you will get a can of honey."

Well there were enough cards put in the mail within five days to take thirty cans of honey. I promptly made the delivery on time, taking along twenty extra cans that sold about as fast as I could hand them out; and since then I have received orders for 50 more cans from the same town. I tell you, it has got all over town that a honey-man had been there selling *real* honey, 12 pounds for one dollar. I am certain this one place will take over 2000 pounds, all in one-gallon cans.

Now, then, 18 pounds of honey given away from house to house; 50 postal cards, 200 leaflets left at houses and handed to people on the street, and one day walking over a very small portion of the town, has found a place for at least 2000 pounds of honey. Then think what I can do next season should I secure a good crop. All I shall have to do is to take a big load and go up there and hand it out. By the way, the honey sold there was thrown out of clean white combs, over every inch of whose surface the uncapping-knife had to go. It weighed strong 12 pounds to the gallon—just as good as the best comb honey, *only* it was out of the combs. Of course I can go back just as often as I choose; yes, and the people will all be glad to see me.

We read about the trouble in grading comb honey, and just how to get it in the market to the best advantage; but I want to ask, what would happen with comb-honey producers if the bees could only be influenced to fill the section combs one day and cap over ready for market the next day? I imagine there are some who would favor this very thing. Yes, sir; some would advertise a strain of bees that could be controlled in that direction easier than any other strain. Others would say, "Hold on! my bees must go on in the good old way, and not cap over any honey until it is ripe and wholesome to eat." We will call the latter class honest men who can build up an honest trade for their honey, and then hold it if the former class would just keep away. Now, sir, I shall call the *former* class dishonest, not only to their customers, but dishonest to themselves *especially*, if they expect to continue in the business. Then they would be dishonest because they would do a great injury to the honey market in general, and this is the very worst thing of it all. Don't forget that *very few* people get tired of good first-class honey; and, above all, remember that almost any one will tire of poor, thin, unripe honey.

One thing we must always expect; and that is, some of these fellows who have only a few colonies of bees will annoy us by extracting poor honey, and finding some one to buy it, because they call it honey, and often find customers because they make a price below any thing heard of. This class, of course, don't care, as they care nothing for a reputation. Some seasons they have a little to dispose of, and other seasons they make a failure. Thank fortune for their failures! But what can we say to bee-keepers who handle large apiaries, to convince *them* they are doing wrong? I personally know several who are scattering this unripe honey over the country. This makes me believe there are just lots of these fellows, because my acquaintance does not reach out very far over this broad land.

I am saying more than I want to about this; but I am in earnest, and wish I could influence some or all to see as I do, and then see how easy it will be to dispose of our honey.

Only last season a man called on one of my customers who annually buys from 50 to 75 pounds of me. Being out of honey he was influenced to take 50 pounds of *his* honey.

One reason he bought of him was because the price was lower than he had ever had it offered. You see, this was two or three weeks earlier than I could get any *good* honey for my customers. I found this out when I did call, and told him he had made a mistake. Now, here is the secret of all this. When I called on this family this season with some *good* honey they had plenty left over from last season's supply. What must I now do? Well, I will tell you. Start all over new; call for a dish, and give them some to renew that taste for honey. It worked just like a charm, for it was only a day or so when I got an order for 20 pounds; and later on, 40 pounds.

I could enumerate several places where this energetic hustling bee-keeper caused this same trouble. Now, is it surprising that we hear so much about poor honey markets, especially extracted honey? I don't want any one to think I am worrying about the sale of my own honey, because they will be very much

read what he has to say, the more I believe he is chock full of good hard common sense.

Peddling seems to be very distasteful to many; yet the most disagreeable feature of it is removed by the method proposed. To knock at the front door and try to *force* a sale is something that nine-tenths of us will not do; but to tell the lady of the house that you are not selling anything to day, and that you would like to *give* her a sample of nice honey—why, it seems to me that would be easy. Then the idea of letting the honey-leaflet and the postal card do the talking, and take the order afterward—well, it is the best idea that has yet been proposed.

I hope every reader will take pains to read this article. Try the scheme, and then report. You may not all be as successful as was our friend Dan, with his honest-looking face and general appearance of one who earns his bread and butter and honey by the sweat of his brow. I tell you, it is worth a good

THE FALLEN BEE-TREE; THE CHILDREN THAT ATE THE HONEY.—SEE EDITORIALS.

mistaken. My aim is to see if I can't fix it so these fellows who want to sell and market their honey can feel as good about it as I do.

I have said enough for one time, and will close after telling one thing more that I candidly believe to be true. Now listen. If the people in Ohio were properly supplied, or eating what honey they would eat if it were put before them in the right shape, the supply would not equal the demand, even if every State joining should depend on Ohio for a market. Use your customers right. Look up your own territory right; peddle no better than I do, and you will believe as I do.

New London, O.

[I have spoken highly of our friend Dan White before; but the more I see of him, and

deal to have an honest heart inside; for in a short time it will blazon itself in big letters all over the man. I am going to ask Dan to send us a photo of himself.—ED.]

#### DEVELOPING THE HOME MARKET.

Trading Honey for Ducks, Pigs, and Pnps; an Interesting Experience.

BY GEO. L. VINAL.

In all the literature on bees and honey, we are urged to develop the home market. Acting on the advice, after I had traveled over my regular route this fall I went into an entirely new locality. After enjoying the scenery

and the sunlight for about a five-mile drive I called at a farmhouse and inquired of the good lady if she would like some honey.

"Well, yes. I should like some, but I have no money."

Seeing some ducks, I offered to trade honey for ducks; and for a pair I gave four pint jars of honey.

Calling at another house, I sold \$2.00 worth for cash; and while I was talking with the man one of the ducks gave a quack, which lead to an inquiry as to what I had. I told him I had traded honey for ducks.

"Well, now, look here; can't I trade you some hens for some honey?"

I traded for half a dozen, and made the children, I hope, happy (I was). In this way I passed the day, and on my drive home I was trying to figure out my profits.

I had disposed of two gross of pint jars, and 120 pounds of comb honey. For the pint jars I received 25 cents; also 25 cents each for the sections of comb. I had had a royal day's sport; and as I listened to the quack of the ducks and geese, the cackle of the hens, and squeal of the pigs, and looked at the large box of eggs that I had in the wagon, I thought I would have to send for some of Dr. Mason's egg-preservative.

After getting home I took account of stock. I had \$54.40 cash, 108 dozen eggs, 8 ducks, 1 goose, 2 pigs, 24 hens, and 1 bullpup. (The pup is for sale.)

Charlton City, Mass.

### THE TALL SECTION.

Who First Brought It Out? Patents.

BY F. G. BASS.

*Mr. E. R. Root:*—Why do you allow readers of GLEANINGS to be misinformed by calling a copy of a section used by Capt. J. E. Hetherington for the past twenty years the "Danzy" section? I suppose it is because you are not posted. Please allow me to inform you that the so-called "Danzy" section,  $3\frac{3}{4} \times 5 \times 1\frac{1}{2}$ , was copied from J. E. Hetherington's section in this State five years ago. I see the "Danzy section" is now changed to  $4 \times 5 \times 1\frac{1}{2}$ . Why not change again to  $4\frac{1}{4} \times 5\frac{1}{4} \times 1\frac{1}{8}$ , so those who wish to deceive the eye can do so by simply adding one inch to the top of old supers? If this does not satisfy you as to who is the originator of the tall section, I will go into particulars, as I am personally acquainted with the parties and facts in the case.

I notice great change in the management of GLEANINGS. Instead of fighting against patents on bee-keepers' supplies, it is controlling patents on foundation and bee-hives. I do not see why we should not patent them as well as other agricultural implements.

Front Royal, Va., Oct. 18.

[Why, my friend, you are not posted on what has been printed in GLEANINGS. Mr. Danzenbaker does not claim that he introduced the deep section. In fact, I think he has stated more than once that Capt. J. E. Hether-

ington was using sections  $3\frac{3}{4} \times 5 \times 1\frac{1}{2}$ ; and I know he has said that, after he had been to Capt. Hetherington's, and seen his beautiful honey, he became convinced that the deep sections were the ones he would use.

Why do we call the section the Danzy? For the reason that it has a peculiar opening or bee-way. There is no lee-space on one side, and a bee-way on the other, and those bee-ways are decidedly different from those Capt. Hetherington uses. The latter would probably not care to father such a form of section, and we have therefore called the section the Danzy. We are very well aware that Capt. Hetherington was one of the first to use deep sections, and we are sure we have no desire to deprive that distinguished bee-keeper, whose good will we value much, of his rightful credit.

Yes, indeed, we believe that *worthy* inventions, even in apiculture, should be protected by a patent. The "boys," of whom I am one, have never experienced a change of mind in regard to the subject of patents. We stand to-day just where we always have stood; and A. I. R., while somewhat of the same opinion as before, has no desire to interfere with the changed policy regarding patents.

*Later.*—Since writing the above, Mr. Weed has called my attention to the fact that the "deep section is older than the hills." We have run across an old volume of Kidder, published in 1868, where the deep section is illustrated and described on p. 174. The remarkable part of these sections is that they had no bee-ways in them. They are simply boxes without top or bottom, deeper one way than another, with plain edges. A sort of cleated separator was used to regulate the bee-spaces. Even Kidder himself does not claim that this section was original with him.—ED.]

### POISONOUS HONEY-PLANTS.

Scotch Heath.

BY MRS. L. E. R. LAMBRIGGER.

Replying to Dr. Miller's Stray Straw in Oct. 1st GLEANINGS, I would say there is probably no mistake about the existence of Scottish heather in New Jersey. The late Peter Henderson, himself a Scotchman, says: "*Calluna vulgaris*, the only species, is the well-known heather of Scotland, popularly known as ling, or common heath; a low-growing, much-branched little shrub, with very pretty rose-colored, purple, or white fragrant flowers produced in crowded axillary clusters, forming one-sided (mostly) spikes or racemes. This beautiful little plant has become naturalized in a few localities in America. It is reported at Tewksbury, Mass., and at Cape Elizabeth, Maine. It is also found sparingly in Nova Scotia and Newfoundland."

NATURAL ORDER, ERICACEÆ.

Turning now to Gray's Manual, page 318, I find the following:

"*Calluna vulgaris*. Low grounds, Mass., at Tewksbury, and W. Andover; Maine, at

Cape Elizabeth; also N. Scotia, C. Breton, Newfoundland, etc.; probably only introduced."

Further down same page occurs this:

"Two European heaths, *Erica cinerea*, and *E. tetralix*, have been found in small patches on Nantucket Island."

Turning again, this time to my encyclopedia, I quote:

"*Calluna vulgaris*, sometimes called the ling, is the common heath, or heather, and

two, *E. cinerea* and *E. tetralix*, are widely diffused and abundant; the others are more local.

To summarize, and add a few words of explanation that the reader may not be confused regarding terms:

*Calluna vulgaris* and *Erica cinerea* are one and the same plant; viz., Scottish heather. I myself did a good deal of searching and comparing of botanical terms and definitions before I found this out. When two high authorities seem to conflict, or are most provokingly silent and obscure where they should be the very reverse, it is often difficult to get at the truth. Our only recourse is books—more books—many books—reference works; and the average home is not overstocked with these.

The Latin word *cinerea* means ashy gray, or ash-colored, and not fine-leaved, as one authority gives it. The heather belongs to the heath family; but all heaths are not heather, and this brings us right to the point under discussion; viz., poisonous honey. I do not claim to *know* whether any living plant secretes poisonous nectar. I wish I did know, as in that case I would soon end the discussion. My aim is to try to help find out. To this end, allow me to again quote Peter Henderson, the father of horticulture in America. Under the head of "Poisonous Plants" he says:

"Of the 100,000 known flowering plants, it is stated that 10,000 may be considered deleterious, all being more or less energetic in their action; and of these, probably fifty are deadly.

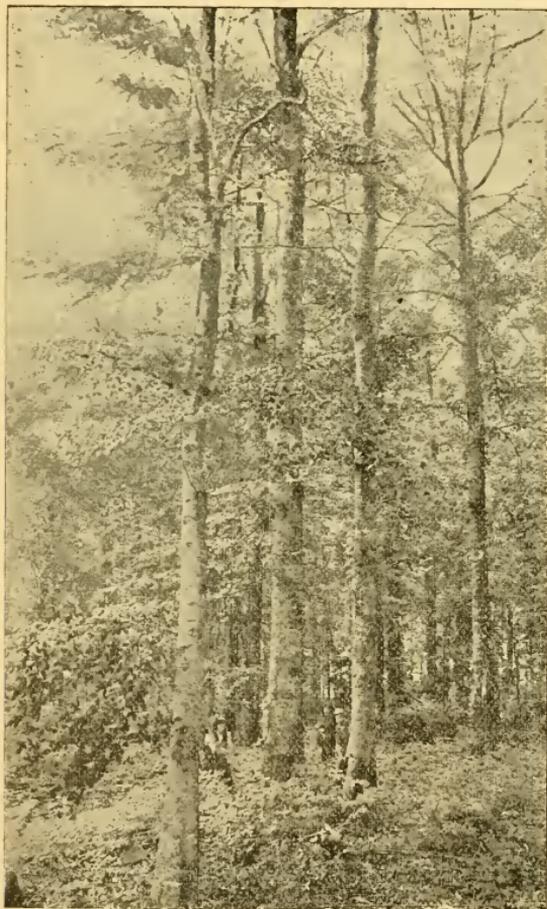

It is a singular but generally understood fact, that all plants having green flowers are poisonous, either in their leaves, stems, seeds, or roots."

He then adds:

"*These dangerous qualities are generally mentioned in this work*"—meaning his "Handbook of Plants." Italics mine.

Now, friends, I have studied the subject very carefully. *Azalea pontica* is the heath from which the honey was obtained that is supposed to have poisoned Xenophon's soldiers; but Mr. Henderson makes no comment on the plant, further than to state that it is a native of Turkey. In like manner he has only good words to say of the mountain laurel, *Kalmia latifolia*; but in treating of its near relative, *Kalmia angustifolia*, he tells us that it is deadly to sheep. On the other hand, my encyclopedia gives the following:

"The leaves of *Kalmia latifolia*, the laurel

OHIO WOODS—CUTTING DOWN A BEE-TREE.—SEE EDITORIALS.

the most abundant species of the family in Britain. It is the plant whose flowers render the slopes of most Scottish hills pink in autumn, and the one so abundant in Epping Forest. Ornamental varieties are sometimes grown in gardens. The plant is astringent, and is employed by both fullers and dyers, and the flowers are very attractive to bees."

The genus *Erica* comprises about 400 known species, of which five are British. The first

ivy, spoonwood, or calico-bush, are poisonous to many animals; and the flesh of pheasants which have fed on it is said to be deleterious to man. A honey-like juice exuding from the flowers brings on phrenetic excitement."

Can Prof. Cook enlighten us as to the probable truth of the last statement? For myself, I offer no settled opinion on the subject; however, I am decidedly in favor of having the matter ventilated to its fullest. In a few days I shall be in receipt of a new and up-to-date reference library. This subject will be the first looked into; and if I find any additional light, or confirmation of what we have, I promise to report.

Niobrara, Neb.

#### A FEW MORE FACTS CONCERNING THE RIETSCHÉ PRESS.

BY F. L. THOMPSON.

*Mr. Root:*—I will assume that both of us want to get at the exact truth concerning the Rietsche press, and so confide to your tender mercies a few more facts. My two chief points are, first, that we do not know enough of the Rietsche machine; second, that many can not afford to buy foundation, and, if possible, something ought to be done for that class.

In the August number of *La Revue Internationale* is an article on the Rietsche press from the manufacturers' point of view, by Alf. de Trey. He says the fact that Rietsche foundation is more rapidly worked by the bees than factory foundation is simply due to its greater thickness, and that he knows this by experience. He also contends that this greater thickness destroys the advantage of cheapness, making a difference in value of wax amounting to 1 franc for every 9 Dadant frames; and that the brittleness is so great, since Rietsche foundation can not be handled readily below a temperature of 19° (apparently centigrade = 61½ F.), that a number of people he knows have been completely discouraged by that fact. Ulrich Gubler comments on the article by asking whether exposing the sheets to the sun before using is more trouble than to write to the manufacturer, wait some time for the merchandise, and unpack it when it comes; and that thickness is far from being a fault; for if a swarm finds an extra pound of wax in its sheets, it does not have to produce it; hence, six pounds of honey is saved, as well as the time for gathering as much more. (This last argument seems to me rather singular. Under certain circumstances, and generally, I believe, bees build combs from foundation without making all possible use of the wax therein contained, or anywhere near it. Still, there may be something in it. Did not the report of the Ontario Station give an account of an experiment with black foundation, in which the completed cells showed a regular gradation of tint from the septum to the outer edges of the cells?)

From the above one might conclude that both sides agree Rietsche foundation is always thicker than factory foundation; but this con-

clusion would be at least dubious, for neither of them says any thing about wire, and we know that Rietsche foundation abroad is used without wire, whatever may be the reason; hence the comparison may be between unwired Rietsche foundation and wired factory foundation, which would hardly be fair.

I also ran across an old catalog of German bee-supplies, which I did not know I had. According to this, when a sheet measures 25 x 20 centimeters, 20 is the depth. I had supposed these were full-depth dimensions, which would have made the longer dimension vertical. However, the fact that it was intended to be used without wire is sufficient to account for the weight of the sample you received. The smallest press, 22 x 17 centimeters, costs, with packing, 10 marks, or \$2.38; the largest, 45 x 30, \$8.15. I estimate the L. size would be about \$5.36. There are 10 sizes in all. A simple device does away with any necessity for trimming the sheets. The chief instructions are as follows:

"Apply to the plates with a brush a mixture of one part honey, two parts water, and three parts pure alcohol. Pour wax on the under plate, and shut quickly. Shake the surplus back into the wax vessel. Cool in water, if necessary. Open and remove the sheet. The time consumed for all this is about one minute. The amount worked by one man per hour is from one to three kilos, according to the size of the press; consequently, a press soon pays for itself. The sheets are thin or thick according to the temperature of the wax and degree of cooling, so that thin or thick sheets may be produced at pleasure. After some practice it will be easy to make a square meter of foundation with moderately high cells out of a kilo of wax, or 1¼ square meters with shallow cells. A surface of four-fifths to one square meter is just enough to be completely worked up out of the wax given."

Rietsche's advertisements now say 150 sheets an hour are made, with no brushing nor expense for lubricants; and, as you will recollect, the thinnest made is 1.35 square meters to the kilo, instead of 1.25, as above. The chief point to be noted in the foregoing is the manner of producing thin or thick sheets. Perhaps this has a bearing on your experience with the machine.

It just struck me that the largest size of press kept in stock (any size may be ordered) being 45x30 cm., hence a trifle longer one way than the L. size, which is 20x43 centimeters, there would seem to be no practical obstacles in the way of working a *double L.* size, 40x43, and cutting the sheets in two afterward. Then what would become of all your calculations? Whoopee!

But, really, in my case at least, I would lay very little stress one way or the other on the number worked per hour, within reasonable limits. It is that 41—25 = 16 cents per *pound* used that I want to get out of paying.

Montrose, Colo., Sept. 20.

[Perhaps our readers are already getting tired of this discussion; but we hope to have the truth come out, let it strike where it may.

Some of the things that friend Thompson has given favor my side, and some favor his own. So far as these last relate I will let them stand on their own merits. I simply desire to call attention to the fact that there seems to be a disagreement among those interested in the sale of the Rietsche press. The manufacturers themselves give rather indefinite figures as to how much per hour their press will make. For instance, in the article above they say that 150 sheets per hour are made; but there is no reference as to the *size* of the sheets. It is hardly fair to assume that a large sheet could be made as rapidly as a small one, as intimated in friend Thompson's next to the last paragraph; but I have found something definite myself from a dealer who sells Rietsche foundation-presses in Australia. His advertisement appears in the *Australian Bee Bul-*

three or four pounds per hour we can hardly figure on more than 20 or 25 lbs. as a day's work. Then the brittleness of the article after it was made would be somewhat against it.

Mr. Thompson is laboring under the disadvantage of having never used one of the Rietsche presses. If he will pay the cost of a late machine we will pay the cost of transportation; and I would suggest that further argument be deferred until such a time as he shall have actually tested the machine so that he will not have to depend upon what some one else says. My arguments all along have been based on our own experience with a Rietsche press. When we bought it our intention was to make some arrangement to put it on the market if it should prove to be a good thing.

If it shall yet turn out to be a great help to a certain class who can not afford to pay high

NIVER AND HIMSELF.—SEE EDITORIALS.

*letin.* In referring to the Rietsche press he says:

"Foundation may be made at a very slight cost of labor; capacity, 3 to 4 lbs. per hour."

This cuts the estimates down that friend T. has been making, just about a half; and I am more inclined to believe that this is actually the capacity of the machine, because these figures are just about what we were able to secure with the press we have. This advertisement appears in the August 24th issue, and doubtless referred to late machines.

If three or four pounds of foundation per hour is all that can be made from an L. sized Rietsche press, I can not by any combination of figures, allowing the operator \$2.00 a day for his time, see how any great saving could be effected over factory-made foundation. At

freight rates, let alone the cost of ordinary foundation, we as manufacturers of supplies would be very shortsighted if we did not supply such customers with these hand machines. I am open to conviction; and I believe friend Thompson is also, and that he will test the machine fairly, because his article above shows a spirit of fairness and a desire to get at the truth.—ED.]

#### VALUE OF CLEATED SEPARATORS.

Comb Honey "as Straight and Smooth on its Surface as a Planed Block of Wood."

BY JULIUS TOMLINSON.

I have just been reading your Oct. 15th issue, and was particularly interested in the

new separator you wrote so much about on page 741. According to my present light I think them a good thing, for I have tried them this season. I got my idea from R. C. Aikin (in GLEANINGS for April 15, '97, page 275), but I rejected his idea of supporting sections by little nails driven into the separators. Instead I floored my section-case with thin strips, scored out on the edges, for bee-spaces. The separators are  $\frac{1}{8}$  in. thick, and the strips across the same are  $\frac{1}{8}$  also, on each side. This keeps the sections just  $\frac{3}{8}$  in. apart. The bottom and top of sections are  $1\frac{1}{4}$  in. wide; uprights of sections  $1\frac{1}{2}$  in. wide, which gives a bee-space of  $\frac{1}{4}$  inch between top and bottom of sections, and the honey in the section is just  $1\frac{1}{4}$  in. thick, and exactly even with top and bottom pieces, and as straight and smooth on its surface as a planed block of wood. When crated, the combs are  $\frac{1}{4}$  in. apart, and need no separators. I never had honey in nicer shape than in those sections. The floor in the case prevents the bees from coming in contact with the sections, and I think that, in another season, I shall cover the sections on the top also with thin bottom floor strips.

Instead of glue for fastening on strips I use small clinch-nails—such as are used for making peach-baskets—and with a suitable form it can be done quite rapidly by any boy or girl. Of course, it is some work to fix up section-cases this way, but not more than wide frames, and it is no trouble at all to take the sections from the cases. I have a way of my own for pressing the sections together in the cases, both endwise and sidewise. My section-case is a plain box halved together at the corners, and nailed both ways.

Allegan, Mich., Oct. 23.

[I had forgotten the fact that so good an authority as R. C. Aikin uses and recommends cleated separators when I wrote the article in our previous issue, page 741. As time goes on, I have no doubt we shall find that a larger number of bee-keepers than we had any idea of saw the advantage of cleated separators and made use of them.

I notice that you emphasize the fact that this style of separator gives you comb honey "as straight and smooth on its surface as a planed block of wood." Why, it seems to me that any one who would think of using the old style of separator in preference to the new one would be simply shutting his eyes and throwing away his dollars—none so blind as they who will not see. I do not think or guess or theorize. The proof of the pudding is in the eating. The honey that has been produced by cleated separators speaks for itself. The sections are not only better filled out, but plumper, and, as I stated in our last issue, would grade at least one notch higher in the open market.

Well, it seems here is another man who also caught on to the advantage of this style of section, and we will let him speak for himself; and in the mean time we should like to hear from others who have been using the same or a similar device. Let us hear all the bad things about them as well as the good. —Ed.]

#### HOW AND WHY THE NO-BEE-SPACE SECTION OF HONEY BRINGS A HIGHER PRICE.

*Mr. Root:*—Referring to editorial column, page 744, you speak of non-bee-space sections. I want to say that I heartily agree with you in all you say about the pleasing effect they *present* when looking at the face of the section. No one looks at section honey edgewise when buying, unless to see whether it is cleaned of propolis; consequently the section that is filled out to the edge, and evenly capped, no outside cells uncapped, which is so common with the bee-spaced section, is the kind of section honey that will sell ninety-nine times out of a hundred first—*every* time when sold by the section, even if the bee-spaced section did weigh a little heavier.

During the honey-flow this season my circumstances were of such a nature that I could not purchase such goods as were needed (caused by misfortunes in the past two years, over which I had no control); consequently, in order to procure the honey my bees would gather I was forced to plan some arrangement for surplus. After I had used all sections until others could be had, so I had a lot of brood-frames in the flat, they were put together and spaced with horizontal and perpendicular thin strips. Starters were put in and given to the bees, and were spaced to about  $\frac{3}{8}$  inch; and, oh my! that was the loveliest sight of honey, when taken off, I ever saw. I do not believe there were a dozen uncapped cells in the entire lot. Every section was built out as even as a planed board; in fact, it was a solid block of honey.

A few days after this honey was taken off, a gentleman called for some honey; and while I was about to wrap up seven of my nicest filled sections, the gentleman spied those large frames, and was so fascinated by their appearance he exclaimed, "Say, Mr. G., is this honey for sale?"

"Yes, sir."

"How much have you like this?" pointing to a frame hanging up in my honey-room, "and the price?"

I said, "I think about 40 lbs., and 15 cts. per pound."

"Well, you needn't tie up those boxes. I'll take the 40 lbs."

Now, why did this gentleman buy that honey in preference to a dollar's worth of as nice bee-space-section honey as it's possible to produce by any apiarist? It was all white-clover honey. It was the pleasing appearance it presented by being built out even with the edge of the frame, and no uncapped cells, which always make a section look as if it contains more beeswax than honey.

Here is another observation proof in my method of manipulating bees (swarms), caging the queen, placing her in sapper, and hiving the swarm back, as stated in former articles. In preparing the cages I take a number of the one-piece sections, place them between two boards, and place them in the bench-vice; then with the plane I dress off the projecting edges. They are then put together, then each side is covered with wire cloth. Not having

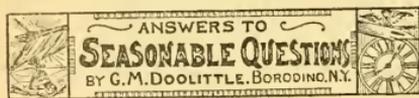

enough sections to fill out a super, it occurred to me that I could fill out with the so prepared queen-cages, and I took off the wire cloth, and inserted eight of those dressed sections, slipping little strips between rows to give a bee-space, which answered the same as the slatted separator, never thinking what the result would be, more than to save the honey the bees would gather; but when I took that crate off I was so pleased with those eight sections that I said to myself, "Next year I'll fix 'em."

Those eight sections were all filled out even with the edge of the section, or so nearly so that two could be placed together and the two face surfaces would nearly touch together; and as I keep nice glassed cases of honey in our stores, those sections were placed in those cases with the other bee-spaced sections; but the eight non-bee-spaced were the first sold, and because they looked as though they contained more honey for 15 cts. than the others, and I am not so sure but they did; however, I did not think at the time to test them by weight.

So, Mr. Editor, should I live to manipulate bees through the season of 1898 I shall test this matter pretty thoroughly; also the drawn-foundation comb, of which we have read so much.

J. A. GOLDEN.

Reinersville, O., Oct. 23.

#### WINTER-PASSAGES IN COMBS NOT NECESSARY.

*Question.*—I see in one of my papers that one writer claims that old age can be set down as the reason for bees dying in winter without apparent cause, and asserts that the cause of the loss of many colonies lies in the fact that the same was composed mostly of old bees at the approach of cold weather. This may be the cause of some of the loss; but I think the loss is more often caused (where bees are wintered on their summer stands in the open air) from chill, or the impression from cold of those occupying outer ranges of comb, during sudden changes from warm to very cold weather. Especially is the loss very considerable from this source where the comb-passages are deficient, as they generally are where large frames are used; as in such case the detached clusters are unable to readily join the main cluster, and are not in sufficient numbers to maintain the requisite degree of heat, and are thus lost. Considering these facts, do you not think it well to make winter-passages through the combs, near the center, for the bees to pass through?

*Answer.*—The above brings up a subject which was discussed at length several years ago, when there was a "craze," as it were, for "winter-passageways" through the combs. The argument then brought forth was, that on the first cold spell the cluster of bees is

obliged to contract in order to maintain the necessary degree of heat required; and in doing so those occupying the outer ranges of comb, being in a sluggish state from the influence of the cold, failed to pass up and around the combs quick enough to keep up with the receding cluster, hence were left to perish with the cold. To obviate this loss, winter-passageways through the center of the combs were recommended, made by boring holes through them, or by having a curled shaving, which was painted on the inside, suspended in each frame when the swarm was hived, so that the bees would of themselves leave such passageways when constructing their combs. By this means the outer bees had direct communication with the cluster, so that, even though partly stiffened with the cold, they could easily recede so as to keep up with the main cluster. The painting of the inside of the shaving was said to keep the bees from building comb in these holes; but, notwithstanding, the bees would, as a rule, fill up these winter-passageways, each summer, which gave a good yield of honey, so it was found quite a job to see that they were open each fall. This led some one to propose boring a hole in the side of the hive, at the proper place, so that with a square stick, pointed at one end, which was to be slowly "wormed" (so as not to kill the bees) through to the opposite side of the hive, thus making a passage through all of the combs at one operation, thus making quite a saving as to labor. Many of my older hives have such a hole in the sides, with a button to turn over it when not in use; and where such passageways are desired, probably there is no better way of securing them than this last.

However, it was soon found that the bees would remain and die within half an inch of these holes in the combs; and as said holes were quite a damage to the combs (the bees filling them with comb having the drone size of cells the next season, or, if left open, it allowed a place for the bees to stay in when they were being brushed off for extracting or any other purpose), the making of such passageways has been generally given up, I believe. Some who still cling to the idea use what is known as the "Hill device" above the combs, as a sort of compromise; but after careful experiments with all of the above the writer has discarded the whole of them, believing there is not enough gained to compensate for the trouble. That the bees would die within an inch or less of such passageways, as spoken of above, and that such death of bees rarely occurred except during the first heavy freeze each fall, led me to investigate the matter closely, said investigation proving to my mind that these bees died from lack of vitality (or old age), rather than from the cause assigned. Usually we have much cool cloudy weather from two to four weeks before the first severe cold, so that old bees do not leave the hive to any extent to die, as they do all through the summer months, so that the number of dead bees dying from this cause would be considerable, providing none were chilled. But instead of dying at once, at this

time of the year, these old bees seem to linger along for a chance to get out of the hive to die, the same as they do at all times when they can fly freely, and so gather in little clusters of three, six, twelve, or more, in a place where they remain in a half-dormant state till caught by extreme cold, or a chance is offered for a flight.

I find, by referring to an old diary that was in writing at the time I was conducting experiments along this line, that one year, when a fine warm day occurred just before the first very cold weather, on which day the bees all flew finely, owing to their being confined to their hives from cool rainy weather for two weeks preceding, I found multitudes of sluggish bees clinging to the sides of the hives, on the grass, fences, etc., near the evening of that day. On touching them they had life enough to thrust out the sting, but none would fly or even crawl; and when the next morning came with a temperature of only 15 degrees above zero these bees were frozen stiff, remaining where they were the night before. This was a surprise to me, and I was led to believe, which belief still clings to me, that I had discovered the real cause of the trouble. A look into the hive after this cold wave had passed brought to light no dead bees on the combs as are usually found where the bees have no chance to fly for some time before the first extreme cold, and very few were found at any time during the winter, all getting clustered compactly for winter without passageways.

Then, again, I have often noticed that these little knots of bees were found, dead or otherwise, only with the first contraction of the cluster, as afterward no gain in dead bees between the outer ranges of combs was noticed with each expansion and contraction. Therefore I do not pay any attention to passageways for bees during winter at the present time.

#### DEEP-CELL FOUNDATION TESTED BY EUGENE SECOR.

*Mr. Root:*—Last spring you sent me for trial six pieces of deep-cell foundation. They were about 2 inches wide, and long enough to reach from side to side of a  $4\frac{1}{4} \times 4\frac{1}{4}$  section. I put these six pieces into two-inch-wide sections, and the sections in the center rows of a super covering an eight-frame hive. The remainder of the sections in the super had Vandusen flat-bottom-foundation starters, about three-fourths full.

The super was put on a strong colony July 7, with the intention of catching the basswood flow, which was soon to open. But we got no honey from that source. The only resources left were the last days of white clover and the

fall flow. The sections were entered by the bees very slowly. I think the deep cells were first occupied, but the comb-building progressed simultaneously on the flat-bottom foundation just as fast as in the sections which contained the new-process foundation. When taken off, all the sections containing the deep-cell or drawn foundation were well filled, and all the other sections *on one side of the super*. On the other side, right up to the deep-cell sections, nothing whatever had been done.

Now for the mouth test. As I said, the pieces used were not to exceed 2 inches wide. The rest of the comb in the sections was built by the bees. I would cut a small mouthful from the top, and then one from the bottom of the section, and eat them alternately. If I had been blindfolded I could not have told one from the other. Others tested it in the same manner and with the same result. The lower part of the section was built with drone comb.

I find that the season and the abundance (or otherwise) of the flow of nectar has more to do with the thickness of the combs—in other words its “gobyness”—than the foundation, keeping in mind that only the thinnest foundation is fit for sections. The “waxiest” honey I ever ate was all the natural product of bees. I believe every observing bee-keeper has noticed the same thing.

Now, what of the future of this new-process foundation? I believe it is going to be a valuable thing for “bait” sections at least. What is puzzling me most is how to fasten the stuff in sections without melted wax. I don't remember to have seen your plan of putting it in described.

Forest City, Ia.

EUGENE SECOR.

#### THE NEW DRAWN FOUNDATION A DECIDED SUCCESS.

In the Oct. 1st issue of GLEANINGS you ask for testimonials as to the merits and demerits of the new drawn foundation. I must say that I used about 20 pieces of this foundation, using 2 pieces in most of the sections, as I believe in full sheets. I consider even this to be too small a scale to give it a thorough test. But, candidly, I do not hesitate to say that I think the new drawn process a big step in advance—so much so that I believe the comb-honey man can give an advance of 25 cts. per lb. in preference to buying the old style at 50 cts. I also desire to say that, in soliciting testimony in regard to the new drawn process, there has been an oversight in said testimony; viz., how much more is it worth per pound than what we have been using? Some who oppose it have said, “Too much of a gob of wax.” Let us see just a minute. Foundation that runs 10 ft. per lb. is what I have been using. I put this into the supers, and the bees proceed to draw it out. When it is drawn out to the same width as the new-process foundation, I find that both kinds are identically the same, and the same number of feet to the pound; consequently the same amount of “gob” in each.

I run for comb honey, and my neighbor runs for extracted. Why is it that he gets 2

lbs. to my one? Will some one who opposes the new drawn foundation answer this question?  
F. D. LOWE.

Rosedale, Cal., Oct. 8, 1897.

[While we are glad to get such reports, we do not want those who have had adverse experience to keep still. We have just as much room for one kind of testimony as the other. If *flat-base* deep-cell foundation shall prove to be a good thing in the majority of instances, what shall we say of the same product with *natural* base? This is what we expect to make; and, if we do not miss our calculations, we shall have it next season.—ED.]

#### A CHEAP HOME-MADE UNCAPPING-DEVICE.

Let me suggest a cappings-drainer that is inexpensive, and a complete success as we use it. I will commence to describe it from the bottom.

First a tin pan just large enough for an ordinary super to rest in.

The one we use is 4 inches deep, and provided with a screw-cap honey-gate. Set the super on it. Next take a tin-bound sheet of wire-strainer cloth, just large enough to drop inside the super and rest on the tin strips provided for the section-holders to rest on. Then we want a frame to rest on the top of the super (as on the Dadant can), to rest the comb on while uncapping.

Now we will uncap till our strainer cloth is covered to a sufficient depth, when we will lay on a shallow tin pan—say  $\frac{1}{2}$  inch deep on one end and the sides, and at the other end enough deeper to give the pan quite a pitch (the projection, you will notice, will hang in the rabbets at the end of the super). The pan has a  $\frac{3}{4}$ -inch hole punched in it at "A."

Next put on another super with wire strainer, and continue your work, when the honey will drip through on the shallow pan, and, passing down to its lower end, will run through the hole "A" into the pan below. This, you see, can be carried on indefinitely, adding a shallow pan, super, and strainer, as needed, giving the maximum amount of strainer room at small cost, and in very compact form. The holes "A," you see, will come over each other if the precaution is taken to hang all the shallow pans the same way.

We were unable to get wire strainer on short notice, and for a makeshift made sieves of the ordinary window-curtain strips that would just fit inside the super, then stuck 4-ounce tacks  $\frac{1}{2}$  inch apart all round the lower edges, wound twine around them, joining a warp the longer way, next wove it across by the aid of a wire hook; drove the tacks home on the string, and then covered the tack-heads with a  $\frac{1}{4}$ -inch-stick strip. This makes a good substitute for the wire strainers, but is quite a job, and I imagine you could furnish the tin and wire strainers just as cheaply as these substitutes can be made.

I don't know that I have made the idea

clear. If you catch it I think you will see the utility of it, as it gives so much strainer surface with so little exposure of the cappings to flies or dust, and at so little expense to any one who already has the supers.

Emmetsburg, Ia.

J. C. BENNETT.

[I can't see the need of so many extra strainers and pans. One pan and strainer ought to be enough. Sufficient room for the cappings could be obtained by putting on extra supers.—ED.]

#### THOSE NAUGHTY FARMER BEE-KEEPERS; AN EXPERIENCE DIFFERENT FROM ABBOTT'S.

Dr. Miller, in Straws for Oct. 1, asks all those who have had to sell their comb honey at low prices on account of farmers and small bee-keepers bringing in their sickly-looking honey, to hold up their hand. Here is mine. Mr. Abbott's friends are not the kind I am looking for. Those farmer bee-keepers who put on sections one year and take them off the year following, and then take them to town and sell for what they can get, are surely enemies to the bee-keeper who tries to produce only a first-class article. It not only lowers prices for the good honey, but I have found some stores that will not handle honey, because they had got some of this leaky honey, and it ran all over their showcases, and smeared every thing up, and only a bee-keeper of experience knows it is not very easy to clean it up; and this is enough to put almost any store against handling honey at a small profit. I have sold all my honey at 10 cts., nice comb honey at that; but this is better than shipping to commission houses and receiving 7 or 8 cts. per lb. for it. My crop was about 2000 lbs. this year—about half clover and heartsease. Sweet clover did not yield much this year, as it was pastured too closely.

G. E. NELSON.

Bishop Hill, Ill., Oct. 15.

#### OVERSTOCKING IN YORK STATE.

*Mr. E. R. Root*:—In your editorial on page 672, under the heading "What I saw in York State," you give us to understand that the portion of the State visited by you seemed to be overstocked with bees, which is undoubtedly true; but in this part of the State just the opposite is true. To illustrate: In driving recently a distance of twenty miles from my place, and the same back, by another road, I think I did not pass more than a dozen hives, and they were box hives. The trip was near the St. Lawrence River and Thousand Isles, where honey has retailed at from  $12\frac{1}{2}$  to 18 cts. per 1-lb. section. I have wholesaled extracted honey in this market this season at not less than 40 cts. per quart, including can. I bought the honey of The A. I. Root Co. You may conclude that bees do not do well here; but a woman living near tells me that she had one colony increase to nine, in a single season, by natural swarming.

I keep only a few bees, but have taken  $128\frac{1}{4} \times 4\frac{1}{4}$  sections from a single hive in a season, and allowed them to cast one swarm. In

the same year, 1893, 10 colonies increased to 28, and gave 983 sections of surplus. This year five colonies have increased to 13, and given about 400 sections. I believe there are excellent localities here for the location of apiaries, and will answer inquiries from any one interested who will inclose a stamp.

J. F. PETRIE.

Plessis, Jeff. Co., N. Y., Oct. 6.

GENERAL MANAGER SECOR'S STATEMENT TO THE DEPARTMENT OF AGRICULTURE.

*Mr. Root:*—I noticed in last GLEANINGS that you had written to Wedderburn, of the Department of Agriculture, in reference to food adulteration and a remedy therefor. That puts me in mind of a letter that I addressed to the same person Oct. 15th, a copy of which I inclose herewith.

I learned somehow that the Agricultural Department was taking up this subject of food adulterations, and I addressed the above-mentioned letter for the purpose of opening correspondence, and to learn what we could do as a society in bringing about reforms through the cooperation of the Department. It was my thought that, if the Department is making a chemical study of honeys, we might get specimens analyzed free of cost. I have not yet received a reply to the inclosed letter; but if I do, and it is favorable, I shall follow it up.

This is simply to let you know that I am not indifferent to the interests of the Union.

EUGENE SECOR.

Forest City, Iowa, Oct. 20.

*A. J. Wedderburn, Chemical Division Dep't of Agriculture, Washington, D. C.*

*Dear Sir:*—I am informed that you are making special investigations as to the extent and character of the adulteration of foods in this country. The association named at the head of this letter, and which I represent, is especially interested in measures to prevent the adulteration of honey—more specifically, extracted honey. I should be glad to receive your cooperation in ascertaining to what extent extracted honey is adulterated, as found in the markets of the cities.

It is our hope to obtain legislation wherever needed in States or what we would think much better, by Congress, in the interest of pure food. We fear that there is a good deal of adulteration of the honey product by the admixture of glucose, which is probably the only adulterant that would make it profitable.

If, in your investigations, you are authorized to take up the subject of honey, I should be glad to correspond with you further in regard to it.

Yours truly,

EUGENE SECOR.

Forest City, Ia, Oct. 15.

*L. F. H., Pa.*—I can not tell you whether the blossoms of the coffee-tree of commerce yield honey or not. Can any of our subscribers give us any information in regard to this?

*S. K., N. Y.*—I would advise you to advertise your bees in some local paper.<sup>6</sup> On account of the express charges, and the difficulty of transporting to a distance alive, we

recommend disposing of one's bees in one's own locality if possible.

*P. D. S., Ohio.*—I think you will be able to have your queens fertilized this season. The drones will be present for some little time yet. Queens not fertilized this fall will stand a good chance of mating next spring.

*E. F. T., Mich.*—Candidly, I doubt very much whether it would pay you to put any ointment or cure for bee-stings upon the market. Most bee-keepers care very little for the stings. The best thing I know of is to remove the sting and then grin and bear it. The more one tries to doctor up the stings the worse he usually makes them.

*C. O., Wis.*—Replying to your inquiry of a late date I would state that I would not pay over \$2.00 for a colony of hybrid bees in a box hive. Such colonies have been bought many and many a time for from \$1.00 to \$1.50. Nowadays the hive, if of modern construction, should be worth at least as much as the bees. A box hive is worth practically nothing. For transferring, see instructions given on page 32 of our catalog.

*W. J. H., S. C.*—By white pine I mean lumber from pine-trees in the North. The pine of the South is apt to be pitchy, and is much heavier per square foot than the pine of the North. I recommend white pine because it is easier to work, easier to handle, and much lighter to lift. Of course, the heart part of these southern or northern pines is better than the lumber on either side of the heart.

*W. M. P., Ohio.*—I should be inclined to think from your letter that the bees had something in the hive which they regarded as a queen. It may be a fertile worker, it may be a virgin queen, or it may be a laying queen which is so small and dark that you would not be able to recognize her. I would not advise you to give this colony to another hive of bees. Give it a frame of eggs and brood if you can find any in your apiary. If they build cells you may know they are queenless. In that event I would advise you to unite them with another colony. Cage the queen, before introducing her, in the regular way. The main thing is to make sure the colony is queenless before attempting to unite; and if they build cells before giving them larvæ or eggs, then that settles it.

*J. W. S., Ky.*—It is so late now (Oct. 14) that I would not advise you to transfer by the short method described in our catalog. You'd better use the old method, or the one that involves cutting out the combs of honey and brood, and fitting them into the brood-frames themselves. Of course, you would need to pull apart the old box hive, or whatever they happen to be in. For directions in regard to this method of transferring, see any of the text-books, and especially our A B C of Bee Culture.

Bees will build combs at this time of year—that is, providing you give them frames of foundation wired, and feed them; but the weather needs to be warm, and you should have had some previous experience in feeding

bees. Perhaps, taking it all in all, it would be better for you to wait till next spring before you transfer. If you do not change to the other hive, you would need to make sure that the old one has stores enough to carry it over till next spring.

ON the afternoon of the 24th of October there arrived at the home of the editor of the *American Bee Journal* a beautiful baby girl. Both mother and daughter seem to be doing well. We extend to Bro. York our heartiest congratulations. Give the baby a kiss for us Medinaites.

THE writer or editor who furnishes the matter for "Beedom Boiled Down," in the *American Bee Journal*, is doing some good work. The items are not only carefully sifted, but clearly and forcibly put. I think I recognize, not the handwriting, but the earmarks of the writer.

INFORMATION has come to us that J. H. Martin, so well and favorably known to our readers, is now very sick. We hope the report is either not true or else that our friend the Rambler has passed the danger-point. J. H. Martin was first heard of in York State. He then became known to the bee-keeping world as an inventive genius. Later on he began rambling through the East for GLEANINGS, and his articles appeared in these columns. His rambles among bee-keepers extended finally across the continent to California. Later on a serial story, so fresh to all our readers, came forth from his pen.

J. H. MARTIN.

#### NIVER AND HIMSELF.

AMONG the bee-men whom I met recently in York State was S. A. Niver, to whom I have already referred as being the chap who had a tongue that was "balanced in the middle." Well, with this facile tongue he knows how to sell honey, and get bigger prices, I am told, than almost any one else, even selling the same goods. Mr. Niver generally styles himself "Morton's brother-in-law." Morton, you know, is the *bee-keeper*, that inventive genius to whom I have already referred, and it is he who *produces* the honey. It is Niver who *sells* the goods.

It is with peculiar pleasure that I introduce to you in another column "S. A. Niver and himself." Among Niver's other accomplishments is guitar-playing; and the picture elsewhere shows him not only playing the guitar

but looking at himself in another chair. In other words, Mr. Niver appears to be one of those remarkable chaps who are able to do two things at once—sit in two places at a time—that is to say, in this case at least, is able to assume the *role* of beginner in guitar-playing and instructor in the same art at one and the same time.

I need hardly say this is accomplished by a trick in photography. Two "exposures" are taken on the same plate. When the first sitting is taken the negative in the camera is covered with black paper, just half way; then an exposure is taken on the uncovered end. A second exposure is then made, but the other end of the negative is then covered.

Mr. Niver, besides being a glib salesman, is a real fun-maker. To illustrate: At one of the county bee-keepers' conventions which I attended, while we were enjoying the picnic dinner a certain young man had just delivered a "drive" on his friend Niver. Quick as flash, Mr. Niver, with eyes beaming with earnest sympathy, turned about and said to the rest of us in a confidential tone, "Oh, yes! Harry is an awful good boy. He has only one fault. When he eats pie he *will* muss his ears;" and Harry was eating pie just then. Of course, this raised a roar of laughter.

#### FOUL BROOD INCREASING IN THIS COUNTRY.

WE are receiving, almost daily, suspected samples of brood which we are requested to diagnose. In nine cases out of ten they prove to be foul brood. To-day (Oct. 20) I opened a sample of one of the worst cases I have ever seen. The odor from a colony affected would be sufficiently strong, I think, so that it could be detected several yards from the apiary. At all events, it was the "loudest"-smelling sample I ever came across. This almost daily receipt of samples of affected brood from all parts of the country is alarming.

I have already found where this disease is making headway in portions of the United States that have more colonies and more bee-keepers to the square mile, I believe, than any other place in this country. In fact, the disease is apparently starting up all over the land, and it will need some vigorous measures and some good legislation to keep the disease in check. I would suggest that, in those States where there is no foul-brood law, bee-keepers send in a big petition to their next general assembly, asking for the needed legislation.

A foul-brood inspector (N. E. France, of Platteville, Wis.) has been appointed for Wisconsin. A law was recently enacted; and with the State back of him the inspector proposes to make a clean sweep of the State.

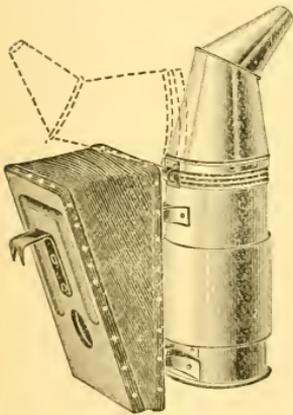

The good work done by foul-brood inspector McEvoy, of Canada, is too well known to need mention, and now the Canadian bee-keepers are practically masters of the disease.

We on this side of the line can not afford to let it get the start of us. Our catalog, our A B C book, and, in fact, nearly all of the text-books on apiculture, give good methods of treating the disease.

In the mean time, let the friends continue to send in samples of foul brood securely wrapped in paraffine or greased paper, and packed in a tin box. A wooden box securely nailed, and water-tight, will answer in lieu of a tin box if that can not be obtained.

A SMOKER-HOOK—A COUPLE OF COGGSHALL'S IDEAS.

WHEN I was at W. L. Coggshall's he showed me the convenience of having a hook placed on the back of a smoker in such a way that the smoker could be caught on to the edge of the hive while the operator is at work over it. Mr. C. explained that it was a waste of time to have to stoop down to the ground to pick up a smoker that, in nine cases out of ten, would be tumbled over on its side, and burning at a very low ebb. He would have a smoker within a few inches of the hand, "right side up with care," and the draft fully on. The hook is a piece of strap iron, bent in the form shown, and fastened to the top of the smoker-bellows. The cut below shows the idea:

is at work it stands attached to the top edge of the hive or of the cart, up in the air, it can be seen anywhere in the apiary.

Many and many a time I have lost track of my smoker; and in order to find it I have had to peer around all the hives, and finally succeeded in locating it on its side in an obscure place, half gone out. I do not know but we shall have to supply our smokers with hooks next year. They would be put inside the fire-cup, and the bee-keeper can attach them or not as he chooses. Those who already have old smokers can make hooks and put them on this winter.

Incidentally it will be noted that the smoker bellows-boards above illustrated are grooved around the sides and top edge. The purpose of this groove, as I have before explained, is to enable the operator to get a better grip on the smoker. When the fingers are wet with perspiration or honey, sometimes the smoker will slip out of the hand. But this groove entirely prevents it. It will be remembered that Mr. Coggshall some time ago recommended cleats; but it seemed to be better and far neater to

have grooves; and these we have put on all our late-made smokers.

A BEE-HUNT AT MEDINA.

DID you ever go out on a genuine bee-hunt—the good old-fashioned kind that our fathers and grandfathers used to tell us about? About a year ago, hearing that a bee-tree had been discovered a mile or more east of Medina, I determined that I would have some of the fun I had heard so much about. Two or three of our shop boys were invited to go along. No, come to think about it they invited *me*. Implements? Yes, we had lots of them—axes, a large crosscut saw, veils, dippers to dip up the gallons (?) of honey; smokers, honey-knives, and every thing else galore, besides a horse and wagon. The horse was warranted to be sting-proof, and not to run away.

We had previously obtained the consent of the owner of the tree to cut it, and the afternoon was "just lovely." Two of the boys went crosslots on foot, taking along a gun, while the rest of us rode. For fear that I might miss an opportunity of getting a fox squirrel I took along my double-barreled hammerless; and that I might be able to preserve in permanent form some of the exciting incidents of the bee-hunt, I took the camera that makes many of the pictures for GLEANINGS. Arrived at the bee-tree, the boys pointed out where the bees were located. I squinted and looked, and looked and squinted, but could not satisfy myself that there were any bees in that tree. As my shotgun was conveniently near I thought of a little scheme. I would fire at the place where the bees were supposed to come out. Perhaps that would stir them up, and it did; but—"Whewation, boys! see that big fox squirrel!" I shouted. I was seized with the "buck-fever," and never once thought of letting him have the other barrel till too late. The squirrel seemed to me to jump from the very hole where the bees were. I had expected bees, but not game. Well, as he disappeared in another tree we pursued after him. My shot had called the other man, and we together went squirrel-hunting, leaving the bees to make things interesting for the other fellows. After we had hunted a while we came to the conclusion that Mr. Fox had found another convenient hole. We gave up the search, and came back to the bee-tree.

Two of the men—one of them Mr. Dannley, who makes the foundation-rolls, and the other one Mr. Hammer, who has been working on the Weed deep-cell dies—were at work sawing the bee-tree down. I laid the gun aside, took up the camera, and took a "time exposure."

Perhaps some of you do not know how our Ohio woods look in the month of September. Elsewhere in this journal you will see the bee-tree, and just at the foot of it the two men with the crosscut saw. The place where the bees were located was just above the crotch of a limb broken off very near the top of the picture, on the left-hand side of the tree.

We all took turns with the saw and with the ax. Some of us were not very expert with the last-named implement. I noticed that, while I chopped, the rest of the crowd departed to a

distance. Notwithstanding this, between us the tree began to show evidences of falling. Anticipating a big skirmish when it should fall, we put on our veils and lighted the smoker. A few more blows of the ax, and the monarch of the woods began to totter and fall. Down it came with a *cr-a-sh*! It was a little lively around the knot-hole where the bees were coming out; but after we began chopping and sawing again to get at the heart of the tree where the bees were, they quieted down.

Just about this time we heard the chattering voices of schoolchildren echoing in a distant part of the woods. In a few moments more, greatly to our surprise we found ourselves surrounded by a whole school of children, who, hearing that we were going to cut down a beehive, had come to see the "fun." The schoolma'am, who was doubtless equally anxious to see some of the same sport, readily consented to dismiss school at an earlier hour. The bees had now quieted down, and the children became bold enough to cluster around the log where we were at work trying to scoop out the bees and honey (?) with a dipper. There were combs in plenty, but little honey.

Just about as we had finished our task and passed around several hunks of the delicious morsel to the owners of eager eyes and hungry mouths, I set up the camera again and took another shot. In another view elsewhere you will find the result. The most remarkable thing about the whole picture is that the children are bareheaded, barearmed, and in some cases barefooted, while *we professionals* had veils on and smokers in our hands to prevent getting stung: I did not realize the incongruity of the situation till too late. Then with as much grace and ceremony as I could command I offered my veil to the prepossessing schoolma'am. But this she kindly declined. I then offered it to some of the older girls, but with a like result.

Did any of the children get stung? Only one of the boys, I believe, who, while astride the log, looking into the cavity, happened to sit upon an unlucky bee. We all knew the *precise* moment when the sting pierced his pants, you may be sure.

The significant fact is, that those of us who wore veils were stung more than the children, and the reason is very evident. When bees are demoralized by pounding, as by the chopping open of their cavity, they seem to lose all desire to fly and sting. They just crawl and crawl, and crawl up under the veil, and, failing to get out, sting.

Some little time ago a lady wrote a story which was submitted to us for consideration, on the subject of bee-hunting. She went on to state in this story how angry the bees became while the tree was being cut open; how they took possession of the land for miles around; how it was not safe for man, boy, donkey, or chicken to be anywhere near that vicinity, and how cross the bees were for days afterward. When I had finished reading that story I came to the conclusion that *that* writer had never had any experience in bee-hunting.

Did our bee-hunting experience pay in bees

and honey? Well, hardly. All the honey we secured was eaten by the aforesaid schoolchildren; and the bees—well, there were about enough to cover perhaps two combs, and before winter they simply died. That they would have died anyhow from lack of stores had they been left in the tree relieved our consciences a little. But in experience and "piles of fun," as the boys said, we were repaid richly.

#### THE NEW STYLE OF SEPARATOR AND SECTION; THEIR IMPORTANCE.

SINCE the pages of "Stray Straws" were "made up" we have received another Straw from Dr. Miller, which, in order to get in this issue, I insert right here:

THE NEW PLAN of sections and separators, as mentioned, p. 744, has interested me more profoundly than any new thing in bee-keeping for some time. I've hardly settled down to a fixed opinion yet, but I am thoroughly interested. A principal question with me is that of cost.

It is evident that the doctor, at the time he sent the Straws, hardly knew what estimate to put on the new devices; but the more time he has had to think of it, the more "profoundly interested" he has become, and I think this will be the experience of thousands of others.

The doctor need have no fears as to cost. The separators are all made of scrap that has heretofore been burned; and as to putting the pieces together, that will be done by means of automatic machinery in the factory before the separators are sent out.

The reader will be interested to note what Julius Tomlinson, J. A. Golden, and A. I. R. say in this issue regarding these same things. Of late years our senior editor has somewhat lost his interest in bees, or, at least, has been compelled to turn his attention to other matters; but when I showed him the new style of separator and section, and explained their merits, his face fairly glowed with enthusiasm. He was also "profoundly interested," as will be evident by what he says elsewhere.

I do not know but I may be mistaken; but I believe the introduction of the new separator and section will be a great step in advance, and that the time will come when other styles of sections and separators will be largely superseded. The fellow that doesn't get "in the swin" next year will be the "worse" by a cent or two per pound for his comb honey, I fear.

#### ANOTHER BEE-BOOK FROM THE DEPARTMENT OF AGRICULTURE.

"BEE-KEEPING" is the title of another bulletin from the United States Department of Agriculture, by Frank Benton, Assistant Entomologist, that has just been issued at the government printing-office. It contains 32 pages the size of this, is printed in bold, clear-faced type, and is illustrated with suitable engravings. When the other bulletin was issued, the supply was exhausted in a very short time, and it became necessary to charge a small price in order to prevent the edition from being entirely exhausted. But it seems

that, since that time, there have been frequent inquiries for information on matters pertaining to bee culture, and accordingly another more abridged book has been issued, and it is reasonable to suppose that this time the supply will be equal to the demand. The Entomologist, Mr. Howard, says: "Though it has been designed by the author primarily to answer a few of the specific questions which are most likely to present themselves to the mind of the inquirer wholly unfamiliar with the subject, the aim has also been to introduce in the treatment of the various topics information which it is hoped will lead many of longer experience to more successful methods than they have yet practiced."

The book, although brief, seems to be a complete text-book on apiculture; and as such I have no doubt it covers the subject in an admirable manner. The contents, as given on the first inside page, are as follows:

Locations suited to the keeping of bees; returns to be expected; all can learn to handle bees; to avoid stings; hive to adopt; swarming; dequeening; requeening; space near entrances; selection in breeding; special crops for honey not profitable; plants and trees for honey and pollen; to obtain surplus honey and wax; comb honey; grading and shipping comb honey; production of wax; wintering; general considerations; loss of bees through disease and enemies.

As I understand it, this work will be sent free to any who will apply for it. Make your request to the Department of Agriculture, Washington, D. C., asking for Farmers' Bulletin, No. 59, entitled "Bee-keeping."

#### THE ILLUSTRATIONS IN THIS ISSUE.

The reader can scarcely fail to note the wealth of illustrations in this number, both in variety and in general excellence. Some of these pictures I took myself, and it is with peculiar pride that I show our readers some of my own work.

On my eastern trip last summer among bee-keepers I took a large number of photos with my large-sized folding Kodak. Some of the pictures I have already given, and there are quite a large number more that I expect to present later on.

Did you ever think that a picture will very often give to the reader in a moment of time information that it would require pages and pages of descriptive matter? Perfection in modern photography and half-tone engraving enables modern progressive journals to give their readers not only delight but real information, without the medium of a single word of language. I expect to show in next issue why honey in no-bee-way sections looks better.

#### A NEW IDEA — NOT GRADING-RULES, BUT PICTURES TO SHOW EACH SEPARATE GRADE AS IT SHOULD BE.

AN idea has occurred to me in the matter of grading honey, and it is this: Let there be a committee appointed by the next U. S. B. K. U. meeting to make one, two, three, or four grades of honey from some lots that may be

brought in by the bee-keepers, or that may be purchased in the open market. They are to pick out, say, four representative sections that they would call "Fancy," and put them in a lot by themselves; four other sections that they would call "No. 1," and still four more that they would call "No. 2." Each section in the several groups should present as much variation as the grade itself will allow. That is to say, sections in the No. 1 grade, for instance, can't all be alike or equally good; but the picture of No. 1 should show the *limits*.

Now let there be a photo taken of each of the lots, "life size," said photos reproduced in half-tone, and printed on neat cards, each card to be labeled "Fancy," "No. 1," or "No. 2," respectively.

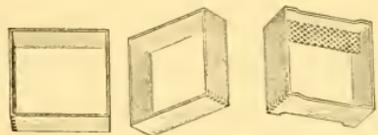

You see the point. A picture will describe at a mere glance what a body of bee-keeping experts would regard as extra fancy, as No. 1, No. 2, and so on. The trouble with the ordinary grading-rules is that *language* is not adequate to describe the limits of fancy, No. 1, etc., and hence arise the confusion and general dissatisfaction.

This suggestion came to me while I was at the apiary of Miles Morton, in York State. His brother-in-law, Mr. Niver, showed me how he would grade his honey, and placed the sections in four different lots. Of these I have secured a nice photo, and Mr. Niver will, later on, be able to show you just how *he* grades honey.

#### THE EVOLUTION OF THE SECTION HONEY-BOX; THE PROBLEM OF LETTING THE BEES IN AND LETTING THEM OUT.

I THINK I have heard of a religious sect, or perhaps it was a sect without any religion, who placed *man* at the head of creation—not only at the head of things earthly, but at the head of the universe, ruling out God. Well, there is considerable to admire about humanity, I admit; but, oh dear me! if I were to accept the doctrine that man is the highest order of intelligence to be found in this whole wide universe—well, it certainly would be awfully sad. In fact, I have sometimes thought that, if a premium were offered for stupidity and bungling, humanity at its best might take the prize from all animal kind.

The above reflections were suggested when the boys showed me an improved honey-box or section. What do you suppose it was? Why, it was a little square frame, as shown in the picture below—the one that is smooth and level all around, without any openings for the bees, or any thing of the sort. The first

THE OLD AND THE NEW 1-POUND SECTIONS. honey-section I ever made (8 to fit into a Langstroth frame) was of this description. You will find a picture of it on the front cover of GLEANINGS for September, 1876. We

already had foundation to get the bees to build their comb true inside of the sections; but, of course, a honey-box must give the bees access. I at first decided to move my wide frames, each one holding eight of these sections, a little way apart so the bees could get in all around; and, in fact, our first section was a brood-comb full of sealed honey composed of eight little frames so they could be taken apart and sold. In a little while we had sections touching each other, or closed, at the sides, but open at the top and bottom. Doolittle and Capt. Hetherington first used this style, if I am correct. Some of them had simply a narrow bottom-bar, and were closed all the rest of the way round. Finally the bee-keepers of the world settled down on a section closed at the sides but open top and bottom; and for nearly twenty years these have filled our markets, or something similar. It is true that some inventive geniuses (Danzonbaker among them) made sections not touching each other the *whole* length of their perpendicular sides; and in this manner they secured sections of honey without little holes being left in the corners.

Separators were *long ago* decided to be a necessity. Then somebody said they were *not* a necessity. Then we came back to separators. We had them of tin, wooden veneer, wire cloth, perforated metal, and perforated wood; and the shapes and forms were so great and curious that a volume might be written in regard to separators. I do not know but we had the separator figured below.

A WOODEN SEPARATOR MADE OF SLATS.

This separator is made of thin strips of bass-wood, polished and sandpapered. It has panels in each side like a portable fence. In fact, I believe the boys have decided to call it the "fence" because it is a shorter word than separator. The openings in this separator are in width about the same as in the perforated zinc. The up-and-down slats on each side of the separator are also of about the thickness of these perforations, or  $\frac{1}{8}$  of an inch. This fence is made very accurate by means of ingenious and perfect machinery. When the smooth planed sections are put into the cases, this separator brings every thing to a small fraction of an inch just where it ought to be. There is very little scraping or cleaning to be done. The box is smooth all round. In fact, you can sandpaper its edges after it is filled with honey, without much danger of injury. When the sections are packed up for shipment, the honey in one section never bumps that in the next one, for they are exactly alike; and yet they pack up so close and solid when crated for shipment that each cake of honey almost touches the honey surface of its neighbor. There is no waste of room.

Let us now go back to my starting-point.

After twenty years of studying and experimenting, trying devices not only sufficient to fill the Patent Office buildings, but after having made experiments so varied that great volumes would be needed to record them, we come back to the place where we started. These experiments in this research were not made by only a few persons, but *thousands* have studied over the problem for years, and racked their brains far into the small hours of the night; and yet it would seem just now as if it had amounted to almost nothing—at least, my impression is, after having seen the honey in these simple sections, and after having looked over the apparatus for producing it, that it must very soon take the place of all other styles of sections.

Now, I know full well, dear friends, that this style of section is not new. In fact, I said so at the outset; and, so far as the separator is concerned, a good many bee-keepers—our good friend Oliver Foster prominently among them—have used and advised a separator almost like this one.

As I grow older, and look back, I am reminded that this queer experience in bee culture is not an isolated case. Electricity furnishes many such examples. Forty years ago we were very near electric locomotion. When your humble servant, *more* than forty years ago, traveled from town to town exhibiting an electric motor, he predicted to the good people who came out to hear him talk, that, in a very short time, electricity would supersede steam as a means of travel. His prediction looks *now* as if it might come true. But he had to wait over *twoscore* years before inventive genius got round to it. Shall we be disheartened? God forbid. Let us, rather, roll up our sleeves and do the best we can. Blundering keeps us busy; and if we do it with the love of God in our hearts it *makes us happy*; and in *due* time we *shall* reap *if*—we faint not. A. I. R.

#### THE SENECA COUNTY BEE-KEEPERS' PICNIC AND BEE CONVENTION.

AMONG the counties where bee-keeping flourishes, and where honey is produced by the ton and by the carload, is Seneca Co., lying between the beautiful lakes of Seneca and Cayuga—two lakes whose length is about forty miles, with width ranging from three to five. It is in this section of country, especially along the shores of these lakes, where immense quantities of beautiful fruit are produced, and bees and bee-keepers—they are almost as thick as the fruit-men.

Along in August I received an invitation from the secretary of the Seneca Co. Bee-keepers' Association, Mr. C. B. Howard, to be with them at their next meeting at Elm Beach Park. If I would promise to come they would arrange the date to suit my convenience. As I was going through that part of the State I very gladly availed myself of the pleasure of meeting so many York State Bee-keepers all together. Accordingly, on the 31st day of August I met them, as per appointment, at Elm Beach Park, on the shores of Seneca Lake.

Owing to some bungling on the part of the

railroad company, my bicycle had been carried in a baggage-car past my destination; and when I arrived at Romulus, the nearest railroad station, some seven miles distant, I was without means of getting to the bee-keepers' picnic in time. A horse would be too slow. I finally hunted around and found a blacksmith who was working for Mr. Howard's father-in-law, who knew that I was going to that picnic. I was afraid that I could not identify myself satisfactorily; but he accepted my story, and told me to take his wheel, and welcome. With this I managed to get down to the picnic grounds in time to meet the bee-keepers, but not in time to enjoy their bounteous dinner. Arriving there, the president, Fred S. Emens, introduced me, all sweat and out of breath, to the company there assembled, and then added that I was expected to take up the rest of the time of the convention, after which we would take a little ride on a steam-yacht that would be at the landing ready for us.

I will not attempt to repeat what I did or

*Mr. E. R. Root:*—I find there are some faces which are not familiar to me, but will give you the names of those that I know, and will make an X for those that I can not recognize. I will commence at the tree on the back row. B. E. Bradley, Henry Hamilton, Mrs. T. T. Covert, M. W. Abbott, Mrs. Abbott, Mr. Sutton, Matt Sutton, W. F. Marks, Mr. Emens, J. B. Whiting, D. H. Townsend, Miss Townsend, Mrs. White.

Row 2.—Mr. Perry, Mrs. J. C. Howard, Mrs. Sutton, Miss Sutton, Mrs. C. A. Munson, Mrs. Asa Slack, X, Henry Manger, Chas. Baldrige, vice-pres.; Geo. B. Lamoreaux, J. W. Newman, Mrs. Newman.

Row 3.—Joe Haney, Mrs. W. E. D. Gibson, M. T. Williamson, Mrs. Bailey, X, X, X.

J. C. Howard, Mrs. C. J. Baldrige, D. R. Ambrose, Wm. Gilland.

Row 4.—B. F. Howard, H. S. Lyke, Asa Slack, C. B. Howard, Sec. and Treas.; Fred S. Emens, Pres.; B. D. Scott, Mrs. C. B. Howard, Mrs. B. D. Scott, Parker Brown, Ira Wilson.

Although there are shown only about sixty bee-keepers, if my memory serves me correctly there were something like a hundred present. When I got ready to take the picture, some had gone home.

It seems a little strange to us Westerners that single counties in York State could muster up more bee-keepers and more enthusiasm

THE SENECA COUNTY (N. Y.) BEE-KEEPERS' CONVENTION.

did not say to the bee-keepers that day relative to bees; but after the convention adjourned I craved the privilege of taking a photo of the company, and the result is shown herewith.

The president, Mr. Emens, with a section of honey in his hand, sits at the front; and Mr. Howard, the secretary, sits at his right, holding his four-year-old in his lap. At the left of Mr. Emens is Mr. B. D. Scott. A few days later, having lost my way, and seeing some bees across the roadway I decided to call and make some inquiries, never dreaming I should ever meet any one who knew me. A pleasant voice from around the corner of the house called out, "How do you do, Mr. Root?" This proved to be none other than Mrs. B. D. Scott, whom I had met a few days before. After looking over the beautiful honey and making a very short stay, I was directed on my way. But, to return.

I am not able to give you a list of the bee-keepers, and so I asked the secretary to furnish me their names. Here is a partial list, given me as he could remember them:

and more honey than whole States in the western and central parts of the country; but such seems to be the fact.

Ontario, bordering on the north-east, is another county that has now an international reputation from the fact that its county association, through one of its active members, Mr. W. F. Marks, also present at the convention shown above, first began the agitation in favor of *Apis dorsata*. You will remember that a resolution was passed, urging the general government to secure an importation of these bees. A request was also made of the North American, asking that association to pass a similar resolution. A full history of the whole matter is given on page 672. Well, Ontario also produces its tons of honey. Tompkins Co. produces more, if any thing, than either Ontario or Seneca. Then there are other counties like Onondaga, Otsego, Schoharie, and Albany that produce as much as some of their sister counties, but I shall have more to say concerning these and other counties at another time.

A VISIT TO THE OIL-REGIONS NEAR WASHINGTON, PA.

I have always been interested, not only in wells for water, but in wells that produce oil, gas, or, in fact, anything connected with the development and bringing into use of any of God's gifts that have been stored away for ages under the surface of the earth. When I found the following in the midst of a business letter, you may readily imagine I was somewhat interested:

*Friend Root*.—If you do not have sufficient excitement in Medina, come down to my place and I will take you all over the oil fields, and show you the new wells. We have one here that has produced 90,000 barrels in about ninety days, and it is close to some of my property.

H. W. VANKIRK.

Washington, Pa., Aug. 19;

Soon after receiving the above I took the train at our place, and reached Bridgeport between one and two in the afternoon. Notwithstanding I have lived all my life so near Wheeling, W. Va., I never before had caught a glimpse of the beautiful bridges that there span the Ohio River. May be the circumstances and surroundings had something to do with it; but it seemed to me then that that beautiful suspension bridge surpassed in grandeur and sublimity any similar structure I had ever seen at Niagara Falls or anywhere else; and while I was wondering whether it was really a paying transaction to make such a magnificent structure just to get across the Ohio River, I was reminded by a man at the entrance of the bridge that I had not paid my toll. How much do you suppose it was for going across? Just *one cent!* At the other end of the bridge you pay another cent to get off. But there are really two bridges. The first one strikes the island on which is part of the city of Wheeling; and then another bridge goes from the island over the main part of the river. At the St. Louis bridge, you may remember, I paid ten cents for going over with my wheel, whether I walked beside it or rode, the same price as for any other "vehicle."

When I got over to Wheeling I found myself on part of the same national pike that I described while going through Belmont Co. It runs over into West Virginia, and through to Washington, Pa. Others as well as myself enjoy riding over this beautiful national pike, for I found wheelmen and wheelwomen going and coming almost constantly. On this pike through West Virginia and Pennsylvania the L. A. W. have put up mile-posts at the end of every mile. This gives you information in regard to distances both ways to and from the prominent towns. Not only that, where there is a hill at all dangerous a conspicuous board neatly painted is put up as a caution to wheelmen. I think it reads something like this. First in large letters is the word "danger;" then in a few words below, the wheelman is

admonished of just the kind of danger he is to look out for at the foot of the hill. Now, it grieved my heart to find that a good many of these danger-boards had been smashed to pieces by throwing rocks at them, there being plenty of said "rocks" all along the national pike. This sort of vandalism is getting to be really a serious matter. I have actually got off from my wheel, picked up the fragments of a sign-board that had recently been smashed, and then in despair have gone several miles out of my way, and possibly been obliged to ride over a dangerous road after dark, just because of this fashion of destroying sign-boards as fast as they are put up. In our county I have noticed some very pretty ones made of malleable iron. But some of these iron signs have been twisted and bent up so you have to get off your wheel to see what they read. After a few boys have been severely punished, I think perhaps this sort of "sport" will be broken up.

The nearer I got to Washington, the thicker were the oil-well derricks until it really made one think of the masts of schooners in a crowded bay along the ocean-side. After night the whole country was illuminated and made cheerful by the blazing of gas-jets. Beautiful lawns with curved walks and shrubbery were lighted up at night by gas-jets two or three feet high. The gas seems to be so plentiful there it does not seem to be extravagance to light up not only the houses but the doorway yards and lawns.

I found my friend Vankirk at Vankirk Station, five or six miles from the city of Washington. As I rode up in front of his residence I found him and his hired man just getting ready to start out to work. (Of course, I stayed in Washington over night.) When I rode up to where they were busy in hitching up their team I said, "Good morning, boys. Do you suppose there is anybody around here who wants to see me?"

You ought to have seen friend Vankirk's face light up after he had taken in the situation. While he changed the order of business and called for a horse and buggy to take us around to the oil-wells I shook hands with the old father and mother, got acquainted with the children and grandchildren, looked over the strawberry and raspberry patch, took a glimpse at the apiary, gazed my fill at the tops of the great hills, and then away down into the valleys. Oh what hills they *do* have in Pennsylvania! And the funniest part of it is, they grow tremendous crops of corn, not only on the side hills, but over the very tops. They do not use fertilizers at all, if I am correct, and but very little stable manure, because they do not have it to use. But in some way or other they manage to get magnificent corn. As nearly as I could find out it is done by a system of rotation and plowing under of clover or timothy at regular periods.

The place where the great excitement has recently started up is away back in the hills, a good way off from "anywhere." Something like twenty wells have already been put down. Out of twenty, two were paying tip-top; three or four moderately, and a dozen or

more are almost dry wells. The gas and oil are found at a depth of from 2800 to 3000 feet. Enough gas has been found in the locality to run all the engines, and there is quite a system of piping to carry the gas to wherever a new well is being put down. Another system of pipes, to carry water, is also needed.

Before we reached the big well I was so used up by climbing hills that I told friend Vankirk I could not go any further and keep up enthusiasm until I had had my regular nap. We found a place where a new dining-hall had just been put up; and I tell you I had a real nice dinner with the well-drillers. I believe they are mostly rather rough in their manners and talk; but friend V. (you remember about the Sunday-school, building and all, that I told you he was largely instrumental in starting) found an opportunity at the dinner-table to discover one or more of the boys who had attended the revival meetings; and I tell you it was refreshing indeed to find even in that crowd that there were at least a few who loved the name of the Lord Jesus Christ.

I had a very refreshing nap in a new room made of rough pine boards; and before taking my nap it was my privilege to pray that the spirit of the Lord Jesus Christ might find a lodging-place in the hearts of those who were delving away down in the depths of the earth for these hidden treasures that God has placed there for his beloved children.

By the way, it seems a little queer that there are just as many wells, if not more, clear up on the tops of the hills, than there are down in the valleys. When we think of the extra labor required to pull timbers and great heavy iron pipes and massive drills up on to the tops of those hills, one might suppose that, so long as it is all guesswork any way, the prospectors and projectors would choose to locate in the valleys. I tried to find out by inquiry what it was that guided them in deciding where to sink a new well. It costs three or four thousand dollars to get down to the proper depth. As nearly as I could find out, they work this way: After a successful well has been struck, others locate around it—not getting too close, however. Now, suppose that oil-wells are failures except in a certain course from the first good one. Of course, the new ventures will be off in a similar direction to this second successful well. In that way they begin to lead off in a certain direction. The first well may be just on the edge of a good field. In that case, the question is to decide in which direction the *center* of the field lies. Now, in connection with the above facts the disposition of the party who owns the land adjoining has much to do with it. Some men will be exceedingly liberal in making terms for drilling test-wells. Others will hold off for better prices. So you see we have two factors to decide where a test-well shall be put down.

Along with the oil come gas and paraffine. The latter seems to be a substance that comes out with the oil, but separates, coating the tubes, the sides of the tank, and every thing else, with its grease. I presume one reason why the flow of any new well gradually sub-

sides is because of the accumulation on the pipes of a coating of paraffine.

The most important well of the group gave about 2000 barrels of oil per day, or pretty nearly that, when first opened; and for three months past it has averaged about 1000 barrels a day. When I was there it was giving some 600 or 700 barrels. But the oil comes intermittently. Some wells do not give oil at all except at stated periods. These periods may be once a day or once in three or four hours; and at times the pressure of oil and gas is so great that the iron pipes writhe and twist about like a snake as they discharge their volumes of gas and oil under the strain of a pressure equal to or perhaps greater than that in many steam-boilers.

Now, friends, there is something very enticing and even fascinating about starting up a new industry away back in isolated country places like this one. It is exceedingly refreshing (especially about *dinner time*) to find a brand-new boarding-hall, clean dishes, pleasant, nice-looking women, and every thing to indicate enterprise and go-ahead. It was pleasant to see the well-drillers doff their overalls, wash up, and sit down to dinner, with hair nicely combed, etc. It was the great well that was spouting forth its treasures, but a few rods away, that furnished the *money* for this enterprise. It is quite likely a town will be built up here, for the Standard Oil Co. has already run up a pipe-line to take away the oil. The wives and mothers will need to come into the neighborhood, and children's voices will be heard; and then, oh how *great* the need of a Sunday-school as well as day school, and a little church! And if these people expect to prosper and be happy, there will needs be a *Sunday* to be remembered and kept holy. May the great God above help our people, in starting things of this kind, to remember they can never be prospered and enjoy real happiness without *righteousness* and *godliness*.

## OUR HOMES.

---

---

Remember the sabbath day, to keep it holy.—EXOD. 20:8.

The following was read at a semi-annual conference at Chatham Center, Medina Co., O., Oct. 21:

THE CHRISTIAN SABBATH: OUR HERITAGE AS A NATION AND INDIVIDUALS.

Towering high above other blessings we have from the beginning of our nation a heritage of Christian principles; and who that thoughtfully contemplates the past but accepts as true the following words? "There is no heroism like that which comes from hearts filled with heavenly influences."

I am often surprised at the coolness with which many appropriate all the benefits of this government for themselves, and rail at Christianity, but for which there would have been no nation such as this has been in the past, and is now. I would suggest to them, if such be really their honest sentiments, that they make their dwelling in heathen lands, where they will not be troubled with the demands of the Christian sabbath. When we try to contemplate the beginning of our sabbath, the seventh period of time that God hallowed, we seem to stand awed amid creation's dawnings, and hush our breath to listen to the music of the spheres as the morning stars together sing, and,

echoing down the ages, there breaks upon our startled ear, "Remember the rest day, to keep it holy."

In the words of Daniel Wilson, "The sabbath stretches through all ages, affects all men in every period of time, distinguishes the true servant of God from the wicked, more than any other ordinance, upholds the visible profession of religion before the eyes of mankind, is the most direct honor that a man can pay to the name and will of the ever-blessed God, and will never cease in its authority here till our sabbaths on earth give place to that eternal sabbath of which they are the pledge and the preparation." How startled and confused we should be to hear a literal rendering of our opinion in reference to God's command as given by our acts! Do not the actions of even Christian people often say, *remember*, unless it interferes with your personal plans and pleasures, or makes you different from those about you? Never, until the rest day is kept holy, can the power of dollars and cents (now ruling with sovereign sway) be broken. Never, until then, can the thoughts, aspirations, and *politics* of the land be lifted above the mere greed of gain. Eternal vigilance is the price of every thing that is valuable. True, there are bands of earnest men and women engaged in a hand-to-hand fight upon the question of sabbath or no sabbath; but mostly it is personal work or influence that accomplishes desired results.

But we must set the key-note of our observance *very* high. Especially those high in position and influence should do so, as they are a target for criticism, and may be obliged to decide against certain specific things which their own consciences would ordinarily permit *them* to do, but which they could not do on account of their position.

I have tried seriously to bring these subjects before you, touching upon points for your further thought, instead of trying to amuse you for the time, as I hope it is not with you as has been said of multitudes in the cities, that they need a new set of beatitudes, reading, "Blessed is the man that has money and fun," instead of "Blessed are the pure in heart, for they shall see God." Or, "Blessed is the man that has a job, because he can go to a show," instead of "Blessed are they that hunger and thirst after righteousness," or, "Blessed is the man that has fifty cents, for he can get a dish of ice-cream for his girl and himself."

During the past year California has been the banner State in *work* along the lines of sabbath observance; but it is yet far from being the banner State in general sabbath observance, though some years ago a San Francisco pastor said he had seen the best sabbath observance among the Christian people of California, and some of the characteristics were reverence tempered with love, joyousness, and rare fidelity in Christian service.

The victories or defeats of this cause in one place affect all others. What a widespread stream of death and destruction we sent out from Chicago in 1893! Therefore it is supremely selfish in us to test this question, as we often do, as to what *we* may do by asking, "Will it do *me* any harm?" Every question about sabbath observance should be measured, not by its effects on *me* but on *man*, for whom, in his world-wide home, the sabbath was made. To Christ, the *soul* is the man; but what is man to us? Is it fine clothes, cultured speech, or fine horses? Or, as one has said, is man a "stomach with appendages," as seems to be the idea of those who note Christ's words in disapproval for Sunday feasting and picnics. On five different occasions Christ indorsed the sabbath as of perpetual and universal obligation; but many, who dimly perceive that he antagonized *some* sabbath, have jumped to the conclusion that it was the original sabbath he condemned when it was only the human counterfeit. The Pharisees had buried the restful soul-refreshing sabbath of Eden and Sinai under the rubbish of petty rules, such as, not to walk on grass, as the bruising of it would be a kind of thrashing, nor catch a flea, as that would be a kind of hunting. No woman could wear an ornament, because it would be bearing a burden, nor wear false teeth for the same reason. Some of us nowadays consider the wearing of the latter a discipline along the line of patience and perseverance. A radish could be dipped in salt, but not left there, as that would be making pickle; an egg laid in the way of regular business could not be eaten on that day; but if the hen was kept for fattening, and not for laying, it might be eaten, and so on through hundreds of pages of solemn trifling. It was these Pharisaic additions that Christ pushed away without reverence, and not the divine original or a Mosaic rite or institution.

A letter from Toledo, speaking of a young man who stepped from the cars to a saloon, and stayed half a

minute too long last Sunday night, says, "The saloons make scarcely a *proletense* of closing Sundays, but, in fact, are open *every* day and *all* night!"

This is one of the greatest foes to sabbath observance. It is difficult to consider one without touching the other, as sabbath observance and temperance go hand in hand.

These subjects vast, their weal or woe  
Portend the nation's growth or overthrow;  
And I myself, so weak, can only feel  
Its danger, and my helplessness to heal.

We have the testimony of many of our best men upon this question. Justice Strong says, "He is no friend to the good order and welfare of society who would break down our Sunday laws or set an example of disobedience to them." D. L. Moody says, "Show me the nation that has given up the sabbath and I will show you a nation that has got the seeds of decay." Daniel Webster said, "The longer I live, the more highly do I estimate the importance of a proper observance of the Christian sabbath." Henry Ward Beecher, "An abiding civilization has always gone with the Christian sabbath; and I believe it always will." Bishop Cheney, "If ever this country shall be the sport of revolution, the calamity will be seen to have entered through the rents of sabbath desecration."

Brother, sister, will you not each build over against your own house this wall of salvation to our nation, a holy rest day? Do not ape Naaman's indignation at this apparently small work, and refuse to dip in Jordan while you are looking for some large field of labor. I beg of you to see to it that upon the walls of the secret chamber of your soul are written by the Spirit's power, "Holiness to the Lord;" then you will be careful that no careless action or selfish pleasure dim the reflection of its light upon the world around you.

In closing, permit me to use Paul's words to the Philippians: "Finally, brethren, whatsoever things are true; whatsoever things are honest; whatsoever things are just; whatsoever things are pure; whatsoever things are lovely; whatsoever things are of good report, if there be any virtue, and if there be any praise, think on these things."

MRS. CARRIE BEACH.  
Chatham Center, Medina Co., Ohio.

I wish to call attention to the second paragraph in the above. People are flocking to the United States from all parts of the world, and we rejoice to have them come, providing they will fall in line with our laws and customs, and *especially* recognize that our nation was founded on righteousness. The motto on our coin is, "In God we trust." But when foreigners come over here to enjoy the benefits of our free institutions, and commence straightway to trample down the sabbath, and try in every way they know how to cast ridicule upon Christianity, then these people should be taught *both* law and gospel. During the past season I have visited more pleasure-resorts than for many years, and I have told you something about them; and I have been very much afraid indeed that our people—and especially our young people—were in danger of forgetting the spirit of the beatitudes. I have been very much afraid, as our good friend has expressed it, that money and fun were being more thought of than being pure in heart; and those who are begging for positions for something to do are often the very first ones to flock to the circuses, even though they have lacked for money to buy flour only a few days before.

While it is right that we should enjoy the outdoor air, the companionship of friends, and possibly ice-cream and lemonade, please let us beware how we get down to that low level of spirituality where, instead of hungering and thirsting after *righteousness*, our hunger-

ing and thirsting shall be for a half-dollar and the ice-cream that it may purchase.

Again, we must hold fast to the Christian sabbath, even when it costs us money to do so.\* A few days ago I wanted to cross the State of Ohio. It was going to cost me eight or ten dollars. When I inquired of our agent, "Do you know of any excursion that is likely to come off very soon in that direction?" he said:

"Oh! yes, Mr. Root, there will be one next Sunday, and you can go right down there and back for four dollars."

I shook my head, and reminded him that I did not believe in Sunday excursions.

"Why, Mr. Root, Sunday excursions are getting to be nowadays a most common thing. All the railroads give special low rates on Sunday."

I can not remember what else he said; but when it occurred to me that it was going to cost me something like a five-dollar bill to remember the sabbath day to keep it holy, I breathed a sigh. My friend may have thought it was because I felt bad about losing the five dollars. Bless your heart, no. I never yet lost money in all my Christian life—that is, lost it in the end—by obeying God's law to the best of my judgment, and I had no fear I should lose in this case. But I *did* feel sad and discouraged when I thought of the many Christians who are working perhaps for small pay, whose devotion to and love for the Master's cause is not quite equal to the cross of paying five dollars more for the privilege of traveling on a week day than it would cost them for going on Sunday. Once more, let me add emphasis to that remark of Bishop Cheney: "If ever this country shall be the sport of revolution, the calamity will be seen to have entered through the rents of sabbath desecration."

#### SCABBY POTATOES, AND HOW TO GET RID OF THE INFECTION WHEN IT GETS INTO YOUR GROUND.

This subject has been gone over a good deal, I know, and we have been told again and again how to kill the scab in our seed potatoes with corrosive sublimate. But suppose the scab is already in your ground—what then? Well, my impression has been, after reading every thing I could find on the subject, that there is no very reliable remedy known. The *Rural New-Yorker* suggested the application of sulphur. But I put a barrel of sulphur on about two acres of ground, and

\* Please bear in mind, dear friends, that a religion that costs us nothing, no self-sacrifice or hardship, is good for nothing comparatively. Jesus said, "He that taketh not his cross and followeth after me, is not worthy of me." So do not be troubled or worried even if it does cost you *hard money* right out to remember the sabbath day to keep it holy.

a *part*\* of this "medicated" two acres produced the scabbiest potatoes I ever saw. This year this part did the same thing again. And another piece, where I plowed under crimson clover, produced about 20 bushels of White Bliss potatoes, and not more than two bushels of the whole lot were fit to be called "firsts," on account of the scab. I began to think I should have to give up raising potatoes—at least on certain portions of my ground. Some years ago T. B. Terry spoiled a piece of his ground—at least he spoiled it for potatoes—by giving it a heavy dressing of cow manure. He sorted out all of his scabby potatoes, and fed them to the cows the year before; and then he had scabby potatoes, and no mistake, where *that* cow manure was applied. A few days ago I asked him if he had got that piece of ground "cured." He said the way he cured it was by not trying potatoes there since. That was several years ago. Must I give up potato-growing just because my ground is so exceedingly rich with stable manure? So far I have given you the dark side of the matter. Now for some daylight.

Whenever I plant potatoes after strawberries I get rid of the scab. Is it because we have planted them so late, or because of a heavy growth of foliage on the strawberry-plants? Just at this crisis I got hold of the *Ohio Farmer* for Oct. 14. The very first page of that paper was worth a dollar to me. Here is what I found and devoured so greedily, from the pen of our good friend Alva Agee:

It is the rule, however, rather than the exception, that our scientific authorities in agriculture can help us plain farmers to get at the needed facts, no matter what the local conditions may be. I think that I have a fair illustration of this in one field to-day. Within the last five years two green manural crops have been plowed under in this field, and two matured crops of cow-peas. The soil is in much better mechanical condition, and more fertile. But the agricultural chemists say that a green crop, plowed under in warm weather, makes a soil acid, and I find what is, perhaps, proof of a little too much acidity now, by the presence of a sprinkling of sorrel over most the field in the young clover. The soil is in productive condition, and there has never been sorrel to a noticeable extent in this field; but there it is now, and fairly attributable, probably, to the treatment the field has received.

I have another proof that this late plowing-under of rye, or other green stuff, makes the soil acid. We know that potato scab does not thrive in an acid soil. It spreads where stable manure or lime is used. I have a two-acre lot near the barn that was heavily manured in the past, and has probably grown eight potato crops in the last twelve years. Wheat has too soft straw on it, and clover gets killed under the down wheat; so potatoes seemed a necessity. Three years ago the scab had finally become so bad in the soil that the field was unfit for the crop.

A friend recommended plowing under rye to kill the scab germs in the soil, and the result was a fairly clean crop of tubers. Rye was again sown the next fall, and plowed under a little late in the spring. The crop showed that the soil was being cleansed of this disease; and Director Flagg, of the Rhode Island station, says that such results are likely due to the acid condition of the soil produced by the rye. I do not say that a green crop, plowed under late, will always kill scab, as such a crop does not always increase sourness of land perceptibly; but I do believe

\*The other part, where the sulphur was applied, gave potatoes comparatively free from scab. The next year my crop of chess was on this same ground; and the potatoes were, as I state further along, free from scab. But this, as you will observe, does not score any thing positively in favor of the sulphur application.

that we shall find such means the most effectual one for fighting this disease when it is fixed in the soil. The disease is widespread, and I noticed in the Pittsburg market this season that many shipments were almost unmarketable on account of it. Some souring of the soil is the rational remedy, and this can be secured by the use of ryegrass without seriously diminishing the yield of the potatoes; and in my own case I am sure that the ryegrass always increases the crop of potatoes very materially, being the best fertilizer one can get in a winter-catch crop.

Do you see the point, friends? Now turn to page 502 of GLEANINGS for July last, and see what I said about my winter oats that turned to chaff (?). I told you in conclusion that the chaff was promptly plowed under while in full bloom, June 18, and the ground planted to Freeman and Thoroughbred potatoes. I do not know just when those potatoes were put in, but I think it was toward the last week in June. Had it not been for our severe fall drouth I should have had a good yield of potatoes—yes, a *big* yield. As it was, I had a fair yield for the season; and the happiest part of it is, there was scarcely a scabby potato. In fact, the Freemans were just as nice as Terry's, and some of them weighed a pound.

Now, my understanding of the matter is that planting late has very much to do with avoiding scab. But if we plant late we should turn under some sort of green crop. Now, then, has anybody succeeded in avoiding scab by turning under a green crop *early*? But, by the way, you can not get any green crop to turn under, *very* early—that is, no rank green crop. We turned under some crimson clover rather early last spring; but, as I have told you, that did not help the scab at all.

The next point is, can we avoid the scab by planting about the first of July, or later, even if we do *not* turn under any green crop? Suppose you try extra early potatoes, and dig them and sell them the first of July. If you plant more potatoes on the same ground, will the last ones be freer from scab, when the first ones are badly scabby? I have a partial answer to this question from a neighbor. He planted half of a field to Early Ohio, very early; but something hindered, and it was very late before he put in the rest. The first planted were so scabby that they were hardly worth digging. The last (same seed, same ground, no difference except in time of planting) were the finest potatoes he ever grew—in fact, he took them to the fair, and secured the first premium. In this case the time of planting seems to be the only reason for difference. I do not know whether the weeds got up so high he plowed them under at the second planting or not.

Just one thing more: Can't some of our fertilizer-men give us a fertilizer that will make the ground "sour," so as to kill the scab fungus? I should be glad to get the experience of others on this same point.

#### HOW TO SUPPORT A FAMILY ON A QUARTER OF AN ACRE.

I propose to give you a brief outline of my experience with glass and cold-frames, as my perseverance, after failures, is partly due to my reading "High-pressure Gardening on One-fourth Acre" in your "Tomato Culture."

I commenced four years ago with 14 sash, five miles in the country; raised plants for my own use, and sold

six or eight sash of lettuce and radishes, with a determination to get closer to market. Second year, 35 sash, one acre bottom land inside of corporation of town of 8000 inhabitants: cash rent of land \$275. I made enough to pay rent and expenses; failed to make more, by planting wrong kind of vegetables on high-priced land. Third year, 135 sash, same land and rent; did well in winter, and good prospects for the summer, but was flooded by high water in the middle of May, and again Sept. 1: back-water 5 ft. deep each time, and covered every thing with mud. Result, I made enough before flood to pay rent, and afterward did not make expenses, due to second flood. Fourth year, 235 sash on a lot 80 x 100 ft.; rent nothing, as lot goes with house I live in. Result of sales from this lot, vegetable-plants, \$125; lettuce, radishes, beets, spinach, and parsley, \$600. Sales of celery from July 10th to Oct. 15th, \$80. Celery on hand at present, 12,000 plants—which I am retailing from 60 cts. to \$1.20 per dozen plants—fully two-thirds of it bringing 90 cts. per dozen plants, which makes my lot of less than one-fourth acre run between \$1500 and \$2000, which demonstrates that a family can live on one-fourth acre.

Nov. 1 will enter my fifth year in gardening with 335 sash; and as I empty each bed of celery (the celery is right in the cold-frame) I fill it with lettuce. This is my first year with celery, as I have mostly raised lettuce.

The first year I planted 6 sash of lettuce, and sold most of it. The second year I planted 20 sash of lettuce; sold about two-thirds of it, this market not being used to early lettuce. Third year I planted 60 sash to lettuce; sold all out by April 15th, right when there was the best demand. The fourth year I sold 180 sash of lettuce from December to June. All this lettuce I have retailed in this town, did all the work in garden myself, averaging about five hours each day.

Staunton, Va., Oct. 16.

J. B. LACKEY.

My good friend, I am exceedingly obliged to you for the many practical points you give. First, do not be discouraged if you do not make a success of it at once. Second, beware of localities subject to overflow. Third, have a home of your own, and do your farming in your own dooryard instead of renting high-priced land. Fourth, it pays to be as close to your customers as you can get, even though the ground is high-priced. Your last record is equal to almost any thing I have seen. It seems to me you paid a pretty big price for rent; but circumstances might, of course, warrant such an outlay. But the worst part of it is, you would have to put on fertilizers, and do work that almost doubles the value of the land, for which you would get nothing. Have a piece of ground of your own as soon as you can; and then not only make every foot of it grow something, but *every square inch*.

#### A SUGGESTION IN REGARD TO SETTING STRAW-BERRY-PLANTS.

*Mr. A. I. Root*—I am very little of a farmer or bee-keeper—am simply an old surveyor and civil engineer, who, being too old for active work, has settled down in the country, like a stick of drift-wood, long carried and tossed on the flood, lodging at last on the bank, where it quietly rests until the dust returns to the earth as it was, and the spirit returns to God who gave it.

I have been a subscriber to GLEANINGS for many years, not so much for the bee-keeping news it contains (I read and am instructed in all) as for the general spirit which pervades it and which harmonizes with my own feelings; and it often makes me long for a good quiet talk with you. We both hate humbugs, and the world is full of deceit, sham, and adulterations. The mass of the people like to be deceived, and honor those most who can and will deceive them, because the mass of the people love deceit; they "love darkness rather than light."

As a rule, the part of GLEANINGS I like best begins with Notes of Travel and ends with High-pressure Gardening. I like to look over your price lists, for they give an idea of what things ought to cost. Here,

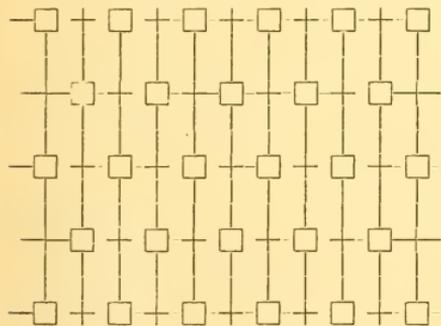

merchants generally charge "all the traffic will bear." On many seeds I can buy in pound lots from you, pay postage, and have the seeds delivered at my postoffice, from 10 to 25 per cent cheaper than I can buy in seed-stores in Portland, Oregon, in 10 and 50 pound lots. They simply scoop the seeds out of a sack or bin, and weigh them out to me, and yet some advertise that they get their seeds in carload lots. In 100-lb. lots they need to charge just a *little* less than they could be obtained from you by freight in 100-pound lots. I am glad to say prices are coming nearer to the eastern level, and I think that you and others like you are to be thanked for it.

I like your High-pressure Gardening very much, and get many ideas and much encouragement from it. You have such an enthusiastic way of talking about things that it makes one feel like trying it for himself.

In Sept. 15th GLEANINGS, page 681, you tell how to set plants so that the lines joining the plants will form equilateral triangles, and each plant be equally distant from the six others nearest to it. I think I can give a more rapid way of doing this work, that, with care, will give just about as accurate results.

Rows are first to be marked out just as you described, say from east to west. Now, given the distance the plants are to be from each other, to find the distance the east and west rows should be apart. This can be done by multiplying the distance between plants by one-half of the square root of 3, which is 0.866; or, if preferred, multiply by 26 and divide by 30, which is nearer the true distance than you can mark the rows. Now mark off the ground with north and south rows, just half as far apart as the plants are to be from each other. Then set plants in the first east and west row, at *every other cross-mark*. Then do the same with the second row, setting the plants in the cross-marks of the north and south lines that were *skipped* in the first row.

Calling the distance between plants 24 inches,  $24 \times .866$  or  $21\frac{1}{2}$  equals 21 inches nearly. See sketch below.

HOW TO LAY OUT THE GROUND WITH A COMMON MARKER SO AS TO BRING YOUR STRAWBERRY-PLANTS LIKE THE CELLS OF A HONEY-COMB.

This method can be applied to trees as well as plants, on large fields as well as small plots.

I think of trying a half-acre or more of mangels by this method next spring, setting plants 18 inches from each other, as I find they stand transplanting well. Transplanting is much slower work than drilling, but will save much time in weeding and thinning. If plants are set 18 inches apart, there will be a little over 22,000 plants per acre. I have had mangels that weighed over 20 pounds. Now let Huber figure how many tons per acre 20-pound mangels would give, and see if that is not "high-pressure" gardening.

Corbett, Ore., Oct. 5. JOHN A. HURLBURT.

Friend H., we are much obliged to you, and we are very glad to find a civil engineer who is turning his attention to high-pressure gardening. No wonder you gave us so short and accurate a method of arranging plants hexagonally. To do this we really ought to have two markers—one to make marks one foot apart, and the other to make them nearly 21 inches. With a horse, and a marker say six or eight feet wide, ground could be marked very rapidly. For small areas, of course hand

markers made narrower accordingly would be more convenient. I hardly need explain to our readers that the squares are to represent strawberry-plants. Thanks for your kind words for our efforts in the way of cutting off the profits of middlemen, and getting seeds directly from the grower to the planter by the shortest cut. This season our cucumber and melon seeds are all grown especially for our trade by a seed-grower who is also a bee-keeper. If I were to tell you what he gets from seed-growers for his seeds you would not wonder we are able to offer many of them at half the prices made by many of the catalog men.

We copy the following from the *Ohio Farmer* for Oct. 14:

#### A BOLD SWINDLER.

In our news items last week we referred to the arrest of Carl B. Cline at Columbus, O., for using the U. S. mails for swindling purposes. The Columbus papers give us full particulars. At the bank he was known as Cline; at Livingston's seedstore he was known as Mr. Craft. He bought most of his "sample" seed wheat at Livingston's. At his apartments on Naghten St. he was known as "Mr. Ferrington." About Aug. 1st he advertised "Early Surprise" wheat in the agricultural columns of religious papers from Maine to California. He also advertised in some agricultural papers. He said he raised 363 bushels of this wheat from 10 acres; that it had such stiff straw that it could not be blown or beaten down by storms, etc., and offered to send sample by mail for three two-cent stamps. The stamps poured in from all over the country, and he sent samples of wheat purchased at Livingston's, accompanied with a circular offering to ship one bushel for \$1.50, five bushels for \$1.35 a bushel, and ten bushels or upward for \$1.25 a bushel. Orders poured in at the rate of \$50 to \$100 a day; and the officers who arrested him Oct. 1st estimate that he had received fully \$2000. When complaints began to come in he bought some rejected wheat and filled part of the orders, but most of them were not filled at all. His race was short.

Now, friends, where is the trouble? Who is to blame? The trouble is here: This man, when he advertised, was a new man, unknown to anybody. Before sending him money, the farmer should have gone to the bank and had them look the advertiser up; or, if that is not convenient, write to the editor of the paper that published the advertisement, and ask him to find out whether or not the advertiser is responsible. This can be done in a minute's time by anybody who has access to Bradstreet or Dun. If you can not find his name, do not send him any money. Beware especially of anybody who claims to have something greatly superior in a great staple like wheat. Our experiment stations are watching every thing of this sort with great interest. An investigation in Columbus would have brought to light at once the facts given above. And now I hope none of the agricultural papers will feel hurt when I suggest that no advertisement should be received from *anybody* until he gives satisfactory reference, or is found quoted by Dun or Bradstreet. If this were followed up, such fellows as "Cline," "Craft," and "Ferrington" would be brought to a standstill at the outset. They could never get into any agricultural paper, and, in fact, I should like to say in *any other* paper until given some reasonable proof that they were straight square men, and not somebody sailing under an alias or false colors of any sort.

## KIND WORDS FROM OUR CUSTOMERS.

The queen you shipped Sept. 13 came in splendid condition, and I must say I was very well pleased with her—7 days on road. There was not one dead bee in the lot.  
NEWTON SHELDON.  
Big Pine, Cal., Sept. 29.

The sections you sent me have come to hand, and they are the nicest I ever had. They are square when put together, and the dovetailed corners fit nicely. I am surprised at the low freight rates from Medina. I don't think I shall ever try to keep bees without GLEANINGS.  
W. H. PARKER.  
New Castle, Ala., June 29.

Please accept my sincere thanks for your very kind note telling me how best to treat the "Darling" strawberry-plant recently received from your house. It is the very handsomest plant I have ever seen. I did not need to shade or coddle it in the least. When I took it out of the box it was as fresh as when you put it in. It has already made two new leaves and a runner, which last I promptly clipped. My pit is an excellent one, well drained, with a southern exposure, so that I am expecting the plant to start into an early and vigorous growth next spring. This plant is so handsome and well established that I feel sure it must be greatly superior to any thing that you will send out in quantities, nevertheless I shall send you an order for some of your pet Jessies in the spring. By that time I shall have mastered the A B C so thoroughly as to be able to treat them intelligently.  
Richmond, Ky., Oct. 4. MISS MARY F. CROOKE.

## Gleanings at Reduced Rates.

With a view to encouraging membership in all kinds of bee-keepers' associations whatsoever, local or otherwise, we have decided to offer GLEANINGS at 75 cts. per name to members of such organizations. Old or new subscribers may take advantage of this offer; but in the case of the old, all back subscriptions must be paid up before the 75-cent rate for a year will be allowed; otherwise only nine months will be credited.

We must either require all subscriptions at this reduced rate to come through the secretary, or we must have evidence of some sort that you belong to some bee-keepers' society. Simply a line from the secretary, stating that you are a member in regular standing, will suffice. At your next annual meeting, bear this in mind; and if you wish to become a subscriber to this journal, hand 75 cts. to your secretary, and when that amount is received by us your name will be placed on our subscription list for 12 months.

If you do not now belong to any association, send \$1.75 to us or to secretary Dr. A. B. Mason, of the United States Bee-keepers' Union, at Toledo, Station B. This will entitle you to a year's membership and protection in the Union, and one year's subscription to this journal.

**The A. I. Root Company,**

**Geo. J. Nissly, Saline, Mich.**

## WINDOW GLASS ADVANCING.

With returning prosperity throughout the country generally, the prices of many commodities are advancing. Window glass is affected by the advancing market to a much greater degree than most things. The shipping case glass listed in our catalog we can no longer sell at \$2.50 per box of 50 feet; but from now on the price will be \$3.00 a box till further notice. This would necessitate a change in the price of shipping-cases complete with glass if you did not do something else to overcome it. We have discovered that large glass-jobbers accumulate a great many two-inch strips, especially of double-thick glass, and these we are able to buy at a special price. By grooving the glass strips with a wide groove, and the right size to take two-inch glass, we can furnish shipping-cases complete at the regular price. For cases with three-inch glass the price will be 25 cts. per 100 extra on two-row cases, 12 and 16 lb.; 50 cts. per 100 extra on three-row cases, 12-lb.; \$1.00 per 100 extra on 24-lb. cases. The double glass in strips 2x9, 2x13½, 2x17½, 50 feet to the box, we can supply at \$2.00 per box.

## WIRE NETTING.

To reduce present stock of wire netting we offer 2-in. No. 20 and 2-in. No. 19 wire netting from Medina at the following special prices for the various widths: 12 in. wide, No. 20, \$ .60 a roll; No. 19, \$ .65 a roll.

|    |   |   |      |   |   |      |   |
|----|---|---|------|---|---|------|---|
| 18 | " | " | 90   | " | " | 1.00 | " |
| 24 | " | " | 1.20 | " | " | 1.30 | " |
| 30 | " | " | 1.50 | " | " | 1.65 | " |
| 36 | " | " | 1.80 | " | " | 2.00 | " |
| 48 | " | " | 2.40 | " | " | 2.60 | " |
| 60 | " | " | 3.00 | " | " | 3.30 | " |
| 72 | " | " | 3.60 | " | " | 4.00 | " |

Each roll at above price is to be 150 feet long. We have of some of the widths a few rolls that are short length a few feet on each. These we would put in at the same rate while they last. Notice that these prices are a reduction of over ten per cent from former rates, and are made only on orders filled from Medina stock while it lasts. The same discounts for quantity will apply; namely, 5 per cent for five rolls, or 10 per cent for 10 rolls or more. We have some 150 rolls in stock of all widths, both sizes. Send on your orders, as these prices can not last long, and are lower than you can buy the same goods for elsewhere.

## HONEY MARKET.

Having had numerous calls for extracted honey in glass jars we have decided to supply it in this form. We have chosen the square flint jars, which, with label on top and neck of jars, form a very attractive as well as convenient package. These are put up in small boxes with corrugated-paper packing to secure safe carriage. We are using the California white sage for this trade, as it does not candy; we offer it as follows: One-pound jar, one dozen in a case, per case, \$1.80; half-pound jar, two dozen in a case, per case, \$2.40; five-ounce jar, two dozen in a case, per case, \$1.70. We also can supply this honey in 60-pound cans, 2 cans in a case, at 6½ cts. per lb. Lots of five cases at 6 cts. per lb. Clover and basswood in cans at same prices, when we have it.

We also have on hand comb honey which we offer in lots of 100 lbs. or more as follows: Fancy white, per pound, 13c; A No. 1 white, 12c; No. 2 white, 11c; fancy amber, 11c; A No. 1 amber, 10c; No. 2 amber, 9c; fancy buckwheat, 10c; A No. 1 buckwheat, 9c. Lots of 500 lbs. shipped direct from producer at 1c per pound less.

## Special Notices in the Line of Gardening, etc.

By A. I. Root.

## RELIGIOUS PAPERS AND BOGUS ADVERTISEMENTS.

On page 789 we are told that the new wheat was advertised principally in religious papers. What does this mean? I am afraid it means swindlers have discovered religious papers are a better field for swin-

dles than agricultural papers or papers of any other sort. In one sense this is a compliment to Christian periodicals; but if this thing keeps on—if religious papers do not soon learn that it behooves them to take as great care to keep out frauds as agricultural papers do, the great world at large will begin to lose faith in the very papers that should above all others teach honesty and truth even in their advertising columns. Permit me to say here I have been greatly rejoiced to find the *Golden Rule* has not contained an advertisement of Electropoise for several months. If this is to continue, I can honestly recommend the exponent of the Endeavor Society as one of the best papers in the whole wide world to put into the family.

## PRICES OF SEED POTATOES.

I have been carefully scanning our agricultural papers, especially the advertising columns, and I find only one man who advertises seed potatoes for less than we do, and this is only a little less. He offers Sir Williams for 90 cts. a bushel, while our price is \$1.00 in barrel lots, however, our price is a little less than 90 cts. Notwithstanding, to be consistent we will sell a single bushel, and furnish sack to hold them, for 90 cts.; and if you hesitate about sending your orders to me because some reliable man offers the same potatoes cheaper, please let me see his advertisement and I will try to duplicate his prices. I do not want to undersell my neighbors in the same business, neither do I want my prices to be higher than theirs. Please bear in mind that my potatoes have been grown under my own personal care, and the greater part of them have been dug and picked up and assorted under my personal supervision. For immediate orders we can furnish you some of the finest State of Maine potatoes I ever saw, for 65 cts. per bushel, including sack to ship them in. If to go long distances, and you order three or more bushels, we will put them in a barrel at the same price.

## THE BOVEE EARLY POTATO.

We have toward 50 bushels of very handsome potatoes of this new extra-early variety. At the present writing we can make the following prices: 1 lb., 30 cts.; 3 lbs., 75 cts., when sent by mail; if sent by freight or express, ½ peck, 50 cts; peck, 80 cts.; half bushel, \$1.50; bushel, \$2.25; barrel of 11 pecks, \$5.00.

In regard to this potato, our Ohio Experiment Station last year reported a yield of over 500 bushels per acre, and it was tried with the Early Haver; Nother, Thorougbred, Early Ohio, and Rose, and went far ahead of any of them. We have not as yet received a report from it this year, but here is what they said about it last year:

"It seems to be quite as early as Early Ohio, and there is no doubt about its being more prolific. We regard it as very promising, and we think we have had a chance to test it quite thoroughly, as we had three plantings. It has uniformly given good results, hence we confidently recommend it."

Just as we go to press we find the following in a letter from Prof. W. J. Green:

The Ohio Agricultural Experiment Station.

Wooster, Ohio, Oct. 25, 1897.

Dear Sir:—Our late-planted crop of Bovee potatoes has turned out well, and the tubers are smooth.

Yours truly, W. J. GREEN.

Permit me to add that we have purchased the crop grown by the Experiment Station.

Here is also something just at hand from C. N. Flansburgh, Leslie, Mich.:

The general yield in this section is light; but we shall have nearly 200 bushels of the Bovee from one barrel of seed.

Yours very truly, C. N. FLANSBURGH.

Perhaps you may know that Peter Henderson gave it a big boom during the past season. We made a test of it on our own grounds, but did not get it planted at the time of our other extra-early potatoes, so we could not give it a fair comparative test. If anybody else offers it at a less price than that given above we will try to make ours correspond.

## WINTER CASES FOR PENNSYLVANIA!

Root's goods at Root's prices. Send for catalogue.

PROTHERO &amp; ARNOLD, Dubois, Pa.

FOR SALE.—Green-bone cutter. Good order; can be used with power; bargain.

Box 57, Medina, Ohio.

## KIND WORDS FROM OUR CUSTOMERS.

The Ajax wheel came Monday, the 11th, all right. It is a fine-looking wheel. F. H. SACKETT.  
Piccolo, O., Oct. 13.

I send you \$1.00, and will send more soon; but don't stop that paper, as I can not do without it. I have been in a tight row financially, but must have GLEANINGS. It is the best religious and agricultural paper that comes. Put on the white-rose button, Bro. Root, Newark, O. H. HOLLER.

### STRAWBERRIES AND RASPBERRIES—SECOND CROP.

We have picked a second crop of strawberries on old beds for two months, and the last month has been very dry. We are also picking quite a second crop of Cuthbert raspberries. Nearly every plant has a bunch of blossoms and berries. This is the first time I ever heard of Cuthbert bearing a fall crop.  
Claremont, Va., Oct. 11. A. F. AMES.

### QUEEN TO AUSTRALIA.

I have received the two Carniolan queens—one dead and one alive. The cage with live queen contained two live workers only, and all the honey had been consumed, and about half the candy. In the other cage a little honey still remained, and about three-fourths of the candy. Bees are doing well.  
Godna, Queensland. H. L. JONES.

[It would seem from this that honey was the important part of the food. There can be no doubt of its value in queen-cages designed for long distances.—Ed.]

### CLEATED SEPARATORS AND NO-BEE-WAY SECTIONS WANTED.

If you have not shipped goods ordered on the 13th inst., please send the cleated separators and the "no-bee-way sections" for the Danzy hive, if you have them. If not in stock, ship the rest of the order and I will wait till you have some of these. I have just read the editorial on page 744, and it is the same idea I have had for some time. In fact, I made and used a few last year that pleased me wonderfully. I also tried holes in the separators, which was an advantage.  
Bristol, Tenn. M. D. ANDES.

### OUR TRANSPLANTING-MACHINE.—SEE PAGE 462.

The strawberry-transplanting machine I bought of you a few weeks ago is an exceedingly useful tool, almost invaluable. I have used it to set out a thousand plants. I planted some potted plants at the same time, and, so far as I can see now, those moved by the transplanters are doing just as well as the others. It is also a great help in setting out potted plants. I stretch my line, put marks on it just the distance apart I want to plant, walk along, make holes with the planter, and some one follows and drops the plants in, fills with a little earth mixed with bonemeal, and the job is done to perfection. As I can irrigate my patch by simply turning water on it from a creek higher up, I have been able to plant right in the midst of this severe drouth.  
Asheville, N. C., Oct. 7. C. E. MOODY.

### AN EXCEEDINGLY "KIND WORD" AND A BRIGHT MORAL, BESIDES.

A few days ago I found the following on my desk: \*  
Mr. A. I. Root.—Is it too late to sow spinach in this latitude? If not, I should like you to send me enough seed (spinach) to drill in one acre. Please state distance apart drills should be, and care and culture necessary for growth of this crop (very briefly). I have a Planet Jr. drill bought of you. I will remit for seed when received. Do not send it too late to sow. The land I think of sowing has been cultivated sixteen times this season. No frost here to date.  
Hickman, Ky., Oct. 18. D. W. DICKINSON.

We promptly sent our friend 10 lbs. of seed, with the following directions:

It would be a little late in our locality for sowing spinach, but we should think it would be about right where you live. The main thing is to have the ground real rich. You do not say how much it has been manured. On the whole we have concluded to send the seed along. The extra cultivation is just the thing. If it does not get large enough before freezing weather it will come up all right next spring—that is, if

your ground is underdrained or has sufficient sand or gravel so the plants will not heave out. One ounce should make about 1.50 feet of drill, and I would have the rows about a foot apart. If you wish to cultivate with a horse it should be between two and two and a half feet. Ten pounds will be plenty of seed, and this is the amount we send you. You do not tell us how to seed it; but as it will go almost as cheap by express, and much quicker, we send it in that way to Hickman, Ky. Spinach does very well sown at the same time you sow wheat; and I think very likely they are sowing wheat in your locality now, Oct. 20, as we sowed some last week.

Of course, I supposed that would end the matter; but imagine my surprise when I received the following:

Dear Friend and Bro. in Christ.—The longer I know you, the more I find in you to admire and esteem; and I do believe you are the "one in ten thousand." May God ever bless and prosper you is the prayer of the writer.

Some days ago I sent you an order for spinach seed. I knew nothing about the cost of seed or cultivation; in fact, I was utterly ignorant about the plant. Well, after the letter was mailed I began to think, "I've done a reckless thing. I don't know whether the seed costs 5 cts. per lb. or \$5.00;" and then I consoled myself by the thought, "A. I. R. is sure to do the right thing." I received the bill Saturday, and was astonished at the paltry price, 10 cts. per lb., and 25 cts. to my credit.  
D. W. DICKINSON.

Hickman, Ky., Oct. 25.

The "bright moral" I gather from this simple transaction is this: This world is not a bad one to live in after all. It is not a very hard task to please the average of humanity; and the most important thing is to conduct all your business having in view first and foremost helping humanity along. Do not let self or selfish interests warp or twist your judgment. In the first place, our friend seems to have forgotten that we placed to his credit \$1.25 in a potato deal last spring. If I am correct, he sent his money in accordance with our printed prices; but before the order reached us there had been a decline. Again, when he stated his wishes in regard to the spinach (something he had never bought), without thinking any thing about it I advised only a moderate investment in the seed, etc. There are good nice kind people in this world; and when you are tempted to think otherwise, remember it is Satan himself who has gotten hold of you.

## Two Bee Papers for the Price of One.

To all new subscribers, and also to those who renew before their subscriptions expire, and inclose \$1.00, we will send the *Busy Bee*, a monthly bee-paper, in addition, free.

THE A. I. ROOT CO., Medina, O.

## Wants and Exchange Department.

WHAT will you offer for one b-flat cornet and case, also one e-flat alto, good instruments, practically new? Address Box 321, Clifton, New York.

WANTED.—To exchange 1 "Planet Jr." double-wheel hoe complete, used only couple of times, for a good coon dog. I. S. TILT, Box 73, Filion, Mich.

WANTED.—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules.  
ANTHONY OPP, Helena, Ark.

WANTED.—To exchange 65 volumes Scientific American, volumes 1, 2, 7, 8, 9, 15 to 33 inclusive, 36 to 77 inclusive, unbound, good condition, for bicycle, view camera, firearms, or offers.  
J. E. HAMMOND, Oxford, Mass.

WANTED.—For exchange, tandem and single bicycles, Marlin repeating rifle, 32 caliber. Wanted, Barnes saw.  
ROBERT B. GEDYE, La Salle, Ill.

## Two Papers for the Price of One.

The **Farm Journal**, of Philadelphia, a monthly agricultural journal of 16 pages, sent **One Year Free** for one subscription to **Gleanings**, with \$1.00, paid in advance, either new or renewal. In the case of a renewal, all arrears, if any, must be paid in addition to one year in advance.

The **Farm Journal** is now in its 20th volume, and takes the lead among all the *low-priced* agricultural journals of this country and of the world. It gives no chromos, puffs no swindlers, inserts no humbug advertisements, lets other folks praise it, and makes good to subscribers any loss by advertisers who prove to be swindlers. The editor was born on a farm and reared at the plow-handles, and the contributors are practical men and women.

The regular price of this excellent journal is 50 cents a year, and it is well worth it; but by special contract with the **Farm Journal** we are enabled to make the above very liberal offers.

THE A. I. ROOT CO., Medina, Ohio.

## A Bargain!

Only \$1.50. We have made arrangements to furnish **THE OHIO FARMER**, of Cleveland, Ohio, and **GLEANINGS IN BEE CULTURE**, both papers, for only \$1.50.

The **Ohio Farmer** is well known as one of the very best, largest, and among the leading agricultural papers of America. A 20-page, 80-column paper EVERY WEEK in the year; employs THE VERY BEST WRITERS that money can procure; a strong, fearless defender of the agricultural interests of this country, and CLEAN in both reading and advertising columns. IT HELPS MAKE THE FARM PAY.

THE A. I. ROOT CO., Medina, Ohio.

## Gleanings in Bee Culture AND American Agriculturist.

Weekly.

**BOTH ONE YEAR ONLY \$1.25.**

By special arrangement with the publishers, we are enabled to offer the **American Agriculturist** in combination with **GLEANINGS IN BEE CULTURE** at the unparalleled low rate of \$1.25 for both papers one year. The **American Agriculturist** is published in five editions. The N. E. Homestead, the Eastern, Middle, and Southern editions of **American Agriculturist**, and the **Orange Judd Farmer**. Each contains matter relating to its own locality, as well as the latest and most accurate market reports for the country in general. It has departments relating to all branches of farming, articles written by the most practical and successful farmers, supplemented with illustrations by able artists. Short stories, fashions, fancy work, cooking, young folks' page, etc., combine to make a magazine of as much value as most of the special family papers.

A sample copy will be mailed FREE by addressing AMERICAN AGRICULTURIST, Columbus, O., or New York, N. Y.

TAKEN separately these two papers cost \$2.00, consequently every subscriber under this offer will get

**\$2.00 IN VALUE FOR \$1.25.**

**Premium Books.** For 10 cents extra, as postage, you can have your choice of any of the following standard books FREE: "Profits in Poultry," "Farm Appliances," or "Farmer's Almanac" (ready December 15). Send your subscriptions direct to

THE A. I. ROOT CO., Medina, Ohio.

---

## PREMIUM LIST.

---

### Valuable Inducements to Secure Subscriptions to GLEANINGS IN BEE CULTURE.

---

New Subscriptions for 1898 Received Before the End of This Year will Receive the Remaining Issues of This Year Free.

---

## Premium Rules.

Please Read These Rules Carefully and Thus Avoid Misunderstandings.

We believe most of the readers of GLEANINGS appreciate it enough to continue with us without the extra inducement of premiums. These are offered with a view of increasing our number of readers by the addition of new subscribers. The premiums are intended for those who, by personal effort, secure the subscribers. These persons are almost always those who already read GLEANINGS, and know what it is. We are glad, therefore, to pay you well for your trouble. *No premiums will be given to news-dealers or subscription agents.* 1. Both renewals and new names count toward securing premiums. A transfer of subscription from one member of a family to another is not a new name, as it does not make any addition to our list. Note also exceptions under different premiums.

2. No name will be counted for premiums unless it is accompanied by \$1.00; and in case of renewals all arrearages, if any, must be paid up, and \$1.00 sent for a year in advance—the advance subscription only, counting for a premium. Remember that you can not claim more than one premium on each subscription. This rule applies to all premiums offered in other issues besides this premium list. Inclose postage if premium is ordered by mail.

3. You can close your list of names at any time, and call for the premiums due; or you can add to the list of names. But—

4. Send along the names as fast as gathered, so that the subscribers may begin to receive the jour-

nal at once. No subscription should be taken for less than \$1.00 per annum.

5. Mark every name or list of names, "For Premiums," if so intended, and we will credit them to the sender on our premium-record.

5. Be sure to give the Name, Postoffice, County, and State of each subscriber and of yourself.

6. All sample copies necessary to canvassers will be sent postpaid free.

7. When you order your premiums be sure to state HOW TO SEND, and if by mail do not forget to include postage named under each article in addition to the amount named as covering the article and a year's subscription.

8. To Foreign Readers. To all foreign countries, 48 cents must accompany subscription, for postage.

9. How to Send Money.—1. Tell how much you inclose and of what it consists. 2. Money may be sent without risk of loss in three ways:

By bank draft on any responsible city bank.

By express money order on any express company. By postoffice money order.

If you send by any of the above methods, and your order should be lost, you can get a duplicate.

If there is no bank, express office, or money-order office near you, so that you can not use any of the above methods, you may send by registered letter, and we will be responsible; but if any of the methods first named are available, we will not be responsible for money sent in any other way. Do not send coin in letters; if you do, they are at your risk.

---

## PREMIUMS IN CASH.

### LIBERAL COMMISSIONS TO WIDE-AWAKE WORKERS.

---

Notwithstanding the very liberal offers we make in premiums in the following pages, there may be some who prefer a cash commission to any of the premiums offered. As we are desirous of increasing our list of subscribers to double the present number, if possible, we propose offering the following large cash commissions:

For one new subscription, sent with your own renewal, you may retain 35 cents, sending us \$1.65. For three new subscriptions, with \$3.00, you may have your own subscription advanced one year. For each additional new subscription you send you may retain 40 cents.

For each additional renewal which you obtain and

send with yours, you may retain 20 cents provided all arrears, if any, on such subscriptions are paid in full, and the payment for a full year in advance is the only part from which you retain your commission. This will not apply to a person sending in his own renewal. Nor can you claim any other premium if you choose the cash commission.

If you wish to subscribe for more than one year in advance you may do so at the following rates:

One year, \$1.00; two years, \$1.75; three years, \$2.50; four years, \$3.00; five years, \$3.50; 10 years, \$6.00. In any case the name would count as one renewal in obtaining a premium.

## A B C of Bee Culture.

It is hardly necessary to speak of the merits of this work, which, judged from its extensive sale, is the most widely read book on bee culture in the English language, and, for aught we know, in any language. The last edition completed 62,000 copies from the press during the last eighteen years since it was first printed. This last edition has been greatly improved. It is enlarged to 475 octavo pages, with over 300 illustrations, many of them full-page. Some of the latter embrace a view of the apiaries of some of the largest and most successful bee-men. In the back part of the work is a biographical department of sketches and half-tone portraits of the most successful American apiarists. The whole work is brimful of contagious enthusiasm, and the style simple and instructive. None of the matter pertaining to the apicultural part of the book is electrolyped, but all is kept in standing type, so that when any new thing of importance comes up it can be inserted in its proper place, and the old struck out. Its quick sales have warranted us in giving it frequent and thorough revisions. The present edition is greatly enlarged and improved, so that it is nearly twice the size of the one first issued; and no bee-keeper having one of the earliest copies can afford to be without this latest edition. The book has grown so large that it now takes 19 cents postage to mail it. We have not advanced our prices, however. Price \$1.20 postpaid; \$1.00 with other goods. GLEANINGS one year, clubbed with the A B C, postpaid for \$2. Clubbed, postpaid, with a new subscription for \$1.75. If you send two new subscriptions with your own renewal and \$3.00, you may have the book postpaid; or if you send one new subscriber with your renewal and \$2.50 you can have the book prepaid.

### Our List of 10c Books.

Six of any of the following sent postpaid for one new subscriber and your own renewal with \$2.00, or two sent postpaid for your own renewal with \$1.00.

#### Peabody's Webster's Dictionary.

25,000 words and phrases, and illustrated with 250 engravings; cloth bound. This is the one we sold for years at 15 cents. We thought we had done something wonderful when we offered so large a dictionary for 15 cents, but we are now able to sell them for a dime. Just think of it! Postage extra 5c.

#### Poultry for Pleasure and Profit.

48 pages and 20 illustrations. A complete little book of instructions. It treats of the best varieties for pleasure and profit; how to house and yard; how to manage; how to feed; diseases, incubation, etc. It is a 25-cent book, but by getting 1000 of them we can sell them for 10 cents. Postage 1 cent.

#### The Horse and His Diseases.

By Dr. B. J. Kendall; 100 pages and many illustrations. Over 500,000 of these books have already been sold, because they are so popular and complete, for a small hand-book. It gives the symptoms of most diseases, and treatment for the same. This is another 25-cent book that we got down to a dime by taking 1000 of them. Postage 3 cents.

#### Silk and the Silk-worm.

This is a complete work of instruction on silk culture, by Nellie Lincoln Rossiter, a practical silk-culturist; 32 pages. Silk culture is the favorite pursuit of many ladies in our land; and all who are interested will find this little work very instructive. The price printed on it is 25 cents, but we sell them for 10 cents. Postage 1 cent.

#### New Testament, New Version.

434 pages, printed in nonpareil type. This should be in the possession of every student of the New Testament. Even if it does not come into common use, it is helpful to know what changes in translation the New Version gives. Postage 5 cents.

#### John Ploughman's Talks and Pictures.

By Charles Spurgeon; 125 pages, and a picture on almost every page. John Ploughman talks plainly, and makes a good point in every talk. It is by no means dry reading, either. Postage 3 cents.

#### Life and Adventures of Robinson Crusoe.

240 pages, paper covers. Until now 20 cents. Although they cost us more than 10 cents each, we offer them at that price. Five cents extra by mail. There are few books so universally read as this one, and there are many editions printed. At the price, this one is a bargain.

#### Practical Turkey-raising.

By Fanny Field, the most experienced turkey-raiser in America. This is a regular 25-cent pamphlet of thirty pages, giving the best information on this subject. Our price is only 10 cents. By mail 2 cents extra.

#### Injurious Insects of Michigan.

By Prof. A. J. Cook. This was a most valuable work in its time, but is now rather old. It sold for 25 cents. We will close out the few we have on hand at 10 cents each, postage 2 cents extra, and it is a bargain at this price; contains 48 pages the size of this, and 50 illustrations of insect pests.

#### Silo and Silage.

By A. J. Cook. This is another valuable little book which sold for 25 cents, and which we offer to close out at 10c. Postage 2 cents extra.

#### Guide to Horse-owners,

and complete Horse Doctor. By M. Young. A valuable pamphlet of 100 pages. Regular price 25c. Will close out at 10c each. By mail 2c extra.

#### A Dozen Attractive Pamphlets.

Seven of any of the following postpaid for one new subscriber and your own renewal with \$2.00, or two sent postpaid for your own renewal with \$1.00.

They are not only attractive, but so valuable and helpful that they should be read by every one who desires to improve his life, and live happier; and who does not have such desire? Doubtless many have read "The Greatest Thing in the World; or, Love the Supreme Gift," by Drummond; and others have heard of it. "Love is the fulfilling of the law;" and the more of it we can get into our lives, the better for the world and for us.

These little books are 16mo, 32 pages, with handsome light-blue parchment cover, and nice, clear print. Price 10c each or 90c per dozen, any one or assorted books, postpaid or with other goods. Publisher's price 20 cents each.

1. Love, the Supreme Gift; The Greatest Thing in the World. By Prof. Henry Drummond.
2. The Perfected Life: The Greatest Need of the World. By Prof. Henry Drummond.
3. How to Learn How. Addresses by Prof. Henry Drummond. I. Dealing with Doubt. II. Preparation for Learning.
4. Power from on High: Do We Need It? What is It? Can We Get It? By Rev. B. Fay Mills.
5. The Message of Jesus to Men of Wealth. A Tract for the Times. By Rev. George D. Herron. Introduction by Rev. Josiah Strong, D. D.
6. The First Thing in the World; or, the Primacy of Faith. By Rev. A. J. Gordon, D. D.
7. Hope: The Last Thing in the World. By Rev. A. T. Pierson, D. D.
8. The Fight of Faith and Cost of Character. Talks to Young Men. By Rev. Theodore L. Cuyler, D. D.
9. The Four Men. The Aspect of Man from Four Standpoints. By Rev. James Stalker, D. D.
10. How to become a Christian. Five Simple Talks. By Rev. Lyman Abbott, D. D.
11. The D-w of thy Youth. A message to "Endeavorers." By Rev. J. R. Miller, D. D.
12. Temptation. An Address to Young Men. By Rev. James Stalker, D. D.

**Drummond's Addresses.**

Besides the booklets above we have Prof. Drummond's addresses, six in number, with biographical sketch, making a 16mo book of 140 pages, bound in board covers, part cloth and part paper, in two shades of blue, neatly figured, making a very handsome book. Price only 30c postpaid, or 25c if sent with other goods. Given for your own renewal with \$1.10.

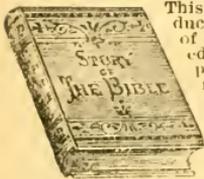

**Illustrated Pilgrim's Progress.**

We have secured some of a very fine English edition of Pilgrim's Progress, illustrated with over a hundred very realistic pictures. The book is 16mo, printed on very fine paper, containing 384 pages, and the illustrations are the most striking, and true to the characters represented, that we have ever seen in the most expensive editions. The binding is cloth, richly illuminated in six colors, with title in rich goldleaf on back and side. There is no paper wasted in wide margins; in fact, there is so little trimming that some of the leaves have to be cut apart. It is a book of such quality and make-up as to easily bring \$1.50 at retail a few years ago. In this day of cheap books and low prices it is necessary to close out the last of the edition away below actual value. We offer these at 50c each; by mail, 10 cts. extra. We will give one free postpaid for one new subscriber with your own renewal and \$2.00, or postpaid for your own renewal with \$1.35.

**Foster's Pilgrim's Progress Illustrated.**

This is from the Charles Foster Publishing Co., Philadelphia, where the Story of the Bible comes from. The book is 9 1/2 inches long, 7 1/4 wide, and 1 1/2 thick. It has 425 pages and 175 illustrations. Ever so many, to whom I have shown it, pronounce it a \$2.00 or a \$2.50 book; but by buying a large number of them at a time we can sell them to you for only 75 cts. This book is so heavy, however, that it can not be sent by mail for less than 23 cents, making 98 cents by mail postpaid. The covers are most beautifully embellished in scarlet and gold, and many of the pictures are worth to me alone the price of the book. Among them I would mention Christian and Pliable in the Slough of Despond; Mr. Worldly Wiseman; Giant Despair, etc. But the sweetest and best of them all to me is Prudence talking to the boys. A single glance at the book by anybody, when you mention the insignificant price for so beautiful a volume, will make him hold up his hands in astonishment. Each 75 cents. Given for one new subscriber and your own renewal with \$2.00, or given for your own renewal with \$1.50. Postage 23 cts. extra. Gilt edge 25 cts. additional.

**The Story of the Bible.**

This wonderful book is the production of Rev. Charles Foster, of Philadelphia, lately deceased. It is the whole Bible reproduced in simple language, making a book of 700 pages, illustrated with 274 engravings. It is so plainly and pleasantly written that grown people, as well as children, will hardly want to lay it down. In the hard passages in the Bible, difficult to understand, it makes a commentary that will be thankfully received by some others besides children. Indeed, it has proven so simple, reliable, and helpful, that it has been reprinted in many foreign languages. Over 400,000 volumes have been sold since it was first issued. It is a well-made book, printed on fine paper. Regular agent's price is \$1.50. Our price is \$1.00; 20 cents extra if sent by mail, or given free for one new subscriber and one renewal with \$2.25, with 20 cents extra to pay postage.

**Bible Pictures, and What They Teach Us.**

By Charles Foster. It contains 315 large illustrations from the Old and New Testaments, with brief descriptions. It contains 232 pages, 8x10, with embossed cloth cover, title in gilt, printed on heavy paper. The book weighs 2 1/2 lbs. It will make an excellent Christmas or birthday present for a child. It is written chiefly to instruct the children, and should be in every home. Regular agent's price, \$1.50. Our price, \$1.00. By mail, 20 cts. extra. Given for two new names and your own renewal with \$3.00, and 20 cts. extra to pay postage, if sent by mail.

**ANY TWO** of the following books given for one new subscriber and your own renewal with \$2.00, or any one given for your own renewal with \$1.10. If by mail, add 5 cents each for postage.

**The A B C of Potato Culture.**

Paper, 220 pages, 4x5, illustrated. This is T. B. Terry's first and most masterly work. The book has had a large sale, and has been reprinted in foreign languages. The second edition, reset and almost entirely rewritten, is just issued. When we are thoroughly conversant with friend Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. Price 40c, postpaid.

**The A B C of Strawberry Culture.**

Paper, 150 pages, fully illustrated. This is Terry's latest small book, and has received some very high words of praise. Who among rural people does not have a little garden-plot? If you would learn to raise in it that most luscious of all fruit, the strawberry, with the best results, you can not be without this little book. Even if you don't grow strawberries you will be the better for reading it.

**Tomato Culture.**

In three parts. By J. W. Day, D. Cummins, and A. I. Root. Paper, 150 pages, illustrated. A most valuable treatise embracing field culture, forcing under glass, and raising plants for market. Valuable to any one raising garden stuff of any kind, aside from tomatoes. Price 40c, postpaid.

**Tile Drainage**

By W. L. Chamberlain. This is a valuable companion to our other rural books. It embraces the experience of forty years of one of our foremost practical agriculturists, who has laid with his own hands over 15 miles of tile. Paper, 150 pages, illustrated. Price 40c, postpaid.

**What to Do, and How to be Happy**

**While Doing It.** This is a book of 190 octavo pages same size as this, and 80 illustrations, written by A. I. Root; especially helpful to those out of employment or to those who have a hard time in making both ends meet. How to find something to do right at home instead of going to the already too crowded cities. How to be your own boss and enjoy your work. The true secret of real enjoyment in work. This book will well repay a careful reading. Price, in paper covers, 50 cents.

**ANY THREE** of the following books given for one new subscriber and your own renewal with \$2.00, or any one given for your own renewal with \$1.00. By mail, add 5 cts. each for postage.

**A B C of Carp Culture.**

In paper covers, illustrated. This is a work of 70 pages, 7x10, written by Geo. Finley and A. I. Root, and the best authority on the subject of carp culture yet in print. The rearing of carp is a pleasant and profitable amusement. This book will tell you all about it. Price 30c.

**Winter Care of Horses and**

**Cattle.** This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages, 7x10, illustrated. Price 30c, postpaid.

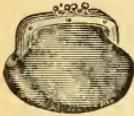

**Maple Sugar and the Sugar-Bush.**

By A. J. Cook. Paper, 44 pages, 7x10, illustrated. This is most valuable to all who are interested in the product of our sugar maples. No one who makes maple sugar or syrup should be without it. If you don't make maple syrup you may want to know how it is made, and how to judge of a good article when you buy it. Price 30c, postpaid.

Some choice bargains in purses. Any one of the following would make a handsome present.

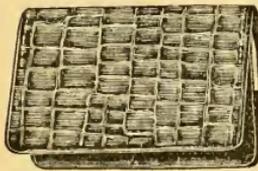

**Alligator Coin-purse;** medium size, nickel frame, gusset ends; usually sold at 20 cents. Each 12; dozen \$1.25; postage, each 4c. Six given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.00.

**Farmers' Prosperity Purse.** "Hides plenty." Genuine buckskin or black kid; Jumb size; three roomy pockets; heavy nickel, firm, ball frame. Each 15c. dozen \$1.50; postage, each, 5c. Five given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.05.

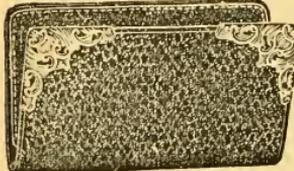

**Monkey-skin Specie-purse.** Faced with leather. This purse is made from genuine monkey skin and comes in assorted colors; handsome two-ball frame, an Al purse in every respect, as well as a curiosity. Each 25c; dozen \$2.50; postage, each, 4c. Three given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Risses' Seal Leather Combination Book.**

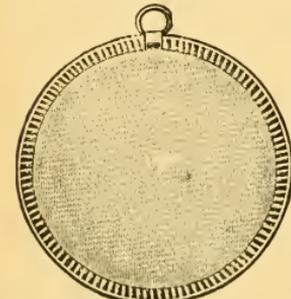

Size 3 x 4 1/2 inches; inside faced with leather; coin pocket with nickel-plated snap frame and two regular pockets; gusseted card-pocket with flap and tuck-strap and one regular pocket. A handsome present for any young lady. Each 35c; postage 5c. Two given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.10.

**Seal Grained-leather Combination Book.**

Fancy metal corners; leather-faced card-pocket in flap; coin pocket with snap frame and three regular pockets; size 3 x 4 1/2. Each 25c; dozen \$2.50; postage, each, 5c. Three given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Our Christmas Token Book.** Real seal-grained leather combination book. One of the neatest books on the market; size and description as above, but better material and finish. Each 50c. Two given for one new subscriber and your own renewal with \$2.25, or one for your own renewal with \$1.25.

**Original Augite Stove-mat.** Absolutely indestructible. Food cooked on it does not scorch or burn. Specially good for oatmeal, rice, milk, or custard. Diameter nine inches, in border; not the cheap worthless mats that are made by some, but the identical mat we formerly sold at 25 cents each. Each 5c; dozen 35c; gross \$3.50; post. 5c. Two dozen given for one new subscriber and your own renewal with \$2.00, or one dozen postpaid for one new subscriber and your own renewal with \$2.00, or 1/2 dozen given for your own renewal with \$1.00, or three postpaid for your own renewal with \$1.00.

**Thimble, German-silver.** Regular goods; standard quality, open or closed ends. Each 5c; dozen 45c; postage, each, 2c. Five given for your own renewal with \$1.00.

**Thimble, Aluminum.** Is very light, bright, and durable; closed end only. Each 5c; per dozen 40c; postage, each, 2c. Five given for your own renewal with \$1.00.

**Thimble, Coin-silver.** Very neat design; would make a handsome Christmas present; open or closed end. Each 20c; dozen \$2.00; postage, each, 3c. Three sent postpaid for one new subscriber and your own renewal with \$2.00, or one sent postpaid for your own renewal with \$1.00.

**Base-balls, "Boys' Lively."** Each 10c; dozen 95c; postage, each, 7c. Two given for your own renewal with \$1.00.

**Base-balls, "League Junior, Spaulding's."** Each 25c; dozen \$2.50; postage, each, 8c. One given for your own renewal with \$1.00.

**Harmonica, "Quarter Drive."** Each 25c; dozen \$2.50; post, each, 3c. Three given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Bay-rum Soap,** for making the skin tender and preventing chapped hands. A handsome cake, purest of milled soap. Box of 3 cakes, 25c; cake, 10c; dozen \$1.00; postage, a box, 15c.

Three boxes given for one new subscriber and your own renewal with \$2.00, or one box given for your own renewal with \$1.00.

**Yankee Shaving-soap.** Too well known to need a description. Cake 10c; dozen \$1.00; postage, each, 3c. Two cakes for your own renewal with \$1.00.

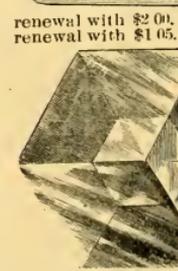

**Shaving-brush, "Barbers' Best."** A genuine good brush. Each 25c; postage 4c. Given for your own renewal with \$1.00.

**Stereoscope.** Neat wood frame and imitation rosewood head with sliding bar, full size, good lens, an excellent offer for a quarter. Each 25c; dozen \$2.00; postage, each, 15c. One given for your own renewal with \$1.00.

**Stereoscopic Views.** A choice variety of foreign or American views. Specify which in ordering. Each 3c; dozen 30c; 100 for \$2.00; post., each, 2c. 2 1/2 dozen given for one new subscriber and your own renewal with \$2.00, or one dozen given for your own renewal with \$1.05.

**Paper-weight, "Dodecahedron."** Several years ago we made a special importation from Germany of 1000 beautiful glass paper-weights. Nothing would be more appropriate for a bee-keeper, as it illustrates the mathematics of the honey-cell to perfection. No matter which way you may happen to turn it you will be delighted by new beauties. When we found it in Chicago it was retailing at 80 cents; but buying 1000 of them we got them at a figure that enables us to sell them at 15c; doz. \$1.65; postage, each, 3c. Four given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Rubber Goods.**

We guarantee these goods to be strictly "firsts," the same quality that is usually sold by druggists at double these prices. Our large output in rubber goods keeps our stock fresh throughout the year, as the stock is constantly changing and new goods arriving almost weekly from the factory. Many dealers sell worthless rubber goods unknowingly, as they become rotten when carried in stock any great length of time.

**Hard rubber Bulb Syringe.** Made of the best white rubber, with solid suction-pipe, and three pieces of hard-rubber fittings. Each in fancy box, 50c; postage 8c. Sent postpaid for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.30.

**Hot water Bags.** A comfort in time of sickness; in fact, an article that is now considered indispensable to every well-organized household. 2-qt. size, each 70c; postage 15c. 3-qt. size, each 75c; postage 17c. 4-qt. size, each 80c; postage 19c. Or any of the above given for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.50.

**Combination Water-bottle and Fountain Syringe.** EX act shape as hot-water bag, with three piece set of hard-rubber fittings and long rubber tube in addition. 2-qt. size, each 95c; postage 20c. 3-qt. size, each \$1.00; postage 21c. 4-qt. size, each \$1.10; postage 22c.

Any of the above given for one new subscriber and your own renewal with \$2.25, or your own renewal with \$1.80.

**Fountain Syringe.** Made from the best white rubber, with hard-rubber connections; regular number of feet of rubber pipe, patent water stop. 2 qt., each 85c; postage 13c. 3 qt., each 95c; postage 15c. 4 qt., each \$1; postage 17c. Any of the above given for one new subscriber and your own renewal with \$2.20, or for your own renewal with \$1.70.

**Hardware Specialties.**

**Kitchen - Knife, Tyler.** Particularly adapted to the work of chopping potatoes while warming.

turning griddle-cakes, eggs, fish, omelets, etc., removing cookies from tin, and many other uses. Each 10c; dozen 75; postage 5c. Seven given for your own renewal with \$2.00, or three given for your own renewal with \$1.00.

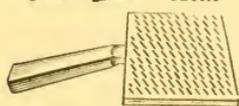

**Fruit-press, vegetable- and potato masher.** The cut shows this most useful

strainer, adjoining useful household utensil in the act of mashing potatoes. You have no idea how much lighter and nicer they are after this process. It is also most valuable for pressing fruit for jelly or jam. Each 35c; dozen \$3.75; box of three doz., \$10.10 postage each, 20c.

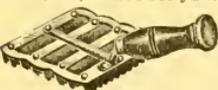

Five given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.10.

**Ink stand.** Bronzed iron frame and hinged cover; glass well; a good sensible ink-stand. Each 10c; dozen \$1.00. Seven given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.00.

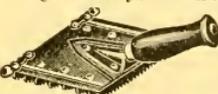

**Cattle card.** For cattle and horses. Solid block; good strong handle. Each 5c; dozen 45c; postage, each, 5c. One dozen given for one new subscriber and your own renewal with \$2.00, or five for your own renewal with \$1.00.

**Currycomb, No. 1.** 8-bar "Lader." Excellent handle, extra heavy and well braced, open back. Each 10c; doz. 88c; post., each, 9c. Seven given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.00.

**Currycomb, No. 2.** "Felpise" 5-center, five-bar, jawed; two heavy wires running through bars and over the back. Each 5c; dozen 48c; postage 6c. Five given for your own renewal with \$1.00.

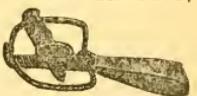

**Currycomb, No. 3.** 8-bar closed back, well finished, enamel handle, extra strong. Each 15c; dozen \$1.50; post., each, 22c. Five given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.05.

**Coffee-mill, "Pulverizer."** A rapid grinder. Full-size, lacquered copper-bronze castings, varnished hardwood box. This is the same mill we have formerly sold at 75c. Each 50c; dozen \$4.75. One given for your own renewal with \$1.25.

**Steel Trap, No. 1.** Jaws spread three and one-half inches; unusually sharp spring; useful for rats,

gophers, and other small animals. Each 10c; dozen 95c; post., each, 6c. Seven given for one new subscriber and your own renewal with \$2.00, or two given for your own renewal with \$1.00.

**Steel Trap, No. 2, "Protector."** Size for muskrats, skunks, woodchucks, etc., or to use in poultry-house and barn. Spread of jaws, 4 inches. Each, with chain, 15c; dozen \$1.45; postage, each, 8c. Five given for one new subscriber and your own renewal with \$2.00, or two given for your own renewal with \$1.05.

**Apple Paring, Coring, and Slicing Machine.** No farm-house should be without one of these machines. It pares, cores, and slices the fruit. Apple and core are pushed off separately. Each 45c; dozen \$4.50 post., each, 25c. Two given for one new subscriber and your own renewal with \$2.20, or one given for your own renewal with \$1.20.

**Flatirons.** Mrs. Potts' pattern, all nickel-plated. Set comprises 3 double-pointed irons, a assorted sizes; retractable, always-cool handle, and iron stand. Do not confuse these with the cheap

polished irons now on the market. Per set of three irons, handle, and stand, 75c. Given for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.50.

**Extra Handles** for the above irons. Each 10c; dozen \$1.00; postage, each, 11c.

### Barney & Berry Skates.

There's nothing new or novel about these except our price, which is to a cent what retail dealers pay for these goods. Nothing will please a boy more for a Christmas present than a pair of B. & B. skates. The 32-cent values are the same as are usually sold at 85 cents.

Table giving sizes of skates in inches, with the corresponding number of shoes.

**No. 1, "Boy's Favorite," Club-lever Skate,** made with cast-steel blades, polished crucible-steel upper parts, model same as highest grade. Sizes 8 to 12. Per pair, only 32c; postage 36c. Given for your own renewal with \$1.10.

**No. A N, "Boys' Favorite," Club-lever Skate,** nickel plated, otherwise as above. Per pair 54c; postage 37c. Given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.30.

**No. Z N, "Boys' Pride," Club-lever Skate,** solid cast-steel blades, hardened, nickel-plated, upper parts of crucible steel; a bright strong skate, without an equal for the money. Sizes 8 to 12. Per pair, \$1.05; postage 40c. Given for one new subscriber and your own renewal with \$2.30, or your own renewal with \$1.80.

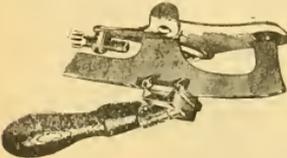

**No. 2, American Club Skate,** nickel-plated, grade 2, welded steel blades, tempered upper parts of crucible steel. Sizes 9 to 12 inches. Per pair, \$1.88; postage 40c. Given for one new subscriber and your own renewal, with \$3.10, or your own renewal with \$2.60.

**No. 2L, Ladies' Skate,** blades of best cast steel, polished crucible-steel upper parts; russet-leather heel and toe straps. Sizes 8 to 10 inches. Per pair, 65c; postage 36c. Given for one new subscriber and your own renewal, with \$2.00, or your own renewal with \$1.40.

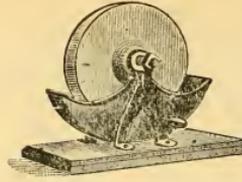

**No. LA, Ladies' Skate,** cast-steel blades, polished crucible-steel upper parts; russet-grained leather straps, with nickel heel-bands. Sizes 8 to 10½ inches. Per pair, 88c; postage 37c. Given for one new subscriber and your own renewal, with \$2.15, or your own renewal with \$1.65.

**No. LZ, Ladies' Skate.** "Nothing better made," solid cast steel, hardened blades, polished upper parts, crucible steel, russet-grained leather, nickel heel-bands; full nickel-plated. Sizes 8½ to 10½ in. Per pair, \$2.25; postage 40c. Given for one new subscriber and your own renewal, with \$3.50, or your own renewal with \$3.00.

**The Diamond Skate-sharpener.** The illustration shows something entirely new in a skate-sharpener. With one of these every boy can sharpen his own skates; usually sold at 25c; our price 20c each; dozen \$2.00; postage 5c. Given for your own renewal with \$1.00.

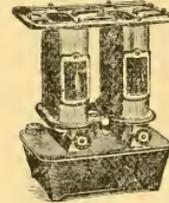

**Family Grindstones, 6-inch.** No kitchen should be without one of these every-day helps. With one of these your wife can sharpen the knives, etc., without your help. This fact alone ought to place one in every kitchen. They are made with iron frame, trough, and crank. The entire mountings nicely japanned. Each 50; dozen \$4.25. Two given for one new subscriber and your own renewal with \$2.25, or one for your own renewal with \$1.25.

**Family Grindstone, 8-inch.** Each 60c; doz. \$6.00. One given for your own renewal with \$1.35.

**Shaft Chime-bells, No. 1.** Made from wrought metal, of superior tone and finish. Nickel-plated and polished. Riveted on iron straps, 3 bells on a strap, two straps in set. Set 75c. Given for one new subscriber and your own renewal with \$2.00, or given for your own renewal with \$1.50.

**Shaft Chime-bells, No. 2.** Swiss chime, harmonized and tuned, 4 bells on a strap, two straps in set. Set \$2.00. Given for one new subscriber and your own renewal with \$3.25, or given for your own renewal with \$2.75.

**Lamp Stove, 1-burner.** Single lamp with 4-inch burner, removable mica front, for giving light. Each 40c. Two given for one new subscriber and your own renewal with \$2.05, or one given for your own renewal with \$1.15.

**Lamp Stove, 2-burner.** Two four-inch burners with wicks, otherwise as above. Each 75c. Given for one new subscriber and your own renewal with \$2.00, or for your own renewal

with \$1.50.

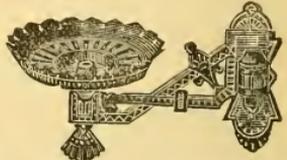

**Lamp Stove, 3-burner.** Three 4-inch wicks with separate burners. Each \$1.00. Given for one new subscriber and your own renewal with \$2.25, or for your own renewal with \$1.75.

**Wicks, 4-inch,** for the above stoves. Each 3c; dozen 30c; postage, each, 2c.

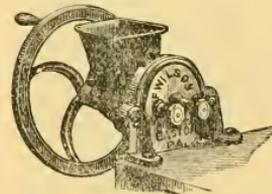

**Flower-pot Bracket, No. 1.** Iron bronzed, artistic design. Each 50c; dozen 50c; postage, each, 9c. Five given for your own renewal with \$1.00.

**Bracket, No. 2,** flower-pot or lamp. Elegant swinging bracket, 5-in. dia. and 6-inch arm. Each 10c; dozen \$1; postage, each, 15c. Seven given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.00.

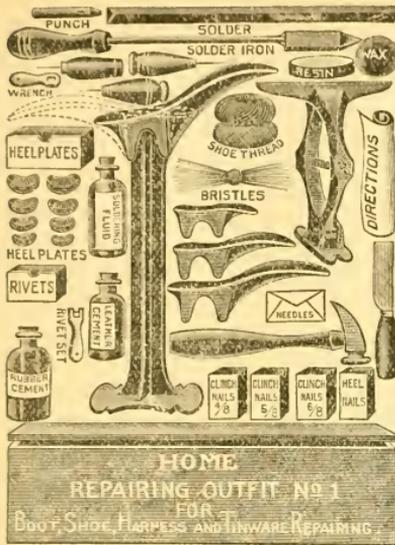

**Wilson's No. 1 Bone-mill.** "A corner-stone to success in the poultry business." Every one who keeps poultry for profit should have some way of pulverizing bones, etc., to aid in the making of shell. We consider this mill the best size for grinding dry bones and shells, crockery, corn, and the like for chicks, crackling wheat or even

making coarse graham for porridge. A circular with testimonials will be mailed free on application. Each \$4.00; with sieve attachment, \$4.50. Given for one new subscriber and your own renewal with \$5.25, or for your own renewal with \$4.75; attachment 50c extra.

**Root's Repairing Outfits.**

**Home Repairing Outfit, No. 1.** A box of ammunition for the battle of economy. Consisting of 44 first-class tools and materials as shown in cut. All these tools are full-sized, practical, neat, and cheap—not mere toys. With one of these outfits any person can do his own half-soling, boot, shoe, rubber, harness, and tinware repairing. Each set, packed in a strong wooden box for safe shipment, weighing 18 lbs. Price \$2.00; half dozen \$10.50. Given for three new subscribers and your own renewal with \$4.25, or for one new subscriber and your own renewal with \$3.25, or for your own renewal with \$2.75.

**Home Repairing Outfit, No. 2.** This is the same set as the above except with the harness and soldering tools left out, and is put up expressly for shoe and boot repairing. Per set, packed in a strong box, \$1.25; half dozen sets \$6.00. Special terms to agents on the above sets in quantities. Given for two new subscribers and your own renewal with \$3.00, or for one new subscriber and your own renewal with \$2.50, or for your own renewal with \$2.00.

**Better Prices on Half-soles.**

We have taken advantage of the leather market by purchasing a large stock just before the advance in price. These are identically the same soles that we and other reliable dealers have heretofore been and are still selling at \$1.75 per dozen. We are now prepared to furnish them for 15 per cent under the market. Please take notice that the dozen price is for assorted sizes, running from 7 to 11. If you want one particular size, the price will be 15c per pair straight through.

**Men's Half-soles.** Nos. 7 to 11. Pair 15c dozen pairs \$1.50; postage, pair, 6c. Five pairs given for one new subscriber and your own renewal with \$2.00, or two pairs for your own renewal with \$1.05.

**Boys' and Youths' Half soles.** Nos. 11 to 6. Pair 12c; dozen pr., \$1.35; post., pr. 4c. Six pairs given for one new subscriber and your own renewal with \$2.00, or two pairs given for your own renewal with \$1.00.

**Women's and Children's Half-soles.** Three sizes (3, 5, and 7). Pair 10c; dozen pairs \$1.00; postage, pair 3c. 20 per cent extra for all No. 7s. Seven pairs given for one new subscriber and your own renewal with \$2.00, or two pairs given for your own renewal with \$1.00.

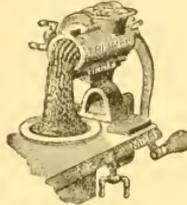

**Clinch Nails.** Put up in k-lb. packages; sizes  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{1}{2}$ . Package 5c; doz. 35c; post., each, 6c. Six packages given for your own renewal with \$1.00.

**Star Heel plates.** Package of 12 dozen pairs, assorted sizes, 10c; post., 5c. Two packages, post paid for your own renewal with \$1.00.  
**Top Heel lifts.** Pair 5c; dozen pairs 50c; post. 3c. Five pairs given for your own renewal with \$1.00.

**Meat-cutters.**

Family meat-cutters are a very great convenience, and well nigh a necessity. Certain it is, that, if properly used, they will pay for themselves in a very little time in any family of ordinary size. There is hardly another item in the list of provisions for the family board that counts up faster than the meat bill; and any thing that will serve to economize in the meat supply, and at the same time render much of it more edible, is certainly worth investigating.

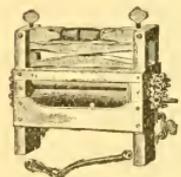

**Triumph Meat-cutter.** This is one of the best cheap machines of the kind on the market. It is also easily taken apart to clean. Each \$1.35. Given for one new subscriber and your own renewal with \$2.00, or given for your own renewal with \$2.10.

**Enterprise Meat-chopper, No. 10.** This machine does not tear the meat, but chops it precisely like the snipping process, like a pair of shears. It is made to clamp to the table by means of a thumb-screw, making it very convenient. This size will chop one pound per minute, and is especially desirable for any one on the meat diet. Each \$2.40. Given for one new subscriber and your own renewal with \$3.65, or your own renewal with \$3.15.

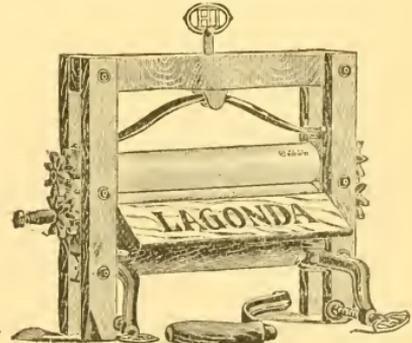

**Sausage-stuffing Attachment,** 35c extra.  
**Extra Knives for the above.** Each 30c; post. 0c.

**Falcon Wringer.**

This is a full-size wringer, and we consider it the best cheap wringer on the market. It has all the improvements of other wood-frame wringers except that the rollers are not pure white rubber, but is well worth the price here asked. Rolls 10x1 1/2 in. Each \$1.25. Given for one new subscriber and your own renewal with \$2.50, or given for your own renewal with \$2.00.

**Lagonda Wringer.**

Extra strong frame; steel spring; best American rolls, vulcanized on the shaft. This wringer is sold the world over at three dollars each. The rolls are warranted to be first class. Each \$2.00; extra rolls \$1.00 each. Given for one new subscriber and your own renewal with \$3.25, or for your own renewal with \$2.75.

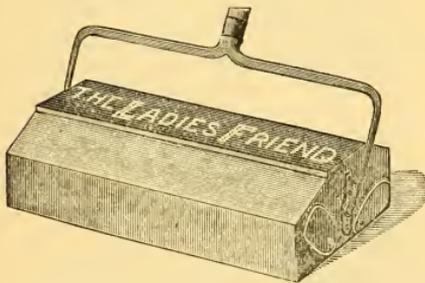

**Crown Raisin-seeder.** We consider this the best machine of its kind on the market, and should be in every family, hotel, bakery, etc. It removes the seeds from all kinds of raisins (big or little) without waste, and makes it heretofore disagreeable work clean and pleasant, and is so simple a child can operate it. It is tinned to prevent from rust; easily cleaned. Each 50c; dozen \$5.00. Two given

for one new subscriber and your own renewal with \$2.25, or one given for your own renewal with \$1.25.

### Carpet-sweepers.

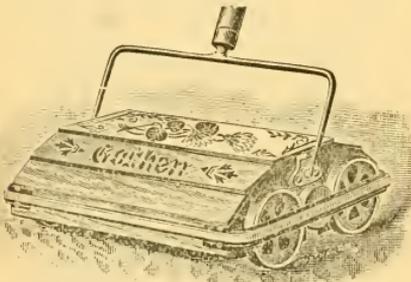

We purchase these goods in gross lots at spot-cash price, hence the price here offered. We have sold this make of sweepers for years and have yet to find any thing better for the money. We especially call your attention to the Goshen, which we have found equal and many instances superior to sweepers sold at retail for three and four dollars each.

#### "Ladies' Friend" Carpet-sweeper.

Oak-finish case; wheel on one side; best quality brush. Mrs. Root has used one of these sweepers for ten years, and does not want any other kind. Each \$1.50. Given for two new subscribers and your own renewal with \$3.25, or for one new subscriber and your own renewal with \$2.75, or your own renewal with \$2.25.

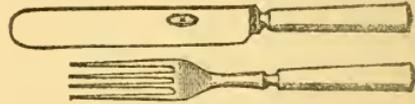

#### "Goshen" Carpet-sweeper.

Light oak finish; four drive wheels; best quality brush; latest style dust-dump; rubber band around it to prevent it from marring the furniture; the easiest-running sweeper out. The best article in the list for Christmas, birthday, and wedding presents. Each \$2.00. Given for two new subscribers and your own renewal with \$3.75, or one new subscriber and your own renewal with \$3.25, or your own renewal with \$2.75.

## SILVERWARE DEPARTMENT.

We handle only the best grade of Rogers silverware, and guarantee the quality. While goods bearing the "Anchor" trade-mark will strip more silver than any other brand of Rogers goods on the market, we guarantee that our prices are as low as any genuine Rogers goods can be purchased for. There is nothing more appropriate for Christmas, wedding, or birthday presents than Rogers' flat tableware. Every one would know the value of a present if it is stamped "Rogers' Anchor brand." One-half dozen at dozen rate.

**Round Medium Knives and Forks.** Knives are triple plated on steel and forks triple plated on nickel silver. We guarantee this set equal to any thing on the market for wear. Per set of six knives and six forks \$3.30; postage 30c.

**Round Medium Knives Only,** as above. Dozen \$3.30; postage 41c.

**Round Medium Forks Only,** as above. Dozen \$3.30; postage 28c.

**Dessert-knives** to match the above. Dozen \$3.20; postage 40c.

**Dessert-forks** to match the above. Dozen \$3.20; postage 20c.

Six knives and six forks, one dozen of any the above, given for six new subscribers and your own renewal with \$7.00, or given for one new subscriber and your own renewal with \$4.55, or your own renewal with \$4.00.

**Butter-knife, triple plated on steel.** Each 35c; dozen \$3.50; postage, each, 4c. Two given for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.10.

**Teaspoon, Tipped Pattern.** best triple plate on nickel silver. Set of 6, \$1.50; postage 8c. Given

for two new subscribers and your own renewal with \$3.25, or your own renewal with \$2.25.

**Dessert-spoons, Tipped Pattern,** best triple plate on nickel silver. Set of six, \$2.50; postage 12c. Given

for four new subscribers and your own renewal with \$5.25, or one new subscriber and your own renewal with \$3.75, or your own renewal with \$3.25.

**Table-spoons, Tipped Pattern,** best triple plate on nickel silver. Set of six, \$3.00, postage, 16c. Given for five new subscribers and your own renewal with \$6.25, or one new subscriber and your own renewal with \$4.25, or your own renewal with \$3.75.

**Sugar-shell, Tipped Pattern,** triple plate on nickel silver; very

handsome, each 70c; postage 3c. Two given for one new subscriber and your own renewal with \$2.25, or one given for your own renewal with \$1.25.

**Sugar-shell, Shell Pattern,** single plate, very handsome. Each 35c; postage 3c. Two given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.10.

**Rogers' Silver-metal Flat Ware,** made by the genuine Rogers' people, who turn out none but good goods. They are made of solid silver metal, and are alike throughout. They are fully as light and handsome in appearance as the high-grade plated goods, and are particularly recommended by the makers for wear. Prices are as follows:

**Teaspoons, Silver-metal.** Set of six, 60c; postage 12c, or given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.35.

**Dessert-spoons, Silver-metal.** Set of six, 90c; postage 14c. Given for one new subscriber and your own renewal with \$2.15, or your renewal with \$1.65.

**Table-spoons, Silver-metal.** Set of six, \$1.20; postage 14c. Given for two new subscribers and your own renewal with \$3.00, or your own renewal with \$1.95.

**Butter-knife, Silver-metal, fancy pattern.** Each 20c; postage 5c. Sent postpaid for your own renewal with \$1.00.

## Honey Column.

## CITY MARKETS.

**MILWAUKEE.**—The condition of this market for honey seems to be favorable. The receipts are good and the demand fair for both comb and extracted, and quality better than in times past. We quote fancy white in 1-lb. sections, 12@13; No. 1, 11@12; fancy amber, 9@10; extracted, in barrels, kegs, and pails, white, 5½@6; amber, 4½@5½; dark, 4@5½; beeswax, 25@27.

Nov. 8.

A. V. BISHOP & Co.,  
Milwaukee, Wis.

**NEW YORK.**—Honey arriving quite freely; trade quite active; market ruled steady at unchanged prices. State white-clover comb, fancy, 12@12½; fair, 10@11; buckwheat, 8@9; white clover, extracted, 5@5½; buckwheat, 4@4½; California comb, 11@13; extracted, 4½@5; Southern, in bulk, per gallon, 3@5; Beeswax in demand; market, 26@27. Write us before making shipment.

Oct. 26.

FRANCIS H. LEGGETT & Co.,  
Franklin and Varick Sts., New York.

**ST. LOUIS.**—There has been no change in the honey market since our last quotations. The demand for honey is still rather slow. The most of our large manufacturing companies have bought largely of western stock. Beeswax, prime, 24@24½.

Nov. 8.

WESTCOTT COMMISSION CO.,  
213 Market St., St. Louis, Mo.

**CINCINNATI.**—Demand is slow for extracted and comb honey, unusually so for this time of year. We quote best white comb honey at 10@13; dark, 7@8; extracted honey brings 3½@4, according to quality. Supply is good of all kinds. There is good demand for beeswax at 22@25, for good to choice yellow, with a fair supply.

Nov. 8.

CHAS. F. MUTH & SON,  
Cincinnati, O.

**CHICAGO.**—Fancy white, 11@12; No. 1 white, 10; best grades of amber, 8@9; fair grades of amber, 7; dark grades or mixed, 7@8; extracted white, 5@6; amber, 4½@5; dark, 3½@4. All of these grades vary in quality and style of package, which makes it difficult to tell just what a certain colored honey will bring without knowing flavor and body thereof. Sales are of small amounts, and supply abundant. Beeswax is wanted at 26@27 on arrival.

Nov. 8.

R. A. BURNETT & Co.,  
163 South Water St., Chicago, Ill.

**NEW YORK.**—Our market does not show much activity, and comb honey is moving off rather slowly. Receipts are large, and the stocks are accumulating. While choice grades of white are likely to find sale at present quotations, prices on off grades and buckwheat will have to be shaded in round lots. We quote fancy white, 12; No. 1, 10@11; amber, 9@9½; buckwheat, 8@8½; extracted California white, 5@5½; California light amber, 4½@5; clover and basswood, 5; Southern, in barrels, in good demand at 50c per gal.; Beeswax finds ready sale at 26@27.

Nov. 8.

HILDRETH BROS. & SEGELKEN,  
120-122 W. Broadway, New York.

**MINNEAPOLIS.**—Fancy white clover, 10@12; No. 1, 9@10½; white extracted, 5@6. Best time of season to ship; stocks can be handled promptly now.

Nov. 8.

S. H. HALL & Co.,  
Minneapolis, Minn.

**SPRINGFIELD.**—Honey in good demand. Fancy white clover, 12c; choice white clover, 10; buckwheat, 10c.

Nov. 7.

PERKINS & HATCH,  
Springfield, Mass.

**CLEVELAND.**—Fancy white, 12@13; No. 1 white, 11@12; fancy amber, 9@10; No. 1, 10@11; amber, 8@9; fancy dark, 7@8; white extracted, 6½; amber, 5½@6; beeswax, 28.

Nov. 9.

A. B. WILLIAMS & Co.,  
80-82 Broadway, Cleveland, Ohio.

**BOSTON.**—Comb honey is moving more freely now. Fancy white, in cartons, 13; No. 1 white, in cartons or glass-front cases, 11@12; fancy light amber, 10; white extracted, 6@7; light amber, 5@5½; beeswax, 28, and wanted.

Nov. 8.

BLAKE, SCOTT & LEE,  
Boston, Mass.

**DETROIT.**—Best white comb honey, 11@12; other grades, 8@10½; extracted white, 5@6; dark, 4@5; beeswax, 25@26.

Nov. 9.

M. H. HUNT, Bell Branch, Mich.

**KANSAS CITY.**—The receipts of comb honey are large; extracted, light; demand fair. We quote fancy white comb, 11@12; No. 1, 10@11; amber, 8@10; extracted white, 5½@6; amber, 5@5½; dark, 4@4½; beeswax, 22@25.

Nov. 8.

C. C. CLEMONS & Co.,  
Kansas City, Mo.

**ALBANY.**—Our market is very active, and stock moving off rapidly. Fancy white is scarce, and we are unable to fill all of our orders for this grade. Buckwheat and mixed are plentiful. There is also a better demand for extracted. We quote fancy white, 13; No. 1, 12@13; buckwheat and mixed, 7@10; extracted dark, 4@4½; amber, 4½@5.

Nov. 9.

CHAS. McCULLOCH & Co.,  
Albany, N. Y.

**COLUMBUS.**—Fancy white, 13; No. 1, 11@11½. There is now existing a very good demand for white comb. Receipts are light. We want honey, and are in the market to buy any quantity. Advise us what you have to offer, stating price and quality.

Nov. 9.

THE COLUMBUS COMMISSION & STORAGE CO.,  
400-413 N. High St., Columbus, O.

**FOR SALE.**—25 blbs. extracted pure white-clover honey, very light in color, and of finest quality, at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

**FOR SALE.**—Alfalfa honey, light amber, in carload lots. 3¼ cts. per lb.; sample, 10 cts.

JOHN NIPPERT, Box 1051, Phoenix, Arizona

**FOR SALE.**—Tons of honey, comb, at 7 to 12c per lb. Inclose stamps for samples of extracted at 4 to 6c, in 100-lb. kegs, f. o. b.

N. L. STEVENS, Venice, N. Y.

**FOR SALE.**—Pure honey.—Clover, extracted, 6½ cts. per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City.

**FOR SALE.**—Good extracted white-clover honey and heartsease and Spanish needle. Either, price 5c per lb., 60-lb. cans, 2 in a case. Send stamps for samples.

JNO. A. THORNTON, Lima, Ills.

## No cheap Queens to sell; but the best.

Golden 5 band, or 3 band from  
imported mother. Untest-  
ed, 75 cts.; tested, \$1.00.

L. BEAUCHAMP, Box 613, San Antonio, Texas.

**BARRLED PLYMOUTH ROCKS,** Hawkins' noted strains. A few choice birds for sale cheap, \$1.00 each.

FRED H. BURDETT, Clifton, N. Y.

**70 COLONIES OF BEES FOR SALE.** In 1½-story Langstroth hives, in good shape, at \$2.50 per colony. Italians and Carniolans.

D. C. HEIDT, Oatston P. O., Barbour Co., Ala.

**FOR SALE**—Green-bone cutter. Good order; can be used with power; bargain.

Box 57, Medina, Ohio.

# The Review at Reduced Rates.

The **Bee-keepers' Review** is \$1.00 a year, but, for the sake of getting it into new hands, and being able to begin the year with a large list, I will, until Jan. 1st, send free to each *new* subscriber, a copy of "Advanced Bee Culture," a 50-cent book of nearly 100 pages, that gives briefly but clearly the best methods of management from the time the bees are put into the cellar in the fall until they are again ready for winter—32 chapters in all. Those who prefer can have, instead of the book, 12 back numbers of the **Review**, the selection to be mine, but no two numbers alike. All who send \$1.00 now will receive the last four issues of this year free, and the **Review** will be sent until the end of 1898. If not acquainted with the **Review**, send 10 cents for three late but different issues.

W. Z. HUTCHINSON, Flint, Mich.

# \$100

Given as **BOUNTIES** to purchasers of the improved Danz. Hives and Sections. For particulars see p. 64, of my book, "Facts about Bees." Mr. M. H. Mendleson, of Ventura, Cal., with 900 colonies, bought 26 of my hives, 500 supers, and 50,000 sections this season, and intends buying many more next. Mr. S. D. Matthews, of Hamilton, N. C., and others, from a few hives, in 3 years, will order hundreds. Mr. J. T. Calvert, treasurer and business manager of the A. I. Root Co., says of Facts, "It is better than bee-books sold for 50 cts." Sent free for 2 cts. in stamps. Address  
F. DANZENBAKER, Washington. D. C.

10 Vine St., Philadelphia, Penn.

Now is the time to order

**Shipping - cases, Winter Cases,  
Chaff Division-boards, etc., etc.**

Order from catalog; prices are same  
as from factory.

**Another  
Great  
Clubbing  
Offer!**

## Two Great Papers at Price of One.

GLEANINGS IN BEE CULTURE  
and the PRAIRIE FARMER (Chi-  
cago), both papers for only \$1.00.

This offer is good either to new name or renewal, but in case of renewal all back subscription must be paid up in addition to the \$1 for the two papers. The *Prairie Farmer* is one of the leading farm papers, and is clean in both the reading and advertising pages.

Address All Orders to

**THE A. I. ROOT CO.,** Medina, Ohio.

## Shipping=cases.

Root's popular Non-drip Shipping-cases at factory prices at DES MOINES, IOWA. Immense stock. All orders for cases or other goods shipped by return freight. Address

JOS. NYSEWANDER, Des Moines, Iowa.

## Weekly Bee Journal One Year for 25c.

To every *new* subscriber who sends us \$1.50 before Jan. 1, 1898, we will mail a copy of Prof. Cook's 400-page cloth-bound book, "BEE-KEEPERS' GUIDE" (price \$1.25), and the **Weekly American Bee Journal** for one year. That makes the **Journal** only 25 cents—a trifle less than half a cent per number. Or, if any one now getting the **Bee Journal**, and whose subscription is paid to Jan. 1, 1898, will send us \$1.50, with a new name, we will mail the above book to the sender, and the **Bee Journal** for a year to the new name and address. We need hardly tell you what the **American Bee Journal** is; but if you are not acquainted with it, *write us for a free sample copy.*

# GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

Published by THE A. I. ROOT CO.  
\$1.00 PER YEAR MEDINA, OHIO.

VOL. XXV.

NOV. 15, 1897.

NO. 22.

## STRAY STRAWS

FROM DR. C. C. MILLER.

ULR. GUBLER, who writes the monthly counsels for beginners in *Revue Internationale*, says he has found by years of trial that bees winter better in hives not painted. I believe Doolittle stands on the same ground. I want covers painted, but not bodies.

The *Busy Bee* for October is devoted almost entirely to sweet clover, the shears being freely used on GLEANINGS for that purpose; and, as showing progress, the present attitude of GLEANINGS is contrasted with that of five years ago, when an editorial said, "Sweet clover is not a success with us for fodder or feed at all, although stock will eat it to some extent if cut just at the right time."

LAST YEAR I said, "If paraffine is left untouched by bees, why not apply a coating of it to ends of top-bars and other points we don't want glued?" Ignoring that first word "if," an item has been going the rounds of the German bee-journals that painting with paraffine would prevent gluing. There is now no "if" in the case. Bees *will* daub propolis on paraffine. Sehen Sie, meine guten deutschen Freunde?

A WRITER in one of the German bee-journals thinks bee conventions will be better if discussions are held with wine-cup in hand. It doesn't work that way over here. At Buffalo, a man who had evidently had the wine-cup or some other cup a bit too much in hand, seemed to be trying to hinder useful discussion. His friends should put a seal on his lips in conventions hereafter, or else keep close watch on what passes his lips before coming.

"DON'T FORGET that *very few* people get tired of first-class honey; and, above all, remember that almost any one will tire of poor, thin, unripe honey." That's what Dan White said, p. 767, but it's time it was said over again. That story of his almost makes me want to raise extracted honey so I can peddle it. [Yes, indeed. This is one of the truths that should be passed around. If it could only take wing like an unmitigated malicious lie, it would do the world a lot of good.

There is too much slipshodness in harvesting and marketing honey.—ED.]

I ARISE TO REMARK in a very subdued tone, that, much as I like the groove in the bellows-board, I don't think it's *quite* equal to a  $\frac{1}{4}$  x  $\frac{1}{8}$ -inch cleat. [Perhaps. But the groove looks so much neater, and is so much easier to apply, from a manufacturer's point of view, that the little cleats could hardly be considered. But for the life of me I can not see why a groove is not just as good if made deep enough. Possibly ours are not deep enough.—ED.]

I DON'T KNOW for sure just why sections this year should be half an ounce lighter than last. Something might be due to the fact that empty sections were furnished more freely than last year. July 1 there was an average of nearly four supers to each colony in one apiary. But the honey-flow has much to do with the weight of sections. Sometimes the upper two-thirds of a section will be sealed, the section being rather thin, then comes a change in the harvest, and the lower third looks bulged.

ACETYLENE GAS. After reading what A. I. Root said about this, I determined to have it in my house just as soon as it could be had. According to the *Cosmopolitan*, however, it is dangerously explosive. I don't believe I want it. [Yes, and from recent reports in other periodicals it would seem as if this new gas could never be used for domestic lighting. By the way, doctor, the members of the Root firm are just equipping their houses with electric lights, the current coming from the factory. If you will move down close beside us we will give you some of the same sort of "juice."—ED.] [Doctor, see p. 791.—A. I. R.]

SOME TIME within the past five years a smoker-hook like that on p. 779 was sent me, asking about patenting it. I said it couldn't be patented—old. I wish I could remember where it was first described—was it in GLEANINGS? At any rate I used it years and years ago, but got tired of it. Still, some will like it. [Yes, I am quite certain that the hook was illustrated in GLEANINGS; but no enterprising manufacturer at that time probably thought enough of it to have it supplied with his regular stock. It does not stand in the way if one does not care to use it; and on the

other hand it may be a very great convenience. I have been trying it a little myself, and must say I like it.—ED.]

OH THE DROUTH! Three months ago the earth was a mat of white clover; to-day, Nov. 1, you must get down on hands and knees to find it, and some places none then. [I am afraid, doctor, there is a good deal of truth in what you say; and I am afraid, too, that the condition you observe will be found generally over the country. Whether that will have the effect of cutting down the growth of clover next summer, remains to be seen. We have just had two or three days of rain—raining almost constantly. It always rains, you know, during election. Possibly the rains may help to revive the drooping spirits of the clovers now almost out of sight, even if it does not those of some of the politicians, surely buried for ever out of sight.—ED.]

I AGREE with you, Mr. Editor, p. 766, that bees put more wax in combs in a dull flow, but I always supposed that such wax was the regular article, and I never heard proof that any of it was lugged in from outside on their legs. [It may be that bees do not use "gathered" wax to thicken combs in dull seasons. But we do know that they will darken a nice light comb put up next to a dark one; and the only way we can account for this darkening is on the ground that the bees borrow wax from the old comb and put it on the new. I should be more inclined to believe that bees follow no invariable rule—that wax is wax to them, whether it be the regular article coming in the regular way or that which has been borrowed or stolen.—ED.]

THE GERMAN BEE-KEEPERS' Central Association at present numbers about 25,000 members. As far back as I can remember, no bee-keepers' society in this country ever reached that number. [No, nor anywhere near it; and yet the U. S. B. K. U. ought to have at least that many names to back it up. Why is it that there is such apathy on the part of bee-keepers? Only the other day I received a letter from a man who thought we ought to do less talking and do more work in the matter of fighting adulteration; but I am almost certain he is not a member of the U. S. B. K. U. Many of these fellows who talk about "action" and "less talk" are just the very ones who grumble, and yet never would think of putting their shoulder to the wheel themselves.—ED.]

WHILE HAULING bees home, a little episode broke in on the even tenor of my life. I made a rack, and put it on top of a heavy wagon-box—springs under—31 colonies at a load. Unloading I stood on top and handed hives to Philo. When the last hive was left on the rack, extending over the hind end, my weight, together with the hive, overbalanced the rack, and it tipped. The hive lit on ground upside down; I fell on my back; rack fell on me; rack wasn't hurt a bit. [It is too bad, doctor, there was not a Kodaker around to preserve the whole situation. If you will agree to go through with the performance again I will promise to take a series of snap shots, even if

I have to go clear to Marengo. But say, doctor, I should like to know what was the temper of the bees, and possibly of *yourself*, about the time you all three came down "ker slap."—ED.]

REPLYING to your question, p. 767, I didn't cushion down the paraffined paper. Didn't need to. Bees glued it down. The only point I made was that bees would put glue freely on a paraffine surface, in contradiction of the claim made in GLEANINGS for 1896, p. 756, that bees dislike paraffine and are not inclined to deposit propolis on it. [If you had cushioned down the paper there would have been less propolis, I am almost sure, doctor. Mr. Danzenbaker insists that paraffine paper should be squeezed down tight to the surface of the sections. If there is a little crack or air-gap, as there certainly must have been between the sections and the paraffine paper that you put over your sections, propolis would certainly be put in to fill up the spaces. But I think we might just as well admit that bees do not dislike paraffine paper as much as we thought they did; and we certainly can not now say that they will not gnaw it under some circumstances.—ED.]

THAT FOOTNOTE, p. 766, seems to help the boom for figwort, although it was hardly so intended. But when you say, "Our own experience, so far as I can remember," that phrase, "so far as I can remember," makes your cultivation of the plant only a memory. Please tell us how much land you have now occupied with figwort, and how much less with sweet clover. In plain words, is it advisable to occupy good land with figwort? [Figwort grows wild in our river-bottom land, or it did do so a few years ago when we were specially interested in studying this plant. The only point I tried to make was that there is more honey—considerably more of it—to a single stalk of figwort, than in a stalk of sweet clover. In answer to your question I would say that it would not pay to try to grow either one on good ground. No, we are not growing figwort on our land, neither are we trying to grow sweet clover; but, unlike figwort, it will of its own sweet will, spring up and thrive in all waste places. No scythe on our premises dare molest it.—ED.]

IN REPLY to your implied question on page 766, Mr. Editor, I don't know just how many days' work was involved in getting that crop of 17,150 lbs. of honey; but I know that two of us did all the work except perhaps what might be equivalent to two months' work. Neither did I spend my whole time at it, for I furnished weekly to bee and agricultural journals some half a dozen columns of stuff about bees—in fact, not such a very light year's work at writing alone. But I had to get up at three and four in the morning through a good part of the harvest; and if I'd been less young and tough I couldn't have stood it. [I do not understand you, doctor. You say, "I know that two of us did all the work except perhaps what may be equivalent to two months' work." Do you mean that you practically harvested that whole crop, two of you,

in the equivalent of two months? or that two of you spent ten months, leaving out the other two months which you apparently except? or what do you mean? It would be very interesting indeed to know approximately just how many days it took to harvest that crop; and if two of you did it practically in 60 days, it was a big feat indeed. It is possible that many bee-keepers are spending too much time in getting a given crop of honey; and if you have broken the record, let us hold it up high until some one else breaks it.—ED.]

### G. M. DOOLITTLE IN HIS APIARY.

#### Testing Honey from Deep-cell Foundation.

BY ERNEST R. ROOT.

After the Buffalo convention I told Mr. Doolittle that I should probably call upon him in a week or so. But circumstances made it

this deserved title; and before I go further I am going to give you right here what Mr. H. has to say about our friend:

Doolittle was certainly what GLEANINGS called him, the "uncrowned king of the Buffalo convention." I think no one will be offended if I say that I think that he was the best speaker there was there. No one who has simply read his staid, sober, matter-of-fact articles in the bee-journals would dream of the manner in which he can flavor his speeches with anecdote and illustration. For instance, he was telling how some old man was working himself all but to death that his children might not be compelled to begin at the foot of the ladder as he had done. Mr. Doolittle asked him if he had not enjoyed himself when he began house-keeping in a humble way, and he and his young wife had worked cheerfully and happily as month by month they added to the comforts of their home. The old man was silent a minute and then admitted, "They were the happiest days of my life." "Would you rob your children of this happiness?" asked Mr. Doolittle. I don't suppose Mr. Doolittle knew it, but it brought tears to my eyes, so clearly did it bring back those happy days when wife and I began housekeeping in a humble home built by my own hands, and "worked cheerfully and happily as month by month we added to the comforts of our home."

Mr. Salisbury and I oiled up our wheels the night before, and the next morning donned

DOOLITTLE AND SALISBURY SAMPLING COMB HONEY FROM DRAWN FOUNDATION.

necessary for me to change my plans; and the consequence was, it was not till the 5th or 6th of September that I found it possible to make my proposed visit. Having made a tour in and around Seneca Co. and Seneca Lake, Tompkins Co. and Cayuga Lake, I made my way northward to Syracuse, intending at that point to ask Mr. Frank A. Salisbury, our branch manager, to accompany me out to see "the uncrowned king of the Buffalo convention." And this reminds me that the editor of the *Review*, Mr. Hutchinson, fully indorses

our knickerbockers, golfs, and sweaters, preparatory to a twenty-five-mile ride to Borodino. The morning was all that could be asked for; and then began the heavy grinds up the hills, followed by almost mile-a-minute coasts down the other sides of the grades. Frank knew better than I how to take advantage of the hills about Syracuse, and he certainly knew how to let his wheel "go gallagher" down these long coasts. I did not dare to let mine out at such break-neck speeds; and the consequence was, when we came to a level

stretch I had to do some hard pedaling to make up.

On we sped, over hills and valleys, till we came to Rose Hill, where that great seedsman, Mr. F. B. Mills, lives. Mr. M. has here an immense seed-farm, fine buildings, and beau-

tiful. I did not realize we were making such time till Mr. Salisbury called out, pointing over to the left. "There is Doolittle's!"

I had given our Borodino friend no intimation that we expected to call on him that day. Indeed, I was not sure he would be at home.

DOOLITTLE AND HIS FAVORITE FIVE-BANDED BEES.

tiful surroundings. But as we were in a hurry we did not stop.

Mr. Salisbury, ahead as usual, put his feet up on his coasters, and let his wheel go, and I did likewise. The long easy coast down the hill, almost flying through the air, was most

As he was away from the railroad I could not reach him by telegram the day before, and accordingly took my chances. With some doubts Frank and I, covered with dust and sweat, stalked into the yard, when who should meet us but the "king" himself? Instead of

the "crown," he had on an old straw hat and old clothes ready for work in the apiary.

"Well," said Mr. Doolittle cordially, "this is rather unexpected."

"All the better," I said. "We have caught you, not as you would be, perhaps, to receive company, but just as you are every day in the apiary." I told Mr. Doolittle that I had come to do some kodaking as well as to talk bees, and I asked if he would have any objections to my taking a photo of him just as he stood. "Not at all, sir; I am at your service."

We then walked over to his hive of five-banders that have the extra choice breeding-queen. Lifting a frame out he held it up before us and remarked, "How do those bees suit you?"

As he did so I took a shot. The large view accompanying shows him just as he stood. He had opened the hive without smoke, without veil, and the frame was pulled out in a way that would be regarded as a decided intrusion by some bees. But these great big yellow bees went right on with their work just the same, apparently, without observing it.

The lights and shades in the picture are rather strong, owing to the fact that Mr. D.'s apiary is in an orchard, and the hive before which he stood was in the open.

Mr. Doolittle does not believe in wearing fine clothes out among his bees, especially when he is not expecting visitors; and if you will look sharp in the bottom of the picture you will see he tucks his pants down his stockings, to keep out crawling bees. Many a man, possibly, would object strenuously to being "shown up" before the readers of GLEANINGS, in every-day attire; but Mr. Doolittle said he was not ashamed to be seen in work-clothes.

After we had looked at the beautiful bees, and heard Mr. Doolittle tell how these yellow banders, unlike ordinary Italians, would cap their honey as white as do the blacks, we repaired to his shop, there to look over samples of his honey produced from the drawn or deep-cell foundation, to which Mr. Doolittle has already referred in one of his articles. He had kept these samples for me to try, when I should come. He procured a plate and case-knife, and together we repaired to a cool place under one of the large spreading apple-trees. We first tried the chewing quality of a sample made from drawn foundation, and then a sample made from ordinary foundation. It was evident that there was more midrib on the new product than on the old.

While Messrs. Doolittle and Salisbury were sampling, I, with my fingers all sticky with honey, grabbed up the camera and took a shot, and the result reduced to half-tone is also shown.

You will notice that Mr. Doolittle uses a tall section, and the same are held in wide frames while on the hive. He has been using these deep sections for years, if I am correct; and although I forgot to ask him *why* he did not use the regulation  $4\frac{1}{4}$ , the reason is, no doubt, owing to the fact that his markets call for these tall boxes; and as long as they bring a

little higher price, he will, of course, continue to use them.

About this time we were called to dinner; and, with appetites whetted to the keen by the ride, Mr. Salisbury and I enjoyed Mrs. Doolittle's excellent dinner. After a most delightful chat, on bees and the issues of the day (for Mr. D. has given much thought to some of the great sociological problems of our times), Mr. S. and I took another route back to Syracuse. He led off as usual. We passed through Marcellus, where N. N. Betsinger once lived. Frank pointed out to me the beautiful home Mr. B. once owned, but which, with every thing else, had been swept away in a lawsuit. Whether Mr. Betsinger was guilty of the awful crime of which he was accused, and for which he was tried, we shall, perhaps, never know. I do not remember exactly the result of one or more lawsuits. I believe, however, the jury disagreed. The affair is a most sad one, and the lawyers reaped a harvest.

Winding around the river we came to Camillus. At present there is there a Mr. House, a bee-keeper, a brother of George W. House, formerly one of the editors of the *American Apiculturist* in its palmiest days. Mr. House has a most beautiful location for an apiary. Just back of his dwelling is a sort of ravine where his apiary is kept between two of those big hills for which York State is famous. As I have before stated, I took a Kodak view, but, most unfortunately, it was so late in the day it did not develop up as it should. But there is not a prettier site in the whole world for an apiary. Possibly Mr. House will favor us with a photo of his yard at some future time.

Leaving here, Mr. Salisbury took the lead as usual; but I noticed that his legs were beginning to give out. He had not been used to such long rides as I had, and was not standing the trip quite as well, and I was just beginning to wonder whether I hadn't better push him with my wheel, when he made an extra spurt, and in a short time we landed at the top of a long hill, and coasted almost into Syracuse.

Frank is one whom it is a pleasure to know. He is rather quiet in his manner; and if the other fellow will do the talking, he will keep still, occasionally throwing in a word. He is a single man, but I have heard it whispered that one or two nice girls were after him. If they get him he'll be a prize. But the lack of a wife is more than made up by a most excellent mother, whom to know is to love almost as one's own.

---

#### MILES MORTON.

His Comb-Honey Super; His Portable House-Apiary.

BY ERNEST R. ROOT.

Although I have already said a few things concerning friend Morton I have not said all I want to say yet. In the first place I had better formally introduce him—at least so far as

I can do it on paper, and here he is—in half-tone if not in flesh and blood.

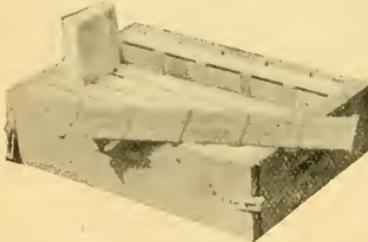

When and where Mr. Miles Morton was born is not particularly important; but it is pertinent to remark that he has been for years using certain devices and practicing methods that to me appear to have been in advance of the times. As his "bee fixin's" had real merit other bee-keepers seeing them wanted them

MILES MORTON.

also, and the result was he simply *had* to make for them what they could not buy at the regular factories. I have already said he has a finely equipped little shop, and from this he has turned out some nice fine work of the Dr. Tinker order. He does not seem to have gone into the manufacturing business so much for the money as an accommodation to his neighbors and friends. Well, this same philanthropic spirit shows itself in his willingness to show me his ideas, knowing that I would give them away to the world.

I have already referred to the salability of his sections; of the cleated separators that he has been using for the last eight or nine years; and I now show you a view of his comb-honey super, a half-tone reproduction from a snap shot that I took while in his apiary.

MORTON'S COMB-HONEY SUPER.

On top of the super is his section, the size of which is just exactly  $3\frac{3}{4} \times 4\frac{3}{4}$ . The section

is four-piece, having practically no bee-space on either side, as I have already explained, the bee-space itself being formed by the cleats on the separators themselves. The size of this section is regulated by the fact that his regular L. hive is  $18\frac{1}{2}$  inches long inside; and this length, divided by five, gives  $3\frac{3}{4}$ . The super itself, being of the same length, is made enough deeper to give a nice proportionate height to the section; for the York Staters, you know, have a strong inclination toward a tall or deep section.

As I have already said, the cross-cleats on the separator are held on simply by ordinary cabinet-makers' glue. In all the years that Mr. Morton has been using this separator, not once has one of these glued strips come off. As you already know, this separator pleases us so well that we have practically adopted it for our 1898 separators, for plain  $4\frac{1}{4}$  sections without bee-ways.\*

These sections in Morton's super are supported on slats, spaced and fixed at the proper distance; and the top edge of the sections comes flush with the top edge of the super. When there is only one super on the hive, enamel cloth is laid directly on top of the sections. If there is to be more than one, a sort of honey-board having slats corresponding to the top of the sections is laid on top, there being no bee-space between the sections and the slats. On the top side of this honey-board there is a bee-space that provides for the usual space under the next super above.

It will thus be seen that the top and bottom of the sections are entirely covered, whether the super is used singly or tiered up. While I can not bring myself to believe that thus covering the tops of the sections is just exactly the thing, I am not prepared to say that Mr. Morton is all wrong; for on the principle of "by their fruits ye shall know them," his honey is in every respect first-class.

Another unique feature of this super is a tightening-side, two long screws being passed freely through the center at each end of this side into the center of the ends; and these screwheads stick out far enough to permit of the use of an ingenious metal wedge. The left end of the super shows the wedge with its thin edge to the head of the screw, and in this position permits of the widening of the super by about  $\frac{3}{8}$  inch, for the easy insertion and removal of the sections. After they are all inserted, and the separators in their appropriate places, the wedge at the left side is turned other end to and driven down, bringing the thick end of the wedge against the screw-head. As the head of the screw is fixed, the wedge crowding against the head and against the super side, it causes the sections to be squeezed up compactly.

The interior view of the house-apiary shows just how these wedges are adjusted while the bees are storing honey in the supers. This method of tightening is quite ingenious, and I do not know that I have seen another just like it.

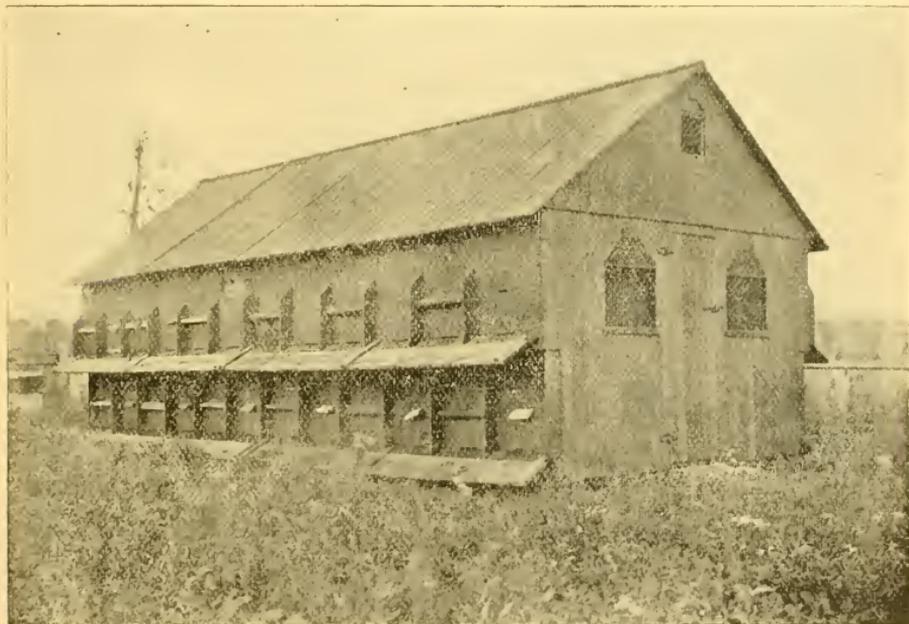

\* A full description of this is given in another column.

## MORTON'S PORTABLE HOUSE-APIARY.

While I was stopping at Mr. Morton's home I made a free use of the camera—taking shots at several of his ingenious "fixin's." On the day that I was at Groton there was to be another bee-keepers' picnic at Freeville, concerning which I will have something further to say at another time. It was arranged that Mr. Niver was to take the train, and Mr. Morton and I were to drive over to Freeville, stopping on the way to inspect one of his house-apiaries. Arriving at one of them I took a couple of views which speak for themselves. The building is made up of large panels, said panels being made at home, and so constructed that they can be put together and

windows with bee-escapes at the top as shown. Between the windows there is a doorway.

A unique feature of the construction is that there is a jog in the siding, as will be seen. The first tier of hives rests on the floor—see interior view. The second tier of hives rests on the jog or shelf, said shelf being exactly balanced, as it were, over the first section of the siding below. The object of this jog is to give the operator inside of the building plenty of room to work over the lower tier of colonies, without danger of bumping his head against the upper tier; then, while working over these latter, the operator stands upon the lower tier of hives. The jog will show both on the inside and outside. The arrange-

MORTON'S PORTABLE HOUSE-APIARY.

form a very neat and commodious house-apiary. By looking sharply at the half-tones you will see the dividing lines in the roof and in the floor. Any point that may be settled upon as being a good honey range may be selected as the site for the building; then if for any reason that locality in years to come does not prove to be as good a one as at first, the structure can be taken down panel by panel, piled on a wagon, and taken to some other point and erected.

The building is very cheaply constructed, single-walled, and made entirely of tongued and grooved boards. Close to each edge of the roof-boards is a groove, or gage, that conveys the water away from the cracks, thus making a roof at a very small expense, practically water-tight. At each end there are two large

ment seems to work very nicely, and adds but a trifle to the whole cost of the building.

## PARAFFINE PAPER FOR SECTIONS DEFENDED.

BY F. DANZENBAKER.

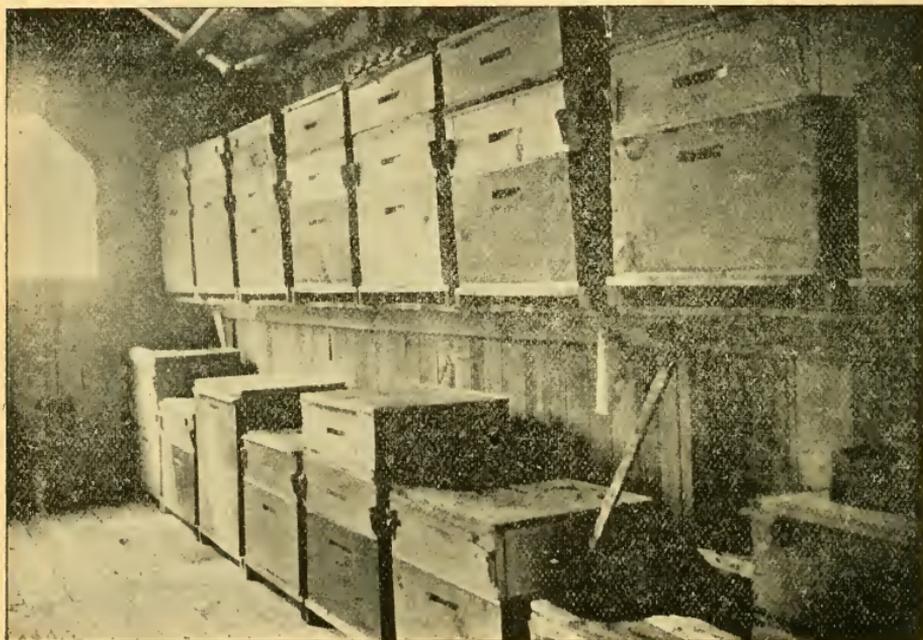

*Mr. Root:*—I notice the article of Mr. F. L. Thompson, page 734, from the *A. B. J.*, page 677, relating to paraffine paper for covering sections, etc., in which the writer shows to his satisfaction that he has not succeeded with it as well as he ought to or might have done, and decides he can get along without it. So far, well enough. Experience proves that bees daub and plaster propolis over enameled sheets, duck, burlap, etc., and cut through

them at their option. Any of these things cost in the first place. While bees at the close of the season may paste propolis at the juncture of the paper with the sections, to prevent wax-moths or worms from secreting themselves under the paper on the top of the sections, they do not paste on its surface between the sections as they do with the other fixings.

It was the comparative freedom from propolis when properly applied that has proved its value here on my own hives which, as there are no rabbets or open spaces requiring much gluing, may make some difference, for I have seen L. hives covered with enameled sheets, with tin rabbets stuck even full of propolis.

is more valuable, as we use new sections rather than clean up the old. However, I think it is nearer correct to say that the sections are *practically* free from propolis, or sufficiently so to justify the use of the paper in the time saved alone; of time cleaning sections where it is not used; but this is mentioned only as a compensation to offset the time taken to put it on. But it was not intended to be the *leading advantage*—only a secondary one.

The *chief* one was that it renders the supers air-tight at once, when properly placed, thus sparing thousands of bees to go afield that might be needed to keep up the necessary heat in the super without it. While saving other bees from gathering so much propolis before

MORTON'S PORTABLE HOUSE-APIARY—INTERIOR VIEW.

To-day I examined here my last supers taken off, and there was simply a line of pure wax at the juncture of the paper and edge of the sections. It could all be wiped off the entire super of sections with a piece of section, when they were ready to pack in cases, and the same set of mats had been used during April and May in North Carolina, then two weeks in Washington, and six weeks in Virginia. Many of them had been taken off and used seven and eight times, and are good yet. Heavier, tougher paper like flour-sacks, double coated, might be as strong and tough as enamel sheets, at one-third the cost.

But in using the lighter paper, single coated, at 2 cts., it is intended to use it but once or twice, so that it may be as well to tear it off and use clean sheets to clean it off when time

work could begin in the supers at all in a cold spell, it might save a week or more in the starting in the supers, and pay a hundred times its cost, even if a new sheet had to be used each time.

Washington, D. C., Oct. 31.

["It never rains but it pours." Perhaps friend Danzenbaker will think so when he reads the following editorial from the *Canadian Bee Journal* for November. Here is the item:

Our brethren (or, rather, *some* of our brethren) on the other side of the line have been advocating paraffine paper over the sections to prevent the bees from propolizing the sections. We do not hesitate to say that no bee-keeper, anxious to produce first-class honey in sections, and willing to master that business, should use such paper. In the first place, it is not necessary so far as propolizing is concerned; and in the

next, the best-filled sections can not be secured without a bee-space above the sections.

It is but fair to say that Mr. D. does produce some very fine honey, and some of his customers have secured some equally good, as I can personally testify. While I am an advocate of a bee-space over sections I would not say that first-class honey can not be produced by doing away with the space and using paraffine paper directly over and in contact with the sections. Mr. Miles Morton, who produces as fine honey as can be found in the world, uses an enamel cloth (the equivalent of paraffine paper), directly on the sections, and so do many others.—Ed.]

#### DRY LUMBER FOR HIVES.

Its Great Importance for Western States; Why Bees Can Not Gather as Much Honey from a Distance of Four Miles as from Two.

BY M. A. GILL.

*Mr. Editor:*—May I call the attention of some of the eastern manufacturers of bee-supplies to the fact that goods intended for use in the arid regions should be kiln-dried to the "last extremity," or else the saw-gauges should be set to make at least  $\frac{1}{8}$  inch extra in all bee-spaces, either of hive or super? For the last two seasons I have labored with our association to purchase their goods of your firm, having noticed, while inspecting the bees of the county, that, in most cases, the goods sent in here from your factory (through Barteldes, of Denver, I suppose) have stood the dry climate well, and that the bee-space, even in old hives, is about what it should be.

But both seasons the committee have decided to purchase where they could buy a little cheaper; and the consequence is we got a carload of supplies last spring that was manufactured from such green lumber that the bee-space has disappeared, or so nearly so that it is of no account.

I purchased for my own use 300 supers, and shall be compelled to get out strips and nail on top of all of them, for in some cases I find the sections stand flush with the top of super.

I for one want a  $\frac{1}{8}$  bee-space, as I use no cloth or quilt on top of the sections, believing that I can keep the sections cleanest without them. I also fasten my starters so the dovetailed corner of the section comes up, which prevents the bottom from unlocking if the combs are not built clear down and fastened to the bottom; but the plan proved the worse for me in connection with the above-named supers; for our bees here, after July 1st, gather a very tenacious propolis; and in prying off the covers, even in the hottest part of the day, it would lift open the tops of from one to five sections on nearly every super.

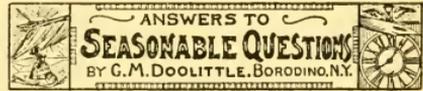

Imagine the bitter thoughts a man would have, when spoiling from five to ten dollars' worth of fine comb honey every day, and all for the lack of a proper space! No, the goods we got last season may be all right back east, but they are a dismal failure in a climate like this.

I see one of your subscribers from the windy Pacific coast asks if bees can gather as much honey four miles as they could two. May I ask him if he could carry as many sacks of flour home in a day four miles as he could two? Is a colony of bees much different from an industrious man in doing a day's work? Doesn't each do all it can, governed by conditions and circumstances?

Speaking of windy locations, I will say that, in my opinion, a high wind and a heavy honey-flow will prove very disastrous to the working force in a very few days' time if they have to fly a long distance. So if my bees, and the field where I expected them to work, were four or five miles apart, whether it was a windy location or not, I would hitch up my team and give the bees a ride of at least  $3\frac{1}{2}$  miles.

Grand Junction, Colo., Oct. 7.

[Thanks, friend G., for the fine compliment you pay us. We have made a sort of specialty of hives for the West, knowing full well that all the lumber must be thoroughly dried or else provision made for bee-spaces. We have endeavored to do both; then if the bee-space does shrink up to the desired point, or the point that suits one, he can with a jack-plane go around the top edge once or twice, and bring it down a trifle.—Ed.]

#### LATE-REARED QUEENS.

*Question.*—Will queens be of any use which are reared after all the drones are killed off in the fall?

*Answer.*—If all drones are killed before any queen becomes old enough to be fertilized, and the season of the year is late fall, of course such a queen will become barren, or a drone-layer. Some would say a drone-layer, every time; but my own experience has been that nearly or quite half of the queens which I have wintered over that were not fertilized never lay at all. But if I read the question aright, the asker wishes to know if a queen which fails to meet a drone before going into winter quarters will be of any use. Well, that depends upon the size of the colony she is in. If it is merely a nucleus, with no prospect of wintering over, then I should say such a queen would be worthless. But should the colony be a good one, then I should consider her of some value in such a colony, as my experience goes to prove that a colony having a queen, be she laying or otherwise, will remain much more quiet during the winter months than will a queenless colony; hence the colony having a queen will come out stronger in the spring, with less consumption of stores, than will one with no queen. This non-laying queen can be allowed to remain with the colony until we are able to procure a young

laying queen from the South, and thus a good colony may be saved which otherwise might be lost. Still, I consider it much more desirable to purchase a queen from the South and introduce her to the queenless colony, where such is possible, than to try to winter over either a queenless colony or one having a virgin queen. My reason for so doing is this: Such purchased queen will commence to lay during February or March, and from her brood the colony will be materially strengthened before a queen could be procured in the spring, and thus the colony becomes ready to take advantage of the early honey-flows in the spring, which would be of little use to the colony which went through with a virgin queen.

But there are some other thoughts brought to mind by the question, which it might be well to notice. How does any one know that all the drones are killed off in his section of country previous to October 15th or November 1st? I have been quite sure several times that there was not a drone within reach of my queens' flight, and yet the spring proved that every one of my late-reared queens had found drones from somewhere, as they were all prolific layers of worker-eggs. In fact, every time I have tried to winter over virgin queens by way of experiment, all but two proved to be fertile in the spring, only as I clipped their wings so it was impossible for them to fly out in search of any drone that might chance to be left. So I have ceased to worry over late queens failing to become fertile.

Another thought is, that no bee-keeper should try to rear queens late in the season unless he preserves several hundred drones from the very best stock they have in the yard or apiary. It is a very easy matter to keep choice drones, even as late as December 1st, by taking frames of drone brood from choice colonies just before drone-rearing ceases, and putting said brood in a colony from which you now remove the queen. Ten days after the queen is removed cut off all queen-cells, and such a colony will keep its drones as long as any are desirable in the fall. If a frame of sealed worker brood is given to this colony occasionally, its strength will be kept up so that the flight of drones will be more profuse late in the season than would be the case if the workers become few in numbers. Then if an upper story filled with combs of honey be placed on the colony which is to retain the drones, the drones will fly still stronger, for, to fly strongly, drones need plenty of honey within easy access.

If you do not think it too much trouble, drones can be made still more active by feeding the queenless colony containing them plenty of warmed syrup or honey at about noon in September, half past eleven during October, and at eleven o'clock in November, feeding only on such days as bees can fly. If, in addition to this, you go to this drone-keeping colony on some day during the latter part of September, when it is still and yet so cool that you will not be liable to be troubled with robber-bees, and carefully go over every frame in the hive, killing every drone that is at all

inferior as to size, marking, or in any other way, you will have something along the line of drones for your late-reared queens to mate with that will enhance the value of every colony of bees containing such queens from 25 to 50 per cent. This is what I have done several falls, and I think it has paid me fully as well as any work I ever did in the apiary. If we are to keep up with the times we must strive for the *best* bees as well as the *best* honey, put up in the most marketable shape.

#### KEEPING AND USING OLD COMBS.

*Question.*—A few weeks ago I lost a colony by starvation and worms. I burned some sulphur under the combs and killed the worms. Will the bees accept such combs next spring? They still smell of sulphur. What should I do with the hive of combs till I can use them next spring?

*Answer.*—First, let me say that the thought of losing any good colony of bees from "worms" is erroneous. The larvæ of the wax-moth get possession of the combs only when the colony of bees becomes so weak (or is gone entirely) that it can not properly cover the combs. If your colony starved, then the worms took possession after the bees were dead. The burning of sulphur, to kill the worms, was the proper thing to do. As far as the smell of sulphur on fumigated combs is concerned, I am of the opinion that it is agreeable to bees which can take possession of them afterward. At least, I have noticed that such combs, lately fumigated, will call robber-bees in crowds in much less time than will combs not so fumigated. But even if offensive just after fumigation, the smell of sulphur would all vanish long before you could use the combs in the spring.

There should be no difficulty in keeping combs from now till next May in any place, unless it be in the far South, where they might have to be looked after occasionally to see that worms did not get on them again.

A good way to keep combs is to hang them two or more inches apart in an airy room, after they have been fumigated; and if thus left they will take care of themselves till swarming time next year, in most parts of the United States and Canada. If they are to be kept a year or more, or over summer, they will need fumigating or freezing till we are sure there are no more moth-eggs to hatch, when they can be packed in any place which is proof against the female wax-moth, when they will keep for an indefinite period, provided the place where they are stored is kept fairly free from moisture. In great dampness they would take on mold, and become rotten.

#### THE FENCE: A SUGGESTION.

*Friend E. R. Root:*—When I sent you that sample hive last winter I thought you would get on to the idea of the cleated separator and no-bee-way (or nearly so) section. It is my opinion that the top and bottom bars of the sections should be a little narrower than the sides or uprights. I believe it would give a better finish at these points. However, you are on the right track, but be sure not to put all the bee-space in the separator, for if you do the cappings will frequently be broken along the edges by being attached to the separator cleat.

R. C. AIKIN.

Loveland, Colo., Nov. 4.

THOUSANDS OF TONS OF HONEY GOING TO WASTE IN SOUTH DAKOTA.

*Dear Friend Root:*—The greatest surprise of my life in the bee-line occurred the past season. I used to keep bees in Wisconsin, and in old Jersey, and know what they can and ought to do. When I came here and saw the flora and felt the high winds and the drouth, I concluded bees could not be kept except by feeding. One does not know unless he has tried. We may *think* we know all about a thing, and that is usually the time we are mistaken. It seems bees winter well here, both on summer stands and in cellars. The winter is usually broken up into extremes of warm and cold, with little snow, so that they can fly often. Given a good chaff hive like yours, and 25 or 30 lbs. goldenrod honey (the finest in the world, thick when gathered, and ready to seal at once), of which there is a great amount everywhere, and they will come through gloriously. The earth is usually dry, and a cyclone-cellar will winter the bees superbly. Well, a pair of two-frame nuclei, made July 1st, and furnished foundation as needed, gave a surplus in half-extracting-frames of 75 and 65 lbs., and have the 8 frames in brood-chamber full of honey, and are still working on mustard, and raising brood. I have a lot of mustard honey, and know of none better or finer flavored. It seems too bad to see thousands of tons of honey going to waste on these prairies when each farmer, by small investment, might have an abundance of nature's finest sweets.

STEPHEN J. HARMELING.

Marion, So. Dakota, Oct. 1.

QUEENS PIPING—HOW DO THEY DO IT? WHITE VS. YELLOW SWEET CLOVER.

In regard to queens' wings being instruments of piping, I would say emphatically that Dr. Miller is correct, for I had a queen several years ago that had not a vestige of a wing, and have seen her plainly when piping, and her piping was just as strong and vigorous as one with two perfect wings. There is a tremulous motion of the wings when piping, and you will see this same tremulous motion of the stub of the wings, or shoulders, the same as you see the tremulous motion of the flanks of a horse when neighing (if not of his tail), or the tremulous motion of the feathers of a hen when singing her morning song. From personal observation and "my" judgment, the tremulous motion of a queen's wings when piping is nothing more nor less than muscular vibration.

Replying to editorial, page 742, Oct. 15, I would say: Years ago, when I lived on a farm, there was a bunch of "white" sweet clover that grew under our east window. It grew

about three feet high, and branched out much like buckwheat, and it was white with blossoms the greater part of the summer, and was literally covered with bees from daylight till dark. Since leaving the farm I have not seen a stalk of the white, but have seen a number of bunches of the yellow here, *about two feet high*, in the village, and I have noticed them at all times of the day, and have never been able to see a bee on it, although there are plenty of them from five rods to half a mile distant. Whether it is variety or locality, I could not say, outside of my own experience, which is positively the former.

Hillsboro, Wis., Oct. 25.

ELIAS FOX.

[I am pretty near ready to give up. When two such men as you and Dr. Miller say I am wrong, I am half persuaded. A little incident happened the other day that quite converted me. Back of my desk I sometimes use sticky fly-paper to keep flies off my head, and I am not bald-headed either. One day I heard a loud sort of whining noise, and, looking down, I saw a fly on its back, wings stuck fast to the paper. Whining? Why, he fairly howled with his tiny voice, and it was perfectly evident that he made this noise, not with his wings, which were held immovable, but by means of a rapidly vibrating diaphragm, perhaps. After that I caught a bee, and was cruel enough to treat her in the same way; and, lo and behold, this bee piped when I poked her, helpless and supine on her back; but don't tell the doctor that I am converted to his way of thinking. It would afford him too much real pleasure.—Ed.]

GETTING BEES TO TAKE HONEY FROM SUPERS WITHOUT OTHER BEES GETTING IT.

As Dr. C. C. Miller wanted to know how to get bees to take honey from a super without other bees getting at it, I will say that, with us Iowans, by taking an uncapping-knife to uncap all that is capped, and cutting the top of the cells that are not capped, and putting an empty super below, the super that has the honey in it will work with us, but it may not with Illinois bees.

W. CARTWRIGHT.

Steamboat Rock, Ia., Oct. 20, 1897.

[Your plan sometimes works in Ohio, and sometimes it doesn't; and I suspect this is the case in Illinois.—Ed.]

GETTING HONEY OUT OF SUPERS WITHOUT ALLOWING THE BEES TO TOUCH IT.

*Mr. Root:*—I notice in the Oct. 15th GLEANINGS that Dr. Miller, in Stray Straws, wants a plan to get the honey out of a super without allowing other bees to touch it. That's easy enough. I'll tell you how I do it. When, in taking off supers at the close of the season, I find a colony that is short of stores, I leave the bee-escape on; then when I get ready to have unfinished sections cleaned up, I go to these colonies and remove the escapes from the boards, plugging up the holes with a block having a small hole in it. Then I tier up with unfinished sections or any combs I want cleaned. They are always cleaned out promptly if

put on at a time of scarcity when bees would rob.

CHALON FOWLS.

Oberlin, O., Oct. 22.

WINTERING SUCCESSFULLY UNDER SEALED COVERS.

I have good success wintering under sealed covers (boards one inch thick) in good chaff hives by placing 10 or 12 inches of buckwheat chaff over them. It should extend three or four inches on each edge of the sealed cover, and be put on before frost. Tell Dr. Miller if he will put his bottom starters on sections in a curve he will have less trouble by their falling over.

W. C. SIMONS.

Arlington, Pa.

*J. R., Cal.*—Without knowing more of the conditions it would be impossible for me to tell just why your bees leave the hive at this time of the year—October. If they have honey, brood, and eggs, the circumstance is very unusual. It might be well to investigate and see whether mice or other vermin have access to the hive. Sometimes bees will desert the hive because of this.

*D. N. R., Ohio.*—I omitted telling you how to get rid of the small worms that are on your honey. One way is to burn sulphur in a tight room where the honey is; and another way is to purchase about a dime's worth of bisulphide of carbon and let it stand in an open vessel, and evaporate; but some have said the bisulphide of carbon injures comb honey, and I would therefore advise you to use the sulphur instead.

*A. B. M., Fla.*—There are very few bee-keepers in the world who keep anywhere near 500 or 600 colonies, and perhaps two or three that keep as many as a thousand colonies, and perhaps only one man who keeps over that number. As a general rule, there are very few places indeed where it would pay to keep a thousand colonies, and I doubt very much whether it would pay you in Florida to go over 400 colonies, and then you would do well to proceed cautiously. Increase gradually by establishing out-apiaries one by one. It is possible you might be able to manage a thousand colonies; but I would advise you to "go slow."

*F. B. J., Ark.*—If you expect to move your bees half a mile some time this fall or winter I would advise you by all means to move them before cold weather comes on—the sooner the better. If the temperature outside is not over 60° Fahr. it will not be necessary to put wire-cloth screens over the tops of the hives, removing the covers. Simply nail wire cloth over the entrances, and load the bees into the wagon.

In regard to a place for swarms to cluster

upon next summer, in a yard where there are to be no trees, I would advise you to start some low-growing bushes, something that will grow rapidly, and at the same time will act as shade for the bees. The bees will very often cluster on these rather than go off to the woods or some tall tree.

*J. L. C., N. Y.*—The sample of brood has been examined, and I find it to be a very bad case of foul brood—one of the worst I have ever seen. You are probably familiar with the method of treatment. If not, refer to p. 34 of our catalog, last paragraph or two.

I can hardly think the queen you got of — could have transmitted the disease. I never knew a case yet where a queen from a diseased colony, when sent by mail in a mailing-cage, would transmit the disease to the colony receiving her. For experiment we have taken queens out of diseased colonies in our apiary, when we had foul brood some years ago, and introduced said queens into healthy colonies, but never any bad results followed. I should be more inclined to think the foul brood came from the colony you purchased in the first place, or else was already present in your vicinity.

*W. W. L., Pa.*—Yours of Oct. 21 is received, and I have carefully noted all you have said in your letter in reference to the accident to the span of horses by which they were stung to death by your bees as they were going to and fro to the buckwheat-field. First, I would say that you could probably get no help from either Bee-keepers' Union unless you were a member before the accident took place. If you were one, and have been right along, then of course I would lay the matter before one of the Unions at once—that is, to whichever one you happen to belong.

The case involves a good many legal points, and it looks as if, in view of the fact that you had previously warned the boy against driving his horses by at a certain time of day, telling him that there was *danger*, and he disregarded your instructions, the amount of damages, no doubt, would be very much smaller than it would otherwise be. It is possible that the court would decide that, under these circumstances, you were not under obligations to pay any damages whatever. In any case, I would advise you to employ as good an attorney as you can find, and get him to advise you in regard to legal points. If he decides that the case would probably go against you, then you had better settle without recourse to law. Get an attorney who would be *honest* with you, and one who is not hungry for a job; otherwise he may state that there is good fighting ground, and that you had better take the case before the courts, when you have actually "no case." In the mean time I would advise you to be careful about making any promises, or stating what you will or will not do. Just state that you do not care to discuss the matter until you can see your attorney, and yet I believe you mean to do what is fair and right. Later on I should be glad to hear the result of the case; and after the thing is all settled, write it up for these columns, telling how it was adjusted.

THIS journal seems to be nearly all editorial matter. We promise not to monopolize so much space next time.

THE last number of the *Bee-keepers' Review* is a good one. In spite of the fact that Bro. Hutchinson has "passed through the deep waters" so recently, he seems able to keep his journal up to its own excellent standard. Most men would be too nearly crushed to be able to do good and creditable work so soon. Bro. H.'s pluck and good sense in going right on with his work in spite of deep sorrows are to be admired. We hope our readers will remember him when they make up a list of papers they will take the coming year.

#### A POSSIBLE METHOD FOR CONTROLLING FERTILIZATION OF QUEENS.

MR. L. A. ASPINWALL, of Jackson, Mich., has black and hybrid bees all around him; but by clipping a small trifle off from the wings of each queen he has managed to have a much larger per cent purely mated. The idea seems to be that the queens have more difficulty in flying with their wings clipped down, and consequently the mating is restricted to a great extent to the drones around home. By this plan Mr. Aspinwall, according to the *Review*, "has kept the mated down to one in twelve with clipped queens, while the unclipped average one in four." It is not stated how much Mr. Aspinwall clips off to bring about this result, although mention is made of one queen from which an eighth of an inch had been taken from each wing.

This is valuable; and if equally good results shall be secured by others in a vicinity where blacks and hybrids are predominant, we may feel that we have "gone and done" what has hitherto been regarded as impossible.

#### A SAD ACCIDENT.

I AM pained to note, by the *Progressive Bee-keeper*, an accident that happened at the factory of the Leahy Mfg. Co. While Mr. Leahy was passing at some distance, a scream and a falling of lumber attracted his attention. Three children—two of them belonging to his partner, Mr. E. B. Gladish, had been trying to climb up on a lumber-pile, resulting in its falling "over on them, crushing the life out of one, while another had a leg broken, and Clifton Gladish was more or less injured. The one killed was little Florence Gladish, a bright sweet child of four years." GLEANINGS extends to Mr. Gladish its sincere sympathies; and while neither he nor any one else can really be blamed, it is one of those unfortunate things that sometimes will happen. I have always had great fear that my own boy, always eager to climb up on lumber-piles, might have something similar happen to him. The little tots scarcely realize that a lumber-

pile is almost as dangerous as a railroad-track, and yet it is well nigh impossible to keep eyes on them all the time.

#### FOUL BROOD IN SCHOHARIE CO., N. Y.

I SAID some little time ago that foul brood was making rapid headway in districts where there were more bees and bee-keepers than in most places in the United States, and I had in mind (though I didn't say so) Schoharie Co., N. Y. I am pleased to learn that, through the energetic efforts of the foul-brood inspector, Mr. Frank H. Boomhower, of that county, the disease is being rapidly stamped out; but he fears it is working over into adjoining counties that have just as many colonies of bees in them, but over which Mr. B. has no jurisdiction as inspector; and he hopes that I will put in a warning that bee-keepers in those vicinities may be alive and awake to the danger that may confront them next season. Mr. Boomhower says he has worked every day since he was appointed inspector, and that every yard so far inspected has been affected by it, and that in some instances whole yards are wiped out entirely by the dread destroyer. In one instance he found 51 colonies out of 61 that were rotten with the disease. I think it would be a good idea for the State of New York to have Mr. Boomhower appointed State Inspector. When I visited him early last fall I was much impressed with the thoroughness with which he did every thing he undertook. He thinks foul brood is an awful scourge, and that it should be handled promptly and energetically. And it is this kind of men that make good inspectors.

#### A BOOK ON PATENTS; THE SMASHING OF THE SECTION MONOPOLY.

J. A. OSBORNE & Co., have just issued a hand-book of patent law. We did the printing, and, of course, that part of the work is A No. 1. We are not up on patent law; but Mr. Weed, who is, says he believes this to be the very best hand-book of the kind of any thing heretofore published. It answers most of the questions usually asked by inventors, manufacturers, and patent-owners and users of patents, and further considers what is patentable, etc. A copy of this book can be obtained free on application to J. A. Osborne & Co., 580 Arcade, Cleveland, O. Some of our readers will remember J. A. Osborne in connection with M. D. Leggett, of Cleveland, one of the attorneys who helped to defend us in the suit brought by Forncrook in the famous Forncrook section case. It went through the lower courts, and then it went to the Supreme Court of the United States; and Judge Stanley Mathews declared the Forncrook patent "null and void for want of novelty." This, expressed in ordinary language, simply meant that the one-piece section, which formerly had been selling for seven, eight, and even ten dollars a thousand, was old, and therefore by this decision was made common property; and the result was that other manufacturers commenced making it, and the price finally dropped to \$5.00, then to \$4.00, then \$3.50, then to \$3.00, where it now stands.

THE VALUE OF VENEER STRIPS BETWEEN SECTIONS IN A SHIPPING-CASE.

In the *Canadian Bee Journal* for November, Mr. E. Kretschmer makes a point which I am sure is well taken. He says:

Separators in shipping-cases are, I think, not yet very much used; but I find that, if separators are used, a comb broken from a section, if confined to the space within that section, can not break or deface the next adjoining section; whereas, if the separators are not added, the entire row is frequently broken down. Wood separators are cheap, costing less than 2 cents for a case, while their benefit is more than tenfold. I therefore think that no shipping-case is complete without the separators.

Quite a number of the York Staters use thin veneering stuff between their sections and shipping-cases. In the case of the no-bee-way sections it will be not only a necessity but an advantage to use such veneering; with such sections, if the combs should break down they would have less distance to tumble against the separator, and the consequent damage to the comb would be less.

"GO WEST, YOUNG MAN;" JOE'S PARTNERSHIP.

SOME fifteen years ago a young man applied for a position as stenographer at our office. His letter was neatly written; and after some little correspondence the applicant came on. This was none other than Joseph Nysewander.

JOSEPH NYSEWANDER.

He filled the position in our office very creditably for two years, and then, taking Horace Greeley's advice of his own accord, left us to strike out for himself in the great West. He landed in Des Moines, Ia.; and after a little time his name appeared in the advertising departments of the bee-journals as supply dealer and manufacturer. His business kept on in-

creasing until last year, when, to my certain knowledge, he disposed of something like 13 carloads of goods.

The name of Joseph Nysewander and Root's goods have come to be almost inseparably

linked together. His place of business on Grand Avenue is shown in the annexed half-tone. On the left will be seen a wagonload of hive stuff just as it came from the car, direct from the Home of the Honey-bees.

Mr. Nysewander, besides doing a large business in the way of handling supplies, also sells considerable honey.

Now the romantic part of my story comes in. It seems Mr. Nysewander *also* had an application for a position as stenographer. I do not need to go into details; but it is enough to relate that Joe was a bashful bachelor, honest and good, and the stenographer was proficient and pretty. A life partnership was formed, of course, and the business boomed as it had never done before. No wonder he sells supplies.

COMB HONEY IN NO-BEE-WAY SECTIONS, VERSUS COMB HONEY IN OLD-STYLE SECTIONS WITH THE BEE-WAY.

ON page 715 I refer to the fact that no-bee-way sections with filled combs seemed to look plumper and nicer than the same comb honey in the old-style sections. To give our readers somewhat the actual difference in appearance I asked one of our men to select eight regulation 4¼ sections from our lot of comb honey. At that time we did not have very nice honey on hand; but he was able to select 8 sections that would average with No. 1 comb

honey as it generally runs on the market. These sections were to be as nearly alike as possible. From four out of the eight he was to plane off the bee-ways so that the sides of the sections would be of the same width as the tops, or straight all around. Next he was to put four of them in a shipping-case, and the other four, that he did *not* plane down, in another shipping-case. These were then placed one on top of the other, on a box, where I photographed them, and the result is shown in half-tone herewith.

Both cases of sections came from the same lot, and from the same man, and were as nearly alike as could be. In the upper lot you will notice that the comb honey comes nearly flush even with the sides of the sections, and almost up to the glass, but not quite. In the lower lot will be seen the regulation standard section, and it will be noticed that the comb honey stands back in, from  $\frac{1}{2}$  to  $\frac{3}{8}$  inch from the glass of the shipping-case, and to *my* eye, at least, they do not seem to

be as well filled out nor do they look as plump full and pretty as those in the top case. You will notice, also, that the fact that the combs stand back half an inch in the

can try the experiment with his own honey in his own shipping-cases.

But old-style sections planed down do not give quite the effect of comb honey produced in no-bee-way sections with slatted separators. When the bees go back and forth through the slats in the separators they have a tendency (if my eyes have not deceived me) to fill out the combs a little fuller; and they are also less inclined to leave a hole at each of the four corners. The very fact that, in one-piece sections of regular style, the opening, or bee-way,

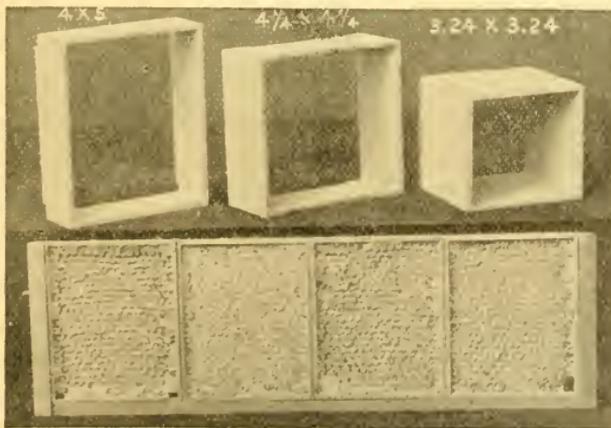

COMB HONEY IN NEW AND OLD STYLE SECTIONS.

comes up to within half an inch of the corner, causes the bees to make a hole generally in each of the corners; and that is one reason probably why some York State bee-keepers have preferred four-piece sections. The other reason is that they have bee-ways clear across so they can insert glass.

But another factor in preventing the bees from making holes through the corners of the sections is having the cross-cleats of the separators drop down  $\frac{1}{4}$  inch from the top of the section, so the bees have free passageway clear across the face of the sections,  $\frac{1}{4}$  inch from the top, besides a passageway through the slats from one section to another.

To show you how honey looks in 4x5 Danzy sections, with no bee-ways in front, and produced with cleated separators, I reproduce here a cut from Mr. Danzenbaker's book, "Facts About Bees." You will notice that the corners are all filled at the top, and nearly

COMB HONEY IN NO-BEE-WAY SECTIONS PRODUCED WITH THE FENCE.

lower case gives them a darker shade. The exact difference is not entirely shown in the picture; but, as I have already said, any one

here a cut from Mr. Danzenbaker's book, "Facts About Bees." You will notice that the corners are all filled at the top, and nearly

all at the bottom, and you will also notice, owing to the absence of bee-ways, that the sections have a plump nicely filled-out look, such as sections having insets do not have.

#### THE REVIEW ON THE NO-BEE-WAY SECTIONS.

Since writing the foregoing, the *Bee-keepers' Review* for October has come to hand, and in it I find an editorial that interests me greatly, particularly as it confirms almost every point that I have made in favor of the no-bee-way section.

#### SECTIONS WITHOUT BEE-SPACES; THE LATTER BEING FORMED BY THE SEPARATORS.

While on my way home from the fairs I passed one day at the hospitable and pleasant home of Mr. L. A. Aspinwall, of Jackson, the man who furnishes an article each month for the first page of the Review. In his back yard is an apiary that now numbers 50 colonies. During the past season it has furnished him about 3000 lbs. of as fine honey as I have ever seen. A portion of it was yet stacked up on the shelves of his honey-room. A more even or perfectly filled lot of sections it would be hard to find. Mr. Aspinwall has for several seasons used sections without bee-spaces, that is, they are the same width all the way around, the bee-spaces being furnished by metal sets on the tin separators. There are also openings cut in the separators just opposite the meeting-point of each pair of sections. This gives the bees a freer passageway through the super, and does much to lessen the pop-holes at the corners of the sections. The plump, full, smooth look of sections filled in this manner, without the one-fourth inch of wood standing up above the comb-surface, does much to add to the attractiveness of the sections. It is almost impossible now to sell the old-style of sections to Mr. Aspinwall's customers. This style of section also allows the use of a machine in cleaning off the propolis, by means of which it can be done very quickly and effectually. Mr. Aspinwall uses a super of the knock-down style, with thumb-screws at each end, whereby the sections can be pressed very closely together, and when the season is over these supers can be piled away in very little space; but I won't steal his thunder, as he has promised to illustrate and describe all these things in an early issue of the Review.

The wonder with me has been that so many of the supply-dealers and bee-journals have been so stupid all these years as not to see and know that a no-bee-way section is far superior to the regulation kind with insets at the top and bottom. Why, I almost feel myself like making Bro. Aspinwall a visit to see his honey, and to learn more about his experience with these sections. But as we are promised that he will tell us something about it in the *Review*, assisted by illustrations, we may all, to a certain extent, take a peep into his apiary. Bro. Hutchinson, I wish you would tell Bro. Aspinwall to hurry up with that article, and at the same time hurry up the *Review* that will contain it.

#### INVENTIONS WHICH ARE IN ADVANCE OF THE TIMES.

IN line with what A. I. R. said in last issue, page 782, the latest issue of *Electricity*, a weekly publication devoted to the science indicated by its name, relates how one Moses G. Farmer exhibited the first operative electric railroad at Dover, N. H., fifty years ago; and, even prior to that time by some twelve years, a Vermont blacksmith astonished the scientific world with the first attempt in that line; but, as the editor of *Electricity* very pertinently remarks, "he and Farmer were too far ahead of the time to make much impress upon it; but during the ten years that have elapsed

since the installation of the Richmond road and the Philadelphia meeting, the little horse-railroads, converted into electric systems, have become enormous concerns, carrying annually millions of passengers where they had been carrying hundreds."

With regard to the cleated separators and the no-bee-way section, it would appear that such men as Miles Morton, of Groton, N. Y.; the late B. Taylor, of Forestville, Minn.; Oliver Foster, of Grand Junction, Colo.; Mr. L. A. Aspinwall, of Jackson, Mich.; R. C. Aikin, Loveland, Colo., and K. P. Kidder, were ahead of the times, but times were not ready for them. I firmly believe, judging by the correspondence that has come in lately, since I began the agitation of these ideas, that the times are now ripe, and that this cleated separator and the no-bee-way section will go a long way toward crowding the old-style sections with awkward insets into the background. While it is true the A. I. Root Co. may have an "ax to grind," we propose by every fair and legitimate means to push into popularity these two things—not so much for the "filthy lucre" there may be in them, but because they are a real step forward, and, as I believe, will prove to be a real help to the mass of bee-keepers who depend upon bees to a greater or less extent for their bread and butter. While it is true that the pushing of these two things will give the A. I. Root Co. business in certain lines, it can not fail to help other supply-dealers just in proportion to the prominence they place upon these same things that are as free as water, can not be patented, and are old.

But the thought that we have been all these years without the benefit of these two things, when in point of fact we already had them, is almost *provoking*. For years A. I. R. said he would give a large sum of money for a well of soft water on his grounds. Perhaps the offer was larger because he was sure no such water could be found here in Medina, where the water is notoriously hard. But when, a year ago, a well-driller went a little deeper and cased off the upper vein of hard water, an unlimited amount of very soft water bubbled to the surface (with the help of an engine) as much as to say, "Good-morning! I have been waiting here for years for you to let me out and do you good. Why did you not punch a hole through my prison sooner?"

#### THE NO-BEE-WAY SECTION OLD.

QUITE by accident, as I was running over some of our back volumes I ran across an advertisement of G. B. Lewis, of Watertown, Wis., calling attention to the value of no-bee-way sections. This advertisement appears on page 102 for Feb., 1882—nearly sixteen years ago. Mr. Lewis calls attention briefly to the advantages of such a section; but why bee-keepers did not "catch on" then I can not say, unless it is that they did not know or appreciate the value of cleated separators by which alone such sections could be used. Many and many a time we have gone back to first principles in hive-construction; and it looks as if, in the case of the one-piece section at least, history were about to repeat itself.

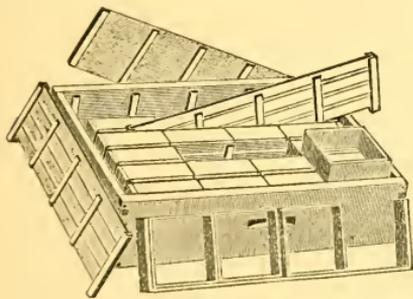

THE NEW SECTION WITH ITS FENCE; NOVELTIES FOR 1898.

The favorable reports that have come in from those who have been using the no-bee-way section and fence (cleated separator) for the last four or five years, together with words of indorsement from some of the greatest apicultural lights in the United States, have decided us to make the new devices regular for the coming season rather than to supply them on option as we at first proposed. Ordinarily it would be good business policy to feel our way by letting the new things push themselves

FENCE FOR SEPARATING SECTIONS.

into favor *gradually* rather than to get behind them and push them. Some of the reasons (to recapitulate) that have influenced us to make the fence and the no-bee-way section regular—that is, a part of the regular hive-equipments—are the following :

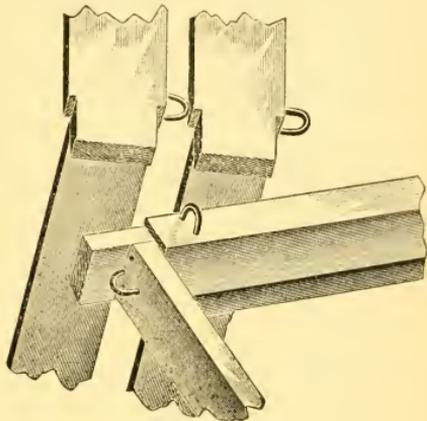

NO-BEE-WAY SECTION SUPER WITH FENCE.

1. The fences are made entirely of scrap, and, consequently, will cost but little more than the old-style separator, which, after being used a year, had to be discarded for a new one. As they will be glued together at the factory by automatic machinery, the bee-keeper will not be bothered to put them together. Those who have used this fence say it is good for years. They are, therefore, cheaper when viewed in this light than the old separators.

2. Prettier and better filled comb honey can be secured with a fence, for the reason that the bees can crawl all through the slats, affording them easy and direct passageways from one honey-box to another. *One great objection to the old-style super with its separators was that it shut off each section box into a compartment or room by itself*; and, as every one knows, it was much harder to get bees to

enter comb-honey supers than supers of the extracting sort. While we \* do not go so far as to say that the fence will offer as much inducement for the bees to enter the comb-honey supers as those for extracted, we do believe they afford most substantial encouragement; and for that reason we *believe* the bees will enter the supers a day or two earlier than they otherwise would.

STAPLED SPACED FRAMES.

3. The peculiar construction of the fence will, we believe, largely do away with the passage-holes in the corners of the ordinary section honey-boxes. I said, "We believe," for we are not positive; but after looking over lots of honey produced with the fence, and lots with the common separator, we notice the corner holes are much more prominent in the case of old-style sections that have been divided off with the ordinary separator.

4. The fact that the fence is made up of several different slats, bound by transverse strips on each side, and grooved cleats on each end, has a tendency to very materially stiffen and strengthen the section-holder. In case of the old-style super, the bottom-bar of the section-holder would sometimes sag; but the new fence is so much stiffer than the separator that we believe it will do away largely with the sagging of the bottom-bars.

5. The new section, when filled with honey, will bring a higher price, because they appear to be and in fact are better filled out, and the surfaces of the combs themselves are more even—at least this seems to be the experience of those who have used such sections with a cleated separator or fence; for instance, see what L. A. Aspinwall thinks in regard to this—a bee-keeper who has used them for years—in the extract from the *Bee-keepers' Review*, in the editorial department.

6. Facility in scraping these sections with their plain straight edges is quite an important feature. It is not an easy matter to clean out the insets of the ordinary old-style sec-

\* When I use the singular first person, I mean my opinion. When I use "we" I mean the opinion of our company.

tions, and practically impossible to remove the stain. A case-knife or a piece of steel having sharp square edges will, with one sweep, clean almost the whole four edges of the new section at once.

7. The new fence and section greatly simplify the construction of the section-holder. The bottom, instead of being scored out to correspond with the openings in the bottoms of the sections, is one straight piece and of the same width as the section itself. The end-bars are also of equal width with the bottom-bar.

8. The new section is only  $1\frac{1}{2}$  inches wide, and yet will hold as much honey as the old  $1\frac{3}{8}$  section with its openings; and consequently the ordinary shipping-case will hold from 15 to 25 per cent more honey, thus effecting a substantial saving in cases to the bee-keeper.

The new section-super with its fence and straight-edge section is shown in the engraving. The section-holder appears in the front with three sections. A fence appears at the end in the super itself. The follow-board is cleated the same as the fence; so also is one side of the super. With what I have already said, the general construction of the super will be plain.

#### NO-BEE-WAY TALL SECTIONS AND FENCE.

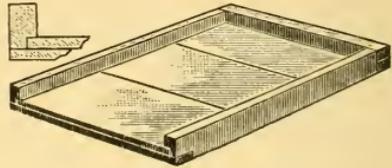

It is evident that there will be quite a demand for deep sections for the season of 1898; and we expect to be prepared to furnish the  $4 \times 5$  Danzy section with no bee-ways, and double-cleated separator, in the Danzy supers. The construction of the Danzy super is such that either the regular Danzy section with one bee-way, and separator cleated on *one* side only, or the  $4 \times 5$  sections no bee-way, and fence cleated on *both* sides. There are also some who would desire to use a deep section with no bee-ways, in their regular supers. We shall be prepared, also, to furnish a section-supporting rack—a device that will both support the sections and add to the depth of the super. These deep sections will be about the size of the Morton. They will be  $1\frac{1}{2}$  by  $3\frac{3}{4}$ . The super will be practically the same as Morton's shown in another column. Illustrations will appear in a later issue, that will show the plan.

#### NEW-STYLE DANZY BOTTOM-BOARD WITH ITS DEEP ENTRANCE.

I have already spoken of the advantage of having large entrances—so large, indeed, that it is not necessary for the bees to cluster out in front in order to keep cool on hot days. I have also shown that clustering out caused by contracted entrances on hot days has a tendency to induce swarming. I have also proved, to my own satisfaction at least, that a large entrance cures, to a very great extent, this clustering out, and will do away with at least 25 per cent of the swarms that now pester and bother us just when we want the bees to work in the supers.

The bottom-board that we have adopted for our regular hive-equipment for 1898 is the Danzy, and is shown herewith. We supplied this on option last season, and the results have

been so satisfactory that we have decided to make it regular for the coming year. It is so constructed that the bottom-board may be reversed. One side provides for an entrance  $\frac{3}{4}$

DANZY BOTTOM-BOARD.

inch deep, the whole width of the hive; and the other—the side shown to the observer— $\frac{7}{8}$  inch deep. The shallow entrance may be used during the robbing season. During hot weather, when honey is coming in, the deep side may be used. In the case of the old-style bottom-board, it had to be removed entirely for indoor wintering. But this is not true with the new one, for the deep side may be used next to the hive, and the hive carried into the cellar, bottom-board and all.\*

#### STAPLE SPACERS FOR THICK-TOP FRAMES.

I have long known that there was a certain class who do not exactly like the Hoffman frame. They seek something that separates a little more easily in the hive; and in localities where propolis is deposited to any considerable extent, a metal spacer may be preferable. When I stopped at Frank Boomhower's, Gallupville, N. Y., I found he was using staples as side spacers; and when I questioned him about it he said he had used almost every thing; but after having used these for several seasons he was simply delighted with them; and, what was more, his neighbors all around him were beginning to supply their apiaries with them.

For the season of 1898 we expect to equip all our thick-top loose suspended frames with staples. Each lot of 100 frames will contain a sufficient number to staple them as per the engraving. If the purchaser does not care to use spacers at all, he need not put them on. One staple is driven into the top-bar at each diagonally opposite corner. None are used in the end-bars, although they may be so used if desired; but for my part I prefer not to have them. As the heads of the spacers are rounding they admit of the frame sliding into position. The end staple used is the one shown last season, and has given universal satisfaction. We shall be prepared to furnish our customers, on option, this style of frame in preference to the Hoffman, when so ordered.

\* In relation to these points, I find that a writer in the *Progressive Bee-keeper*, speaking of a bottom-board with a deep entrance, says: "First, 90 per cent of robbing is done away with; 2d, with plenty of room under the frame and plenty of store-room at the proper time, swarming is done away with; 3d, bees never lie out on the outside of the hive with a large entrance; and, 4th, when bees can not reach the bottom of the brood-frame on entering the hive they are compelled to crawl up on the inside of the hive, instead of going up between the frames. Thus the supers are entered more readily. All this I claim for the large entrance and plenty of room under the bottom-bars of brood-frames."

ON THE WHEEL TO THE CELERY-FARM OF WEAN, HERR, WARNER & CO.

On Friday, the 29th of October, I visited the celery-farm of Wean, Herr, Warner & Co. Although the frost did them some damage, their celery had so far recovered that it seemed to my eye a sea of verdure and luxuriance. It was then all banked up for cold weather. All that was visible over the grounds was banked entirely with soil. The rows were, perhaps, five or six feet apart; and from the bottom of the ditch to the top of the rows of celery they must have been some three or four feet high. It was dug by means of a digger—a machine built specially for it. The hilling was also done almost entirely by machinery. Perhaps I should say at the outset that they have grown this year 140 acres of celery; and while everywhere else celery-farms have been greatly suffering from drouth, and many of them worse still by fire in the muck, our friends at Lodi have hardly felt the dry weather. In fact, their ditches, which were, I believe, 90 feet apart, are almost full of water at the present time. Why, it really looked as if it had been raining so as to fill the puddles and ditches at the side of the road. Mr. W. R. Wean informed me they were filled with the water from several springs along the base of the hills at the edge of the swamp.

Perhaps the most interesting object to me was their celery-washing machine. Imagine a great tub with the sides say three feet high, and may be twenty feet across. Inside of this tub is a revolving platform. The platform is either iron rods or very heavy poultry-netting. Of course, the platform is attached to an upright shaft in the center of the tub, and is kept revolving at just the right speed. The celery is spread out on this platform. At three or four different points there are appropriate iron pipes perforated with small holes so as to let a powerful spray strike the celery as it moves under the pipes. By means of a steam-engine and a steam-pump they keep a tremendous pressure on the sprinklers. One man at one side of this big tub pours the celery on the moving platform, and spreads it out. When half way around, another attendant turns it over. If it does not get fairly washed the first time, they let it go around again. Mr. Wean says when the washing is all done by spray the stalks are not bruised and rubbed as they are when a stiff brush is used or where it is washed by hand. You will notice how a root of celery turns yellow where it has been cut, say at its lower end, after it has stood several hours. Well, if the stalk is bruised or handled harshly it will become discolored and speckled throughout its length. The celery washed by the machine is of pearly whiteness, and will keep so several days longer than celery washed in any other way. The machine is the invention of Mr. Wean.

I rode down to the celery-farm on my wheel, with the northeast wind on my back, and it was fine "sailing," I assure you. Going back home, however, the wind was right in my face, and that was not so "fine." Now, here is a hint: When you are going out for a wheel-ride for any considerable distance, choose a day when the wind is at your back, and then you will be quite comfortable, no matter how hard the wind blows. If the wind does not turn around when you come home you will have to get back the best way you can—possibly on the cars.

By the way, I am told that, in some localities, their celery has not only been dried up by the drouth, but that the muck has got on fire, and in some places has burned out to a depth of several feet. Now, my impression is that these ashes would be worth quite a little as a fertilizer next season—at least on certain crops; but I have been told that in some places the ground is made almost worthless for celery or any other crop. Can any of the friends tell us whether this is true?

These people raise onions as well as celery, and it was my pleasure to look over the crop of 70,000 bushels nicely housed in the long rows of onion-buildings. Last year they got a dollar a bushel for their best onions; and with higher prices on potatoes, wheat, and other things, they think their chances good for something like it this year. And, by the way, I learned one new thing about keeping onions. In every lot of onions there are more or less that will sprout in spite of any thing that can be done. These are sorted out and thrown away. Of course, where the quantity is small they can be planted out for bunch onions under glass or in the open air in the spring; but out of a crop of 70,000 bushels the culls or bad onions would be altogether too great in quantity to utilize in this way unless somebody should make a special business of it and supply a special market in some very large city.

---

## OUR HOMES.

---

And thou shalt teach them diligently unto thy children, and shalt talk of them when thou sittest in thy house, and when thou walkest by the way, and when thou liest down, and when thou risest up.—DEUT. 6:7, 8.

If our readers will look up this whole 6th chapter of Deuteronomy they will notice that Moses has been exhorting the people to this effect: "Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy might." Then he goes further and gives the words of our text. And we also notice that he goes *still* further, and says, "Thou shalt bind them for a sign upon thy hand, and they shall be as frontlets between thine eyes."

In the *Rural New-Yorker* for Oct. 30 the editor submits a question to his readers, and below the question he publishes the replies from several different persons. Here are the questions:

## BREEDING OUT THE TOBACCO HABIT.

## THE BOY AND THE PIPE; TOBACCO AND THE BOY.

What, in your opinion, is the best way to prevent a growing boy or young man from using tobacco? Would you try to induce abstinence by a rigid prohibition, enforced by punishment, or would you endeavor, from earliest years, to create a distaste for tobacco by explaining its physiological danger to growing youth? In a great many cities, the dangerous effects of narcotics and stimulants are explained in the physiological text-books used in the public schools; yet, in the same cities it is found necessary to pass an anti-cigarette ordinance. What stand would you take in the matter?

I confess I was somewhat surprised to see this subject so boldly taken in hand by an agricultural paper. Other agricultural papers have at different times given us some excellent editorials on the matter of tobacco; but yet the most of them, I am grieved to say, either in the same issue or sooner or later, discuss tobacco culture, and publish articles telling how to manage the plant and the crop, without thinking they have done anything wrong or out of the way, evidently. This thing has jarred on my sense of right and wrong until I have felt as if I could stand it no longer. Another thing that has jarred *still worse* is that our government has been and is sending out bulletins in regard to the cultivation, gathering, and marketing the crop, without ever a word in regard to its effect on our people. I have eagerly caught hold of the bulletins, and scanned them from beginning to end to see if the learned professor belonging to the agricultural college whence the bulletin seems to have emanated did not somewhere touch upon the effect and the result of encouraging the tobacco industry. Not a word. There is nothing in the whole bulletin—nothing in *any* bulletin I have ever got hold of that seemed to intimate that the man had any sense of right and wrong at all. Perhaps he might say it was not in his province or department to discuss the matter. Now, our bulletins on growing strawberries usually have something to say in regard to the advantage that would accrue to our people, especially the children, if fresh berries were furnished to each family—all they could consume. Why, it is a part of the *government work* to discuss foods and their effects on the health. In fact, I have rejoiced to find of late that we are having quite a good many bulletins telling us how to cook food with economy, and as an aid to good health. Will not these same men—at least some of them—after a while get around to discussing the probable effect of tobacco and cigarettes on the comfort and future welfare of our growing population—especially their effect on the boys? And now, dear friends, perhaps you had better read that question from the *Rural* again, since I have had so much else to say. I have space here to give just one of the replies. It comes from a mother, and it comes nearer to my heart and home because she is an *Ohio* mother:

## CREATING THE DEMAND.

My four children were left fatherless six years ago. Two were boys, one of whom is now 17, and the other 19 years of age. Within the past year the eldest has taken to smoking an occasional cigar. The boys have been warned against the evils of tobacco from their

earliest youth. I did not have occasion to punish them then, as they did not use tobacco in any form. I always read to them, or got them to read for themselves, all of the deaths or calamities caused by cigarette-smoking, of which there are so many accounts in the daily papers. But they do not give them a second thought, as they know of boys of their own ages who use the cigarettes constantly, with apparently no evil effects.

The different tobacco firms use every inducement to get young boys for customers. A letter came this week to my eldest son, saying that his name was furnished by the merchant of this place, wanting him to try their particular brand. They also inclosed a coupon, good for one plug of their tobacco, which he was to get free from his dealer, who sent his name. The dealer then would return them the coupon, for which he would receive 10 cents. A laudable enterprise, wasn't it for a general dealer in a small country village? The letter and coupon were taken to the "store" by a very indignant woman, a few questions asked, and a few remarks made. I venture to say that the boy will receive no more coupons from that source.

FANNY FLETCHER.

I am making a good many extracts from the *Rural* in this issue, I know, but I want to give just another one, an editorial, where they comment on this mother's reply. Here it is:

What do you think of that storekeeper, who sent the names of boys to the wholesale dealers in tobacco that samples of their wares might be sent the boys? What would you do were it *your* boy? Wouldn't you make some "remarks" to such a dealer? Isn't it about the most contemptible piece of business of which you can conceive? Every decent man or woman with any regard for the well-being of the children of himself or his neighbors should not stop at making remarks, but instantly withdraw his custom from such a disgrace to humanity; this is the only effective way of reaching some dealers. This custom of furnishing names for various purposes is all too common, and they are often furnished for much more degrading purposes than that mentioned. Kill the whole business. In this city—perhaps in others, also—a postoffice box must not be rented to a minor, that much of this sort of thing may be guarded against. The writer was once in a country store in a little town in Michigan. In this store, tobacco was not sold, and signs prohibiting smoking were displayed. And what a contrast between that store and another in the same place where there was no such prohibition! It wouldn't be difficult to say where the best class of customers would go. Encourage the store-keeper with a conscience, and put both feet on the other disreputable or heedless character.

It is several days since I read these things in the *Rural*. I purposely waited, to see if I could find more about this business; and I have tried, too, to look on both sides of the subject. I know it is a fashion nowadays to furnish free samples of goods. Dan White, in our last issue, when he got on to the scheme of giving away samples of his nice honey, had evidently fallen into line with the modern way of doing business. Perhaps we can not really blame the tobacco-dealer for wanting to do what other people do, especially when the greater part of the agricultural papers, and even the government of the United States, discuss tobacco-growing as if it were just as praiseworthy as growing strawberries.

Who, then, is to blame? Why, we are *all* to blame. The daily papers are giving us continually the results of the tobacco and cigarette habit—especially the latter. They do not hesitate to speak right out plainly, and tell what killed the boy, and protest against the whole business. The doctors, the greater part of them, are bold enough to say frankly what the effect of cigarettes is on our boys; but when it comes to banishing or killing out the whole business, government officers and

business men seem strangely silent or stupid. They are afraid to say or do any thing, because there is "big money" in it.

I do not know but the people who sell them might give some sort of flimsy excuse, to the effect that a moderate use of them by grown-up people would not do very much harm—forgetting that practically nobody learns to use tobacco after he is of age, but before, when it is illegal to sell to him. This woman would have replied, however, to such an excuse, if it had been presented to her, that the cigarette habit is worse than tobacco or even the liquor habit, in that it can not be controlled to what some people might call "moderation." And even if the vender did refuse to sell to minors, one big boy could purchase enough to supply the whole school;\* and I am told that our school scholars are getting them and using them quite freely. Every teacher knows the effect of cigarettes on his pupils—not only on the physical health, but on the mind, which begins to be affected by even a small amount of tobacco. Boys are going to the insane-asylum, and dying in almost every neighborhood, on account of cigarettes. A death has recently occurred among my own relatives, and another is likely to follow soon.

Some may say, "If you do not like cigarettes, let them alone." But the vender is getting the addresses of schoolchildren, and mailing them letters or circulars, with a promise of something for nothing. Boys are curious about the effect of cigarettes, just as they are curious about electricity and other wonderful things that they have seen. Children are folding up make-believe cigarettes in order to have some fun when some one begins to scold and make a fuss. Trifling with any thing which is so dangerous, frightens and alarms me.

One of the writers in this same *Rural* intimates that the best of parents can not always control this thing. They say one boy will grow up steady and temperate while his brother is just the opposite. This may be true to some extent; but I can not help believing that the father and mother can make sure that their boys will never be addicted to these things if they care enough about it. Long before cigarettes were invented, and long before I became a Christian, I was satisfied that tobacco was a stepping stone to the liquor habit. Both Ernest and Huber commenced remonstrating with people about the use of tobacco almost as soon as they could talk plainly. I had to check them in order that they might not commence on entire strangers on the street in regard to the matter. They had probably heard it discussed so much by their father and mother that they grew up with an aversion to it. I know that, as the years pass by, they bring great changes; but

I can not believe that any change can come to pass that will induce either of our boys to use tobacco. I am not boasting of our own children, dear friends—I am only insisting that, if sufficient pains be taken, the matter can be managed.

Where will all this thing end if we do not take pains? I see little notices in the dailies, to the effect that the girls in some cities are forming clubs where they smoke cigarettes. I do not think this thing will go very far, however, for public opinion—at least the opinion of the intelligent and educated public—will be so strongly against it that a woman will not dare to bear the scorn and disgust that will come from the public at large. I admit that the cigarette business has been given some severe checks; and several times I have thought it was going to be stamped out; but yet in almost every community there can be found some man or boy who says by his actions, if not by his words, "It is nothing to me whether cigarettes kill or cure people. As long as they want them, and there is money in the traffic, I am going to sell them." The laws are helping us some; but, oh dear me! why don't they wake up? The adulteration of food is an outrage on the community, especially when something really baneful is put in it that is supposed to be pure food. But how about feeding our people opium under some sort of disguise, because the vender knows, when they get about so far along, they will have it any way, no matter what it costs? If this meets the eye of any of the professors who have charge of our experiment stations and the bulletins emanating therefrom, I should like to have them answer me; and if anybody sees it who has to do with the Agricultural Department at Washington, I wish such party would tell me what they mean by putting out a bulletin on tobacco culture, without any intimation as to whether or not it is a good thing to furnish our people a terribly baneful and poisonous article.

A man was once announced to speak at a farmers' institute in defense of tobacco-growing. He was a pretty good sort of man, except that he was largely engaged in growing tobacco. He stood before the audience for a brief period, looked very red in the face, and then said he did not think he had any thing to say in defence of tobacco, after all. I suppose he discovered that, instead of having an audience of tobacco growers and users, he was confronted by a lot of Christian people.

Now, I have not said very much directly in regard to our text; but I have had this in mind: That nothing in the world can do so much to keep our boys honest and pure and clean as to bring them up in the fear of the Lord. Let them listen to Bible-reading and prayer, and that from the lips of the father and mother, every day of their lives. Let the Bible teachings also be made so plain that they will see the bearing, and its practical application on every event of their lives. Do this, and walk consistently yourself, and I have no fear that the children will ever consent to take even a start in using tobacco or strong drink.

\* Since writing the above, an attorney in our employ tells me that one evening, while standing on the street near the postoffice his attention was attracted by a group of small boys, evidently waiting for and expecting something or somebody. Pretty soon a larger boy approached, opened a package, and distributed among the small boys what he afterward found to be cigarettes.

One word more in regard to our agricultural journals. When I call attention to such inconsistencies as I have in the former part of this article, I have been told several editors are employed on a journal, and they do not always think alike on these things. This will do very well when applied to matters that do not very greatly affect the health, and influence the morals of our people. But when it comes to the matter of encouraging or discouraging the tobacco industry, I should say the editors had better get together, and decide before they start out with the new year, what their journal is going to have to say about tobacco and cigarettes. Surely an agricultural paper can take as bold and decisive a stand as our dailies, that sometimes claim they are obliged to publish every thing—good, bad, and indifferent—because people demand it. May God be praised that we have editors who are not afraid to teach righteousness, purity, and temperance; and, after having so taught, are consistent enough to hold fast to their standard year in and year out.

I have had considerable to say in regard to our periodicals and journals. Everybody expects that, as a matter of course, the *church of God* will stand firm and unwavering in such a matter as this. But I am reminded just now that superintendents of Sunday-schools are often engaged in the sale of tobacco. We have here in Medina, however, one superintendent who banished tobacco from his grocery at the very time he became a Christian. In doing so he banished so many of his old customers that he felt at the time really troubled about it. This was years ago. At the present time I think all will admit he is doing the largest business, and has the finest store of the kind here in the village.

SOME THOUGHTS SUGGESTED BY READING "OUR NEIGHBORS" IN GLEANINGS FOR OCT. 1.

Mr. Root.—Bro. Vincent, of Milan, where I am supplying, handed me a copy of GLEANINGS for Oct. 1st. I was so pleased with *Our Neighbors* that I read it at home to my people, who declared it beautiful. These sermons must do good. I want you to send me a copy of that number, that I may forward it to a friend who will, I am sure, prize it. If you will, let me pay you for the number in the form of a little poem I have just written, and which you may place in GLEANINGS if you think it worthy.

May God bless all workers who seek to comfort, convert, and elevate. J. POLLOCK HUTCHINSON.  
702 Church St., Ann Arbor, Mich., Oct. 18.

PROVIDENTIAL GUIDANCE.

Open the way for me, O Lord, I pray;  
Open the way.  
Let there be light that I may plainly see,  
And faithful prove where thou wouldst have me be.  
I have my spindle and my distaff, Lord;  
Thy help afford.  
Let not the labors of my hand relax,  
But let me spin for thee; send thou the flax.  
Here is my harp; I can not play a right  
To give delight;  
Lord, tune the strings; then draw forth music, such  
As ne'er responded to musician's touch.  
Here is my heart; it, too, is out of tune;  
But thou canst soon,  
And thou alone, put it in perfect chord,  
And life be made an anthem to the Lord.

The concluding stanza of the above poem came home to me. I should be almost afraid to have the dear friends who read GLEANINGS know how often this poor heart of mine is

"out of tune." But, praised be the Lord, I have found a remedy. My little prayer, "Lord, help," very soon puts me right. And this suggests a beautiful thought I got from Rev. A. T. Reed. He invited me to speak one rainy evening, at Gustavus, Trumbull Co., O. At the close of my talk he asked for brief testimonials from the congregation. A great part of them arose, one after another, and testified to the power of Christ Jesus. Before he invited them, however, he said something like this:

"Dear Christian friends, please do not make the mistake of holding back just because you do not *feel* like it. Feeling has nothing to do with it. It is Satan's plan, to keep you still. Why, look here. Some morning Johnnie comes downstairs; and when his mother says, in a bright, cheerful tone, 'Good-morning, Johnnie,' he keeps perfectly mum, and does not answer her kind greeting at all. What do you think of Johnnie, even if he does give as a reason for his proceeding that he does not 'feel like it'?"

Johnnie knows very well what he *ought* to do, whether he feels like it or not; and the very best way in the world to get into a cheerful mood is to answer pleasantly and good-naturedly his mother's morning greeting. If he keeps still because he *feels* surly and cross, the chances are that he will be surly and cross all day, or, as our good brother has happily expressed it in the little poem, he will be "out of tune" all day. Now, shall we not all learn a lesson from Johnnie? Let us be pleasant and courteous and kind when we get up in the morning, because it is our duty so to do, especially when we profess before the world to be followers of Christ Jesus. Our feelings really have nothing to do with it; and, in fact, if we behaved ourselves in a Christianlike manner only when we *felt* like it, we should be the very poor Christians indeed. You know the old hymn,

"Am I a soldier of the cross," etc.

## Health Notes.

HEALTH WITHOUT MEDICINE.

Dear Bro. Root.—About twelve months ago you wrote some articles in GLEANINGS about "Health without Drugs;" and after telling your readers of the Salisbury water cure you immediately mentioned a book entitled "The True Science of Living," by Dr. Dewey. Feeling impressed that that book was worth getting I sent to America for it, and, having read it, I decided to give the method a three-months' trial.

I may state that I am forty-six years of age, and have been in the ministry twenty-two years.

When a lad I was not very robust; and from the age of eighteen up to within a year ago I suffered from dyspepsia, having some intervals of rest from dyspeptic troubles during this period. During the whole of those twenty-seven years I was not able to travel with comfort in the train, tram-cars, or back seat of a buggy, being invariably sick; and on the sea I was completely prostrated.

Aug. 29, last year, having read Dr. Dewey's book, I started the no-breakfast plan. That was on Saturday. On the following day, Sunday, I traveled twenty-two miles, preached three times, administered the sacrament of the Lord's Supper, and finished the day's work with a sense of ease and pleasure. I never threw more energy into my preaching up to that time than I did that day.

From the day I started this plan up to the present I

have had a clear brain, and have been able to think and study without any feeling of heaviness or fatigue whatever. Prior to this I used to feel the need occasionally of an after-dinner nap on account of a dull heavy feeling I had at mid-day. Since beginning the two-meal-a-day method I have not felt the need of such.

For the first six weeks or two months I lost flesh and weight, and became somewhat weak in body, yet always clear in mind. After that I soon regained flesh and weight and strength, and have continued in the enjoyment of good health ever since.

The result, after a year's trial, summed up in a few words, is this: Dyspepsia completely gone; ability to eat and digest any thing the appetite calls for; clearness of mind all through; greater energy in preaching than ever before, with no supervening tiredness on Monday; ability to travel with pleasure by train, tram-car, or buggy. (I have not tested it on the sea yet.) The no-breakfast method has been to me good, all good, and only good, and good altogether.

I hope that others may be led to procure the book and read it, and realize like benefits.

Murrurundi, N. S. W., Aus. GEO. A. REEVE.

Dear Bro. R., I thank you for your kind words, and I greatly rejoice that you have found such wonderful help and strength from so simple a remedy. But please pardon me if I suggest that it may not work as well with everybody as it does with yourself; and may I suggest, also, that perhaps a great many of our troubles arise from our eating more than Nature really demands. In any case, omitting the breakfast and cutting off the surplus gave Nature the chance she wanted; and I have several times suggested to Dr. Lewis that *one* of the reasons, certainly, why the beef diet gave such good results was that it entirely removes the trouble of overloading the digestive apparatus; and it also cuts off the harmful fashion of eating sweets and other things between meals. And now a word to our readers:

Dear brothers and sisters, when you smile at the enthusiasm of our good friend away off in Australia, please consider what a wonderful advertisement his letter would have been if he had secured the above result by using some *patent medicine*. May God be praised for the fact that he is not booming or advertising any kind of "doctor stuff." It would hardly do to suggest that his wonderful recovery was through enthusiasm awakened by that book; but it does teach with exceeding plainness that a very little thing may make all the difference between exuberant health and a painful malady. I have heard of great relief being obtained by simply cutting off tea and coffee, and drinking absolutely nothing at mealtimes. Others have found relief by eating dry bread or zwieback; and just now in a neighboring town I am told of wonderful cures that have been brought about by a cereal food cooked four or five hours in a double hot-water kettle. So many people got strong and well on this new health food that the proprietor has been receiving *five dollars* for his kettle and five pounds of the cereal food; and each purchaser was required to sign a contract not to divulge the secret of the method of cooking to any of his friends or neighbors. You may say that, if people get well, the money is well invested; and some of you have even gone so far as to say the same in regard to Electropoise—that, if a man or woman *got well*, the \$25.00 was well invested; no matter, either, if it was all through the influence of the imagination.

May God help us in our efforts to sift out the wheat when there is so *much* chaff.

Perhaps I should add, in closing, that the book mentioned above can be procured of the Henry Bill Publishing Co., Norwicht, Ct. Price \$2.25.

#### NO KILLING FROST BEFORE NOV. 6.

When we had quite a little frost on the evening of Oct. 7 I began to think this was a bad season for tomatoes, cucumbers, and perishable stuff; but after the tomatoes on the up-land began to show that they were not hurt very much after all, I told the boys to take care of them and may be we should have some tomatoes after all. Sure enough, we got our largest picking *after* that first frost. Before the frost, the tomatoes had brought a dollar a bushel; but along about the last of October they became so plentiful everywhere that the price went down to 40 cts. We were actually picking and selling tomatoes until Nov. 6. I have known this to happen so many times before that I rather expected it. Do not be in haste to think your chance is over for the season.

During the past two months we have had a severe drouth. In fact, the wells were dry to such an extent that farmers were coming in from the country to get water from our artesian well; and on my wheelrids I saw men, women, and children carrying water, almost everywhere, until Nov. 1, when we were greatly rejoiced by several days of rain. The sun then came out a little; then it rained again, and now, Nov. 10, every thing is rejoicing. I was just thinking this afternoon that such a condition of affairs would be sure to produce mushrooms; and while I write, a quart strawberry-box heaping full has just been placed on my table.

#### SWEET CLOVER, AGAIN.

We clip the following from a valued agricultural journal:

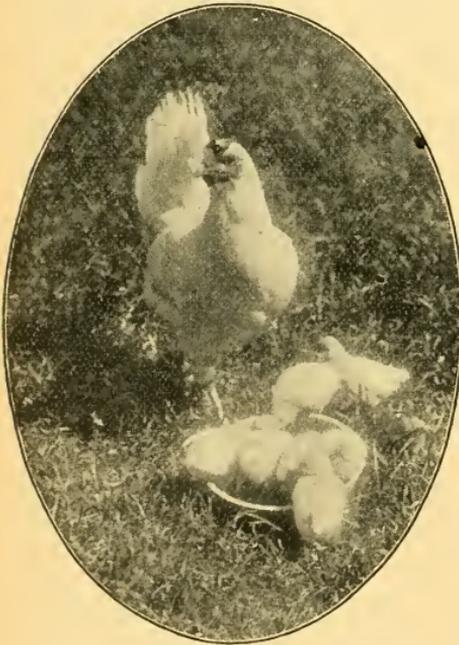

One kind of clover is a nuisance in farming, as, despite its savory name, it has no feeding value whatever. That is the common sweet clover which springs up beside railroad-tracks and other waste places. Cows will not eat it, even when it is young and tender. Bees sometimes visit its flowers, but the honey made from them is greatly inferior to that from white clover.

It seems to me the above is a series of mistakes. First, that it has no feeding value whatever, is surely not true; second, that cows will not eat it, even when it is young and tender. I should like to see such a cow. I have seen cows hunting greedily for it in almost every locality where I have traveled. It is possible, however, that there may be cows like those I found in Florida, that would not eat corn because they did not know what it was for. Once more: In my estimation, and in the estimation of thousands of people, the honey is little if any inferior to that from white clo-

ver. I suppose the locality and season may have something to do with it; but wherever I have found large areas of sweet clover, so that the honey was unmistakably from that source, both comb and extracted honey have been beautiful in appearance, and so luscious to the taste that I have called it equal to any made anywhere. Possibly a sample of sweet-clover honey not fully ripened might be disagreeable.

MY CHICKEN STORY; ALSO SOMETHING ABOUT LIFE-LIKE PHOTOGRAPHS, ETC.

One of the pleasantest features of that bright home paper, the *Rural New-Yorker*, is its beautiful and instructive cuts of rural life. It is not altogether the excellent quality of the cuts, but it is the happy selection of subjects and the artistic way in which they are presented; and when we consider that this high-toned family paper is sent once a week

A YOUTHFUL HEN MOTHER.

for only a dollar a year, it seems too bad that a single family in our land should be deprived of its beneficial influence. One of its happiest efforts in a recent number is a picture of a White Leghorn pullet that commenced to lay when she was 4 months and 16 days old; and at the age of 5 months and 21 days she was the mother of a brood of chickens. I have borrowed the cut; and if our printers bring it out in good shape I hope it will give you a thrill of surprise and pleasure as it did myself when I first saw it. See above cut.

We clip the following from the *Rural* as descriptive:

While we are discussing remarkable families of human beings in their relation to agriculture, let us not

forget the good hen. In the cut is shown a young hen or pullet which will, probably, take the record for youthful productiveness. This hen is a White Leghorn, bred and owned by O. W. Mapes, the electric hen-man. Mr. Mapes tells the following story regarding this "precocious pullet." If any of our readers have hens that can beat this record, we shall be pleased to give them an opportunity to exploit their pets in our columns.

"This pullet was hatched March 6, with 11 others. They were raised in a small brooder in the woodshed, and about April 15 they were carried to the middle of a three-acre field to keep them away from the back door, as they were very tame. Here they ran with a flock of about 500 younger ones, all eating from one long trough which was filled with feed as soon as possible after the chicks cleaned it, usually two or three times a day. In June she and her ten mates, in company with fifty of the later chicks, were colonized in No. 2 of my small poultry-houses. The surrounding houses were filled with the other younger chicks. There were no old hens nearer than No. 6—about thirty rods away. The pullets laid two eggs in No. 2 July 22, and continued to gain up to August 10, when they laid eight eggs inside the house. About August 15 I found this pullet in an old box in the rear of No. 2, sitting on fifteen pullets' eggs. The soft side of a board was the only nesting-material in use when I found her. I took pity on her and gave her some machine-shavings at once. She must have been one of the first to commence laying, as on August 27 she hatched out eight as bright-eyed chicks as I ever saw, of which she is justly proud, as her picture plainly shows. The feed has always been the same since the day she was hatched, except that a little baking-powder was added the first few days, and then the dough baked into a sort of balanced-ration bread; otherwise the feed has simply been wet with cold water."

Perhaps one reason why I like to look again and again at that picture is that, in my boyhood days, my first craze was for poultry. I sent off and bought a setting of eggs, and I was on hand, you may be sure, when the first chicken hatched. I was in such a hurry to feed them to see them eat, that, hadn't my good mother cautioned me, I might have done them harm; and then I watched their development day by day. I saw every new white feather as soon as it started. Like little pearls they seemed to me; and when the chicks grew older they were so tame I could pick them up at any time and anywhere, and exhibit them to admiring visitors. When the pullets were old enough to lay, with their beautiful red combs and bright eyes, it seemed to me as if the whole face of animated creation presented nothing equal to them. I used to carry them up to the house and show them to mother every few days, with an exclamation something like this: "There, mother! just look at her! and only five months old! *isn't* she a beauty?" When they began to lay it was a question who was the happier—the pullets or their youthful owner.

I remember of having a half-barrel fixed with a faucet so the water would drip just as fast as my biddies would catch it as it trickled down. Then I had the rain water from the roof of my poultry-house run into this barrel, so you see the thing was sort o' automatic. One day when I was at school something in the rain water got into the faucet and stopped the flow of water. It was a hot day, and the biddies, not being able to catch even a drop from their accustomed faucet, began to make investigations, and climb on top of the barrel. They tilted the boards that had been laid on top, boy fashion, and then jumped in to get a drink. When I got home from school, three or four of my precious laying pullets were

stiff and cold in the water-barrel. Oh! but wasn't there sobbing and lamenting? As I looked them over and tried to make them stand on their feet as they did in life, it seemed to me I could *not* have it so; and I remember of telling mother that I should have to stay out of school to keep watch of things. Father suggested that some big heavy stones laid on the cover of the barrel would prevent a similar mishap; and he said I had better have some water somewhere else so the chickens would not be absolutely dependent on my new watering-apparatus.

Now look here, boys and girls. This pullet was the mother of eight chickens when she was 174 days old; and, by the way, is it not a little funny that a White Leghorn should want to sit so early in life when the Leghorns are considered as non-sitters? Well, I suppose we could easily breed a strain of precocious pullets. Now, suppose you start a "hen farm" and see how many chickens you can get from one mother, say in just a couple of years. It will be something like my potato experiment where I am trying to determine how many potatoes can be grown from one single tuber in twelve months.

And, by the way, there is a sequel to the above story. The feed that was given these chickens is a new "balanced ration" manufactured expressly for the purpose. The chickens are given all they can eat up clean three times a day. It contains every thing necessary for their health and comfort, and is manufactured by Houston Bros., Middletown, N. Y., so it can be sold at about \$20 a ton, if I am correct.

Just as I am closing, my eye glances again at the picture of the youthful mother; and I want to say once more to you all, "*Isn't she a beauty?*" Why, I would give more for that picture made life size, and hung up in my room, than for one of the valuable paintings by the old masters.

## Speci I Notices by A. I. Root.

### MEDICINES FREE OF CHARGE.

With the advent of better times, especially better times for the farmers, swindles of all kinds seem to have revived wonderfully—especially medicines furnished free of charge, to cure certain diseases. Just open your family papers, any of them, and look at the offers—a big case of medicine by mail, postage paid, just for the asking. The editor frequently helps, or at least allows himself to be appealed to. Well, I have quite a lot of these free medicines. Some of them I have taken, and some of them I have not got around to yet. This thing I have discovered, however: As soon as you send for a free bottle of medicine, especially if you tell what ails you, you are flooded with circulars. For instance, I sent for a "sure cure" for asthma. In a few days letters came from different quarters saying they had been informed I was a sufferer from that dread disease; and I must confess that their pleas for a little money were so touching I felt almost sorry for the time being that I did not have the asthma so I could help these medical missionaries in their praiseworthy work of benefiting mankind. Now, look here, my friend: These rascals have discovered that the man or woman who reads the advertisements, and sends for a bottle of medicine free of charge, is one of those who take medicine and are likely to be attracted by every new thing. They send their remedy free of charge, in order to get the names of medicine-buyers, and are certainly reaping a rich

harvest or they would not pay hundreds of dollars for the insertion of their advertisement in expensive periodicals. Why, you will see a whole-page advertisement with a picture of the wonderful Smith or Green, who made the discovery, almost as big as life. Judging from my own experience, I do not believe it is healthy business even to read medical advertisements and testimonials. It is the Electropoise right over again. No matter what medicine the patient takes, he is restored as if by miracle. In fact, a lot of the advertisements do read, "Almost a miracle."

### HUMBUGS AND SWINDLES BESIDES ELECTROPOISE AND OXYDONOR.

A new fad has come up in the same line, called "Elektrikure." It is the same thing, only cheaper and more ridiculous than any of the others. The silly twaddle about taking oxygen out of the air and introducing it into the body is all gone over. Then follows the usual list of startling testimonials. Circulars have come to us from Florida, California, and other remote places, indicating that they are trying to introduce it where people have not yet been posted. Of course, the thing cures every thing—cancer, consumption, and all other slight ailments of the flesh. One of our correspondents humorously tells us about the reception he gave it, as follows:

*Ed. Gleanings*.—Not long ago one of those Elektrikure frauds made me a visit and left his circular. I gave him a full dose of A. I. R.'s medicine found in Aug. list GLEANINGS. It didn't seem to set very well on his stomach, but I have faith to think it will do him good. Inclosed find circular. J. H. HART.  
Hanford, Kings Co., Cal., Oct. 29.

And here is another letter on this same subject, which illustrates most vividly how much harm a minister of the gospel may do in letting his imagination run away with his better judgment in regard to such things:

*Dear Sir and Friend*.—It has been my pleasure to read many interesting letters from you, and I have for a long time wanted to write and thank you for the stand you take with the frauds.

I believe every word you say about Electropoise. Can't you tell us something about Elektrikure? There is a minister here preaching "Elektrikure." I believe him and his machine to be a fake.

Since reading your letters my mind has changed considerably in looking to Christ Jesus for strength and happiness; and before you hear from me again I think I will be a member of the Church. I would have done so before this but for such people as the Elektrikure preacher. J. M. LASSITER.

St. Petersburg, Fla., Sept. 24.

### ACETYLENE GAS.

In the November *Cosmopolitan* are some facts given about acetylene that conflict with statements made by you in a recent number of GLEANINGS. Prof. Jacobus finds that calcium carbide will have to be furnished for \$19.50 per ton to compete with ordinary gas. You say it is as cheap as kerosene at 10 cts. per gallon. I see that calcium carbide is over \$80.00 per ton. Now, as you were the first to draw our attention to the new light, we rely on you to see that we are not humbugged. JOHN MAJOR.

Cokeville, Pa., Nov. 1.

Friend M. I saw the article you allude to, but I do not believe Prof. Jacobus is posted on all points. The price I gave, 4 cts. per lb., was, if I am correct, the retail price. Carbide will come down in price as the demand increases. One day last week, in passing a hardware store in Shelby, O., I happened to glance through a window, and the beautiful light reminded me of something familiar. I ejaculated to my companion, "Acetylene gaslight, as sure as you live." A crowd was already standing around the apparatus. Four burners lighted up the front part of the store beautifully. Said I: "Friends, how long has this apparatus been running here?"

A gentleman near me replied "Just one hour and twenty minutes."

It was the introducer of the apparatus. When I warned the crowd they had better stand back or they would all get blown up, the proprietor of the machine was going to "blow me up" until he saw I was just joking. Said he, "How can the gas blow anybody up when it is manufactured only as fast as it is consumed by the burners?"

His apparatus, running four burners, cost \$90, and he said the expense of the carbide was only half as much as that of kerosene, providing you use kerosene lamps enough to give an equal quantity of light. The flame was very small—much smaller than an ordinary gas jet—but it diffused a most clear soft white light, reminding one of very bright moonlight. He said the machines were made in Dayton, O., and that he was introducing them into stores just as fast as he could get the machines, and that they were behind with their orders. This was the statement of the agent who sets up the machines. I give it to you for what it is worth. I forgot to ask him the present price of the carbide.

#### DISCRIMINATING AGAINST HUMBUG AND SNIDE ADVERTISEMENTS.

We are very much pleased to receive the following notice from one of our respectable agricultural papers:

#### MISSING-WORD ADVERTISEMENTS.

The publishers of *Home and Farm* have accepted several advertisements in which the principal feature is an offer to distribute cash or other prizes to persons who supply letters to complete names given with blank spaces. These were accepted from well-known and reputable advertising agencies; but the course of events seems to justify our excluding advertisements of this character from our future issues, for the good of our subscribers and advertising patrons generally.

Advertisers and advertising agencies interested are accordingly.

HOME AND FARM.

Louisville, Ky.

I have been satisfied for a long time that there was some swindle about all this class of advertising, but I have never taken the pains to investigate just where the humbug came in. A short time ago cash was sent us in advance to advertise a "splendid razor" given to anybody who would send ten cents. We sent the money, and got a very small cake of shaving-soap. When we read the advertisement more carefully there certainly was a very small chance to make out by the wording of their advertisement that all they offered was the soap for ten cents. I think it behooves every respectable periodical to refuse all advertisements that are purposely made blind.

#### GOING WITHOUT YOUR BREAKFAST, ETC.

In commenting on this "cu e" in another column, I omitted to mention that the good people of Battle Creek, Mich., who make the health foods, have practiced for years the two-meal-a-day system. They, however, have a very late breakfast, and a second meal somewhere between two and three in the afternoon. Now, just one thing more: When you are traveling you can save quite a little money by omitting breakfast. Of course, you would have to have your two meals at about the time other folks do; but, if by omitting breakfast, you can save money, save doctor's bills, and feel ever so much better, why not give it at least a trial—especially if you have not got either money or health to throw away?

#### POTATOES FOR PREMIUMS.

Every person who sends us \$1.00 for GLEANINGS may have 25 cents' worth of potatoes as per list mentioned above, providing he asks for no other premium; and every subscriber who succeeds in sending us a new name—that is, who introduces GLEANINGS into a family or neighborhood where it has not been going, may have 50 cents' worth of potatoes. But please remember we can not pay postage on premium potatoes. Selling postage-stamps does not afford very much profit; neither is there very much margin to give away postage-stamps as premiums for getting subscribers. Potatoes are so bulky and heavy that it is very much better to have them sent by freight with other goods. As a rule it is expensive business to send them by express. Where you want only a potato or two to put in your garden in order to get a start with some of the newer varieties it may pay very well, especially where you live a long way off, to have them sent by mail or express. But where we give them away, please do not ask us to pay postage ourselves. For several seasons a good many have said, "Send me the 25 cents' worth of potatoes by mail. If you can not send a pound, send as many as you can, taking the postage out of the 25 cents." Now, please bear in mind we can not pay any of the postage out of the 25 cents. We give you the potatoes freely and gladly, because we want you all to make a test of the new varieties in your locality; but if wanted by mail, send 10 cents per lb. for postage, etc. Our new seed catalog, describing the po-

tatoes and every thing else we advertise, is now ready to mail on application. The two most promising varieties of potatoes, in my opinion, just now, are the Bovee and Maunum's Enormous. The Thoroughbred has now been so thoroughly introduced that we offer it for sale right along with the standard varieties and at the same prices.

#### SEED POTATOES.

The way the best early potatoes are being called for, and by the many inquiries that come from seedsmen, and dealers for the best varieties of early potatoes, we imagine there will be a scarcity next spring. In fact, a great many early potatoes grown for seed were this fall sold for table use as fast as they were dug, on account of the large prices that have been offered for them. Our potatoes are all dug and safely put in the cellar—something like 2000 bushels. No rot has yet appeared on any of our potatoes, and we are pouring them out of the boxes and looking them over carefully every week to see that we don't get caught. Our whole lot of 2000 bushels is stored in slatted bushel boxes, thus giving them plenty of air, and affording ease of access in looking them over. Since our last digging we have some more choice seconds. At present we can fill orders promptly for seconds of the following varieties: White Bliss Triumph, Thoroughbred, Early Ohio, Freeman, Monroe Seedling, Sir William—all at \$1.50 per barrel, except Monroe Seedling and Sir William. These, while they last, are only \$1.25 per barrel. For prices of firsts, see page 756, Oct. 15. We have also a few Bovee and Maunum's Enormous, seconds. Prices, \$1.00 and 75c respectively.

#### BEANS AT LOW PRICES.

You will see by our new catalog that we offer two kinds—Best of All and Navy—at \$1.25 a bushel. This is because we have a very large stock—not because they are in any way inferior. We also offer Mills' Banner bean, one of the very best field beans ever introduced, for only \$2.50 per bushel. The two first mentioned are well worth the price asked for a bean for table use.

*Light without oil.*

*Heat without fuel or fire.*

*Power without belting, pulleys, or shafting.*

The first two are already realized in our own home, and the latter is beginning to be realized in our factory. None of these things were realized or thought of fifty years ago. What will the next fifty years bring forth? Who can tell?

## DON'T FAIL, Try Again.

Send for our 36-page catalog full of information about bees, hives, bee-fixtures of all kinds, new improvements ahead. Keep up with the times.

### A. I. Root Co.'s Goods by the Carload

kept in stock. Shipped to you on short notice at less freight. Prepare early for the coming season.

N. A. KNAPP, Rochester, Ohio.

**A Boundary Dispute.**

That is what many line or "party" fences become. "Good fences make good neighbors." Never heard of a quarrel "over, through or under" **Page Fence.**

**PAGE WOVEN WIRE FENCE CO., Adrian, Mich.**

Read what J. I. PARENT, of Charlton, N. Y., says — "We cut with one of your combined Machines last winter 50 chaff hives with 7-inch cap, 100 honey-racks, 500 broad frames, 2000 honey-boxes and a great deal of other work. This winter we have doubled the amount of bee-hives, etc., to make, and we expect to do it all with this saw. It will do all you say it will." Catalog and price list free. Address W. F. & JOHN

BARNES, 515, Ruby Street, Rockford, Ill.

When more convenient, orders for Barnes' Foot-power Machinery may be sent to

THE A. I. ROOT CO., Medina, O.

**Moore's Strain of Italian Bees.**

Eighteen years ago J. P. Moore, of Morgan, Ky., commenced rearing Italian queens with the object of improvement constantly in view; and, as a result, he is to-day the happy possessor of a strain of bees noted for superior honey-gathering qualities throughout the U. S. and Canada. If you could step into his office and peruse the stacks of testimonials from customers you would soon become a customer too. Descriptive circular sent on application.

**Do You Want An Incubator?**

An Honest Machine, Honestly Built, Guaranteed.

**"NEW AMERICAN."** Want Our Catalogue? It's a pretty book of 68 pages, finely illustrated; worth dollars to every poultryman. A 2c stamp gets it. **Geo. J. Nissly, Saline, Mich.**

## BEEWAX.

The market for beeswax has held up remarkably well this fall, so that we are justified in going back to the prices which we paid all last spring—25 cts. cash, 27 in trade, for average wax delivered here. We expect to need 50 to 60 tons of wax the coming season, and can therefore use all the pure beeswax you can send us. For choice clean bright yellow we usually pay an extra cent or two.

## THE PLAIN (NO-BEE-WAY) SECTIONS AND HOLDERS WITH FENCE, OR CLEATED SEPARATOR.

In another column you will find a description and illustration of the new plain section-holder with fence and plain section. These plain section-holders for the regular  $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$  plain section, which, when filled with honey in connection with the fence, hold a scant pound, are of stuff  $\frac{1}{4}$  inch thick for ends and bottom, dovetailed at the corner, and  $1\frac{1}{2}$  inches wide. They are  $17\frac{1}{2}$  inches long, outside measure; and to use them in the regular super a piece  $\frac{3}{8}$  inch thick at the bottom edge, and tapered to a sharp edge at the top, is nailed into the super ends, the tin strip projecting at least  $\frac{1}{4}$  inch further in than this cleat. The beveled cleat guides the plain section-holders into place, and they and the fence are supported on the tin strip.

The fence is made up of four slats lengthwise, and grooved and cross cleats, as shown, all put together with glue, in a machine specially constructed for the purpose. These fences will, of course, be made slightly different for use with various styles of surplus arrangements. For instance, the regular fence used with plain section-holder could not be used without alteration in the T super. It will also require changing slightly to be used with plain sections in the old-style slotted section-holder. Likewise the  $4 \times 5$  section will require a somewhat different fence. In view of this it will be quite necessary, when you order the fences separately, to be very particular to designate for what style of surplus arrangement they are to be used. The price of the plain (no-bee-way) sections will be the same as any other style of the same size. The price of the plain section-holders will be \$1.00 per 100; and the double or single cleated fences we expect to supply at \$1.00 per 100, all put together. We will not furnish them not put together, as very few would have the facilities or skill to put them up properly, and compete with our automatic gluer. Our system of hive-numbering will remain the same as last season, with the idea of designating letters carried still further. The letter P for plain sections and holders, added to the hive number, will indicate that the super is to be fitted with plain section-holders and fences. The letter Q will indicate that the supers are to take  $4 \times 5$  sections in plain section-holders with fences. R will indicate a super with rack as used by Miles Morton, and sections  $3\frac{3}{4} \times 5$  with fence. S will indicate the old-style arrangement with slotted section-holders and separators. T will indicate the T-super arrangement for  $4\frac{1}{2}$  plain sections and thumb-screws.

AD52P, AD52S, and AD52T will be the same price as have listed in our catalog as AD52. That is, hives equipped with the new sections and fences will be the same price as the regular hives last season. AD52Q and AD52R, having deep supers, will be 5 cents each extra. Such a hive two story, as AD52Q and AD52R, would be 10 cents each extra. Hives will be furnished with the staple-spaced thick-top frame instead of the Hoffman at the same price.

## Two Papers for the Price of One.

The **Farm Journal**, of Philadelphia, a monthly agricultural journal of 16 pages, sent **One Year Free** for one subscription to **Gleanings**, with \$1.00, paid in advance, either new or renewal. In the case of a renewal, all arrears, if any, must be paid in addition to one year in advance.

The **Farm Journal** is now in its 20th volume, and takes the lead among all the *low-priced* agricultural journals of this country and of the world. It gives no chromos, pulls no swindles, inserts no humbug advertisements, lets other folks praise it, and makes good to subscribers any loss by advertisers who prove to be swindlers. The editor was born on a farm and reared at the plow-handles, and the contributors are practical men and women.

The regular price of this excellent journal is 50 cents a year, and it is well worth it; but by special contract with the **Farm Journal** we are enabled to make the above very liberal offers.

THE A. I. ROOT CO., Medina, Ohio.

## A Bargain!

**Only \$1.50.** We have made arrangements to furnish **THE OHIO FARMER**, of Cleveland, Ohio, and **GLEANINGS IN BEE CULTURE**, both papers, for only \$1.50.

The **Ohio Farmer** is well known as one of the very best, largest, and among the leading agricultural papers of America. A 20-page, 80-column paper **EVERY WEEK** in the year; employs **THE VERY BEST WRITERS** that money can procure; a strong, fearless defender of the agricultural interests of this country, and **CLEAN** in both reading and advertising columns. **IT HELPS MAKE THE FARM PAY.**

THE A. I. ROOT CO., Medina, Ohio.

## Gleanings in Bee Culture

AND

## American Agriculturist.

Weekly.

**BOTH ONE YEAR ONLY \$1.25.**

By special arrangement with the publishers, we are enabled to offer the **American Agriculturist** in combination with **GLEANINGS IN BEE CULTURE** at the unparalleled low rate of \$1.25 for both papers one year. The **American Agriculturist** is published in five editions. The N. E. Homestead, the Eastern, Middle, and Southern editions of **American Agriculturist**, and the **Orange Judd Farmer**. Each contains matter relating to its own locality, as well as the latest and most accurate market reports for the country in general. It has departments relating to all branches of farming, articles written by the most practical and successful farmers, supplemented with illustrations by able artists. Short stories, fashions, fancy work, cooking, young folks' page, etc., combine to make a magazine of as much value as most of the special family papers.

A sample copy will be mailed **FREE** by addressing **AMERICAN AGRICULTURIST**, Columbus, O., or New York, N. Y.

**TAKEN** separately these two papers cost \$2.00, consequently every subscriber under this offer will get

**\$2.00 IN VALUE FOR \$1.25.**

**Premium Books.** For 10 cents extra, as postage, you can have your choice of any of the following standard books **FREE**: "Profits in Poultry," "Farm Appliances," or "Farmer's Almanac" (ready December 15). Send your subscriptions direct to

THE A. I. ROOT CO., Medina, Ohio.

**Pocket-knives Free.**

**A Rare Opportunity to Secure Good Pocket-knives.**

In preparing this list of pocket knives we have selected only the best American hand-forged blades, which are warranted to give good service, and not flimsy imported trash, which generally proves to be a nice shuck and poor meat. These knives are made of the finest crucible steel by American workmen, carefully tempered and sharpened, ready for use, and warranted free from flaws, and firm in temper, but not made for screw-drivers, chisels, or nail-pullers.

**Boy's American Knife, No. 150,** one blade, sharp point; length, closed, 2½ inches. Each 10c; doz. \$1.10; postage, each, 3c.

**Boy's American Knife, No. 10½,** one blade, same as above, but round point. Just the thing for little fellows. Each 10c; dozen \$1.10; postage, each, 3c. Two of either the above free for your own renewal with \$1.00.

**Boy's Knife, No. 252,** two blades; length, closed, 3 inches, iron lined, ebony handle; just right for a boy who has become too big for a one-bladed knife. Each 20c; dozen \$2.25; postage, each, 3c, or three free for one new subscriber and your own renewal, with \$2.00, or one free for your own renewal with \$1.

**Barlow Knife, No. 170E,** one blade; length, closed, 3¼ inches. This knife has been our leader for years, and is still as good as ever. Each 50c; ½ dozen 80c; dozen \$1.50; postage, each, 4c, or five of the above knives free for one new subscriber and your own renewal with \$2.00, or two given for your own renewal with \$1.05.

**Barlow Knife, No. 270E,** two blades, otherwise as above. Each 25c; ½ dozen \$1.30; dozen \$2.50; postage 4. Three of the above knives free for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Our No. 209 "Rustler" Knife,** one large spear-point blade; length, closed, 3½ inches; ebony handle; the best one-bladed knife on the list. Each 20c; ½ dozen \$1.15; dozen \$2.25; postage, each, 5c, or three free for one new subscriber and your own renewal with \$2.00, or one free for your own renewal with \$1.00.

**Our No. 235 Farmer's Knife,** two blades; length, closed, 3¼ inches; almost the same thing as the "Big Bargain" knife we sold some years ago, which we were at that time unable to replace, and consequently were obliged to drop from our lists. We should take pleasure in taking Uncle Sam's place and present you these handsome knives ourselves. We can furnish this knife in either clip or spear point, at the low price of 30c each; ½ dozen, \$1.60; dozen \$3.00; postage, each, 5c. Three given for one new subscriber and your own renewal with \$2.15 or one for your own renewal with \$1.05.

**Our No. 235 "Renewal" Knife.** Like the above cut, but no shield on the handle. There's surely 25 cents' worth in this knife. It has two strong blades; length, closed, 3¼ inches. We expect to give hundreds of these knives. Each 25c; ½ dozen \$1.30; dozen \$2.50; postage, each, 5c, or three free for one new subscriber and your own renewal with \$2.00, or one free for your own renewal with \$1.00.

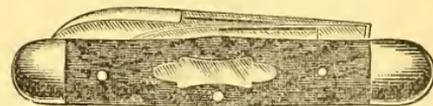

**Our Excelsior Knife, No. 46,** two blades, brass lined, German silver tips, cocoa handle. This knife is usually sold for 60 to 75 cents. We bought 57 dozen of them, which is ample explanation for the price we make. Each 40c; ½ dozen \$2.00; dozen \$3.75; postage, each, 5c, or two free for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.15.

**Our Hard-service Knife No. 878,** two blades; length, closed, 3½ inches; brass-lined, German-silver tips; the large blade is extra strong and wide; either ebony or cocoa handle. A knife that hunters and farmers will appreciate. Each 45c; ½ dozen \$2.50; dozen \$4.50; postage, each, 5c. Two given for one new subscriber and your own renewal with \$2.15, or one given for your own renewal with \$1.20.

**Medium Diamond Knife, No. 0213,** two blades; length, closed, 3¼ inches; same shape as No. 2255, but not quite so thick; bone, cocoa, or ebony handle, inlaid. Each 45c; ½ dozen \$2.40; dozen \$4.60; postage, each, 5c, or two given for one new subscriber and your own renewal with \$2.10, or one given for your own renewal with \$1.20.

**Our Diamond Knife, No. 2255,** two blades; 3¼ inches long, closed; diamond-shaped handle, large in the middle, gracefully curved to the end; blades are razor steel, hand-forged, brass-lined; German-silver tips and ebony handle. Each 50c; ½ dozen \$2.50; dozen \$4.80; postage, each, 5c. Two given for one new subscriber and your own renewal with \$2.25, or one given for your own renewal with \$1.25.

**Our Hawk-bill Pruning-knife, No. 714;** length, closed, 4½ inches; heavy blade; cocoa handle, steel capped and bolstered. Each 50c; dozen \$5.75; postage, each, 6c. Two given for one new subscriber and your own renewal with \$2.25, or one given for your own renewal with \$1.25.

**Medium Pruning-knife, No. 725.** This knife has a looked blade about the same size as No. 714, but not quite so thick, and handle not capped. Each 35c; dozen \$4.60; postage, each, 4c. Two free for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.10.

**Small Pruning-knife, No. 000.** This is a smaller knife, made for pruning; can also be used for a pocket-knife. Each 25c; dozen \$2.75; postage, each, 4c. Free for your own renewal with \$1.00.

**Pen-knives.**

**Ladies' Pen-knife, No. 213,** two blades, ivory handle; length, closed, 2½ inches; brass-lined; blades, extra-fine steel. The illustration does not do this knife justice. The same knife we formerly sold for 35 cents. Each 25c; ½ dozen \$1.40; dozen \$2.70; postage, each, 3c, or three free for one new subscriber and your own renewal with \$2.00, or one free for your own renewal with \$1.00.

**Queen-cell Knife, No. 278-N**, two blades; brass-lined; German-silver tips; extra-fine steel; length, closed, 3 inches. We have this knife made expressly for us, and branded with our own name. You can't buy it at any other place on earth. It's the neatest pocket-knife made—a handsome present for either ladies or gentlemen. Excellent for cutting out queen-cells. Each 35c; 1/2 dozen \$1.80; dozen \$3.75; postage, each, 3c. Two free for one new subscriber and your own renewal with \$2.00, or one free for your own renewal and \$1.10.

**Automatic Knife.** "Just touch the button, and the blade opens." Aluminum handle, two blades, 3 1/4 inch, finest razor-steel blades. This knife is a great novelty as well as a great convenience, as it may be opened with one hand—something which can not easily be done with a common knife. These knives are used by ladies and gentlemen through the United States and Europe. Each 60c; 1/2 dozen \$3.10; dozen \$3.10; dozen \$6.00; postage, each, 5c. Given free for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.35.

**Aluminum Penknife, No. 328**, two blades about same size as automatic, but made in the ordinary way, with aluminum handle; blade extra-quality steel. Buy one of these knives and you will always have a sample of the new metal (aluminum) with you to show your friends. Each 25c; 1/2 dozen \$1.50; dozen \$2.50; postage, each, 2c. Three free for one new subscriber and your own renewal with \$2.00, or one free for your own renewal with \$1.00.

**Razors.**

We have barred all German corn-knives from this list, and offer razors that we know are good. Postage on all razors 5c each, or sent registered for 13c. All razors positively guaranteed to be as represented.

**No. 126. Our "Panic" Razor**, 5/8 inch blade, square point. Nothing better for the price. Each 75c, given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.50.

**No. 455. Goldenrod Razor**, 5/8-inch blade; full hollow ground; quality and finish, super extra; none better on earth for the price. Each \$1.75. Given for two new subscribers and your own renewal with \$3.50, or your own renewal with \$2.50.

**Our Hamburg Razor.** Ground rattle razor, full hollow ground, best of steel; square pointed; warranted. This razor is usually sold at \$2.00 by retail merchants. Each \$1.25. Given for one new subscriber and your own renewal with \$2.50, or your own renewal with \$2.00.

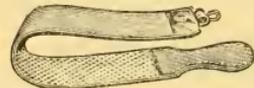

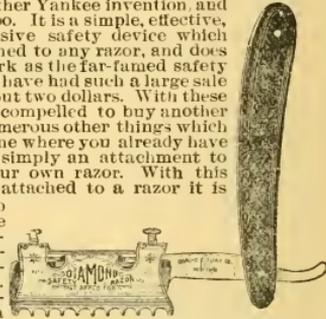

**No. 502. "Crescent" Razor**, 5/8-inch blade, extra hollow ground; fancy celluloid handle; a beauty.

Each \$1.50. Given for one new subscriber and your own renewal with \$2.75, or your own renewal with \$2.25.

**No. 03647. Wostenholm's New Pipe Razor**, 5/8-in. blade; finest quality, hollow ground; a little gem, and a dandy shaver; no better steel put in a razor. Every one likes them. Each 90c. Given for one new subscriber and your own renewal with \$2.15, or your own renewal with \$1.65.

**Bridle Your Razors.—The Diamond Razor-guard.**

This is another Yankee invention, and a good one too. It is a simple, effective, and inexpensive safety device which can be fastened to any razor, and does the same work as the far-famed safety razors which have had such a large sale of late at about two dollars. With these you are not compelled to buy another razor and numerous other things which are of no value where you already have a razor, but simply an attachment to attach to your own razor. With this little device attached to a razor it is impossible to cut one's face while shaving, no matter how hurried you are. We have purchased a quantity at prices so we shall offer them at the low price of 25c each or \$2.25 per dozen, or will give one free for your own renewal with \$1.00. Full sheet of directions accompany each one.

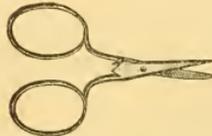

**No. 50. Swing Razor-strop.** Nothing but for the purpose. Each 25c, postage 5c. Given for your own renewal with \$1.00.

**Swing Razor-strop**, made of extra heavy genuine horsehide; buffed leather; fine woven web; strong sewed leather handle; plated swivels. Each 45c, postage 5c. Given for your own renewal with \$1.20.

**Monarch Razor-strop**, four sides; combination bone and belt; padded leather cushion; solid leather; brass side, inlaid bone, screw handle. Each 45c, postage 10c. Given for your own renewal with \$1.20.

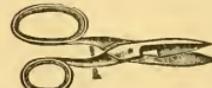

**Scissors and Shears.**

**Lace-scissors, No. 858.** 3 1/2 inches in length; best quality of steel, highly nickel-plated; also used for clipping queens' wings. Each 25c; doz. \$2.60; postage, each, 3c. Given for your own renewal with \$1.

**Ladies' Scissors, No. 400.** 4 1/2 inches in length; superior quality; warranted extra-fine; nickel-plated; nothing better. Each 35c; dozen \$3.60; postage, each, 3c. Given for your own renewal with \$1.10.

**Button-hole Scissors, No. 800.** 4 1/2 inches long; blade beveled; has screw on the side, adjustable for cutting different sizes; polished. Each 50c; dozen \$5.00; postage, each, 4c. Given for your own renewal with \$1.25.

**Button-hole Scissors, No. 825.** 5 1/4-inch. Positively the best made; extra cast steel, beveled edges, crocus finish, full nickel-plated, with tension spring, adjustable to any hole. Each 75c; dozen \$8.00; postage, each, 5c. Given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.50.

**Barbers' Shears, 7-inch, extra-fine steel;** warranted to be of superior quality; are full nickel-plated. Each 60c; dozen \$6.50; postage, each, 5c. Given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.35.

**Barbers' Shears, 8-in.,** as above. Each 65c; dozen \$7.00; postage, each, 5c. Given for one new subscriber and your own renewal with \$2.00, or your own renewal with \$1.40.

**"Big Bargain" Shears.** In consideration of the large quantities of Leader shears we have placed on the market during the past few years one of the largest shear-manufacturers has offered us shears made of solid steel, hardened and tempered (strictly first) at a price so we can furnish them at prices we formerly asked for seconds. The blades are put together with the Hatch patent bolt, as shown in cut. By the use of this invention there is no thread in shear; and with the brass nut, which is softer than screw, there is no chance for the thread-stripping. At the same time the rubber washer gives elasticity sufficient to allow the blades to move smoothly without grinding one another on the cutting edge. Each pair is full nickel-plated. Below we list five sizes at prices within the reach of all:

**BIG-BARGAIN SHEARS.**

| Num. | Size.     | Each | 1/2 doz. | Doz. | Post. | Renewal and |
|------|-----------|------|----------|------|-------|-------------|
| 1    | 6 1/2-in. | .25  | 1.50     | 2.50 | .06   | 1.00        |
| 2    | 7-in.     | .30  | 1.55     | 3.00 | .06   | 1.05        |
| 3    | 7 1/2-in. | .35  | 1.75     | 3.40 | .07   | 1.10        |
| 4    | 8-in.     | .40  | 2.00     | 3.90 | .08   | 1.15        |
| 5    | 10-in.    | .50  | 2.50     | 4.90 | .10   | 1.20        |

Ten per cent off the dozen rates in lots of three dozen of a kind.

**Knives and Forks.**

All these goods are standard, being known as "full tang," i. e., the steel of the blade extending *entirely through the handle*, thus giving the greatest attainable strength and durability.

Six knives and six forks constitute a set. All forks have three tines. All blades and tines are steel.

**Knives and Forks, No. 1308,** cocoa handles. Per set, six knives and six forks, 45c; postage, per set, 2c. Two sets given for one new subscriber and your own renewal with \$2.15, or one set given for your own renewal with \$1.20.

**Knives and Forks, No. 11756;** cocoa handles, with bolster; best quality. Set, six knives and six forks, 60c; postage, per set, 20c. Given for one new subscriber and your own renewal with \$2.15, or your own renewal with \$1.65.

**Knives and Forks, No. 12856;** cocoa handles, with bolster and cap; extra fine steel. This is the most serviceable set we ever sold, as it is impossible for the handles to come off. Set, six knives and six forks, \$1.25; postage, set, 30c. Given for one new subscriber and your own renewal with \$2.50, or your own renewal with \$2.00.

**Knives and Forks, No. 1884,** polished white bone finished handles, bolstered and coppered. Set, six knives and six forks, \$1.00; postage 40c. Given for one new subscriber and your own renewal with \$2.25, or your own renewal with \$1.75.

**Children's Knives and Forks, No. 1.** (Molets) Genuine cocoa handles, full tang, two rivets, well finished. Set, six knives and six forks, 50c; postage, set, 15c. One knife and one fork, 10c; postage

4c. Set of six given for your own renewal with \$1.25.

**Kitchen Knife, No. 1.** Jno. Russell's make; best quality, but small. Each 5c; dozen 50c; postage 3c. Five given for your own renewal with \$1.60.

**Kitchen Knife, No. 13.** Jno. Russell's make; extra-fine steel; the best kitchen knife made; also excellent to use as a paring-knife. Each 10c; dozen 98c; postage, each, 3c. Two given for your own renewal with \$1.00.

**"Lerder" Bread-knife,** 6 1/2 inch, polished steel, blade firmly set in finished hardwood handle; brass ferrule. Each 10c; dozen 85c; postage, each, 5c. Two given for your own renewal with \$1.00.

**Special Bread-knife,** extra quality steel; redwood handle; good enough for any one. Each 50c; dozen \$5.00; postage, each, 8c. Given for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.25.

**Corrugated Bread-knife.** The Christy and Clauss knives have had a large sale. Both of these have a straight blade with corrugated edge, and it is not so easily sharpened as a straight edge. The knife we offer overcomes this difficulty and still retains the corrugated edge. Because the blade is corrugated when it is ground with a straight bevel on one side, it makes the cutting edge corrugated, and accomplishes the desired result. Each 15c; dozen \$1.60; postage, each, 5c. Five given for one new subscriber and your own renewal with \$2.00, or two for your own renewal with \$1.05.

**Clauss Knife-set,** consisting of one bread-knife, one cake-knife, and one paring-knife, made of sheet steel, with nickel-finished iron handles. Per set of three knives, 20c; dozen sets \$1.80; postage, set, 15c. Three sets given for one new subscriber and your own renewal with \$2.00, or given for your own renewal with \$1.00.

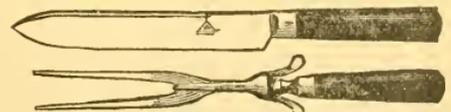

**Butcher-knife, No. 9,** six-inch blade, a cocoa-wood handle, well riveted; strong; the wonder of this department. Each 10c; dozen 95c; postage 5c. Seven given for one new subscriber and your own renewal with \$2.00, or two given for your own renewal with \$1.00.

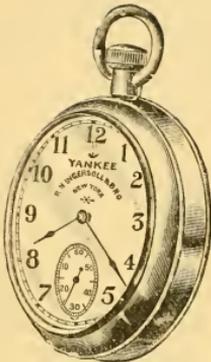

**Butcher-knife, No. 12,** 6-inch blade, Jno. Russell make; warranted extra quality. If you are looking for quality you can't beat it at any price. Each 25c; dozen \$2.10; postage, each, 5c. Three given for one new subscriber and your own renewal with \$2.00, or one given for your own renewal with \$1.00.

**Butcher-knife, No. 012,** nine-inch blade, as above. Each 60c; dozen \$4.85; postage, each, 8c. Two given for one new subscriber and your own renewal with \$2.25, or one given for your own renewal with \$1.25.

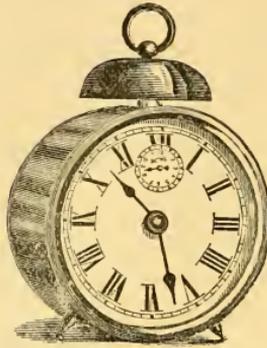

**Carving-knife and Fork,** swell handle, guard on fork; fine steel cocoa handles; warranted. Pair \$1.00; dozen pairs, \$10.00; postage, pair, 15c. Given for one new subscriber and your own renewal with \$2.25, or given for your own renewal with \$1.75.

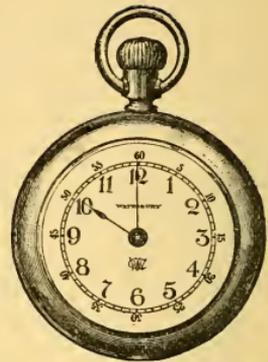

## THREE GREAT BARGAINS.

Yankee Watch.

Alarm-clock.

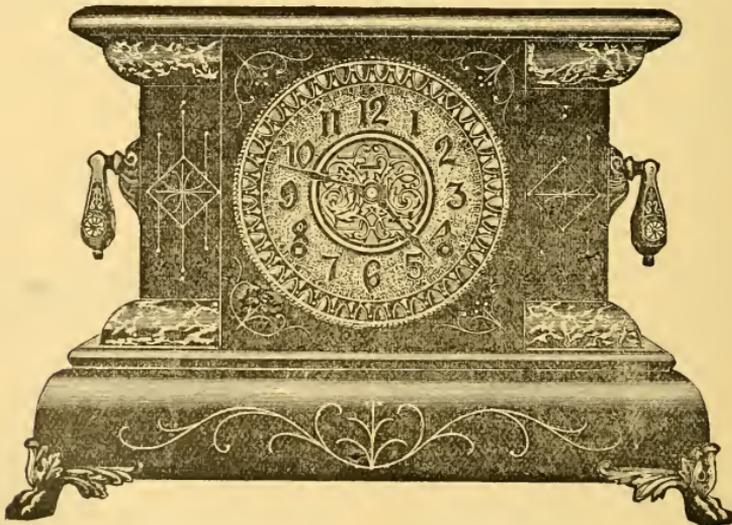

Ladies' watch.

**A Genuine "Yankee" for only \$1.00.** *One of the old timers that we aren't afraid to warrant.* The first of the above illustrations represents the *new thin model* "Yankee" watch. This is the lowest-priced guaranteed watch in the world. This is an 18-size American movement, patent short-winding device, fitted in an open-face nickel plated case, and has an unqualified guarantee for one year (contract with each watch). Just the thing for Young America's Christmas. Each only \$1.00. Given for one new subscriber and your own renewal with \$2.25, or prepaid for your renewal with \$1.75.

**Nickel Alarm-clock.** The adjoining cut shows our Early-riser alarm-clock. It is a marvel for the money. Only 75 cts., just half what we used to sell a similar one for. Given for one new subscriber and your own renewal with \$2.00, or for your own renewal with \$1.50. Postage 25c.

**Ladies' 7-jewel Watch.** *While this price lasts, no other cheap watch will be in it.* The illustration is a poor representation of our 7-jewel, 6 size, Waterbury watch complete in a neat nickel plated case. This is the same identical watch we have sold for years at \$4.00, and have had the least complaint from them of any watch we carry in stock. We have some special prices from the manufacturers, which enable us to offer them at the low price of \$2.50 each. Given for one new subscriber and your own renewal with \$3.75, or for your own renewal with \$3.25. Postage and register 15 cts. extra.

## SPECIAL PURCHASE OF "INGRAHAM" MANTLE CLOCKS.

Eight-day; Half-hour Strike; Cathedral Gong; Patent Regulator; Bronze-metal Trimmings;  
Height, 11 inches; Length of Base, 17 1-2 inches.

**WE** HAVE recently made arrangements with the manufacturers for a large quantity of these handsome clocks at a price that will enable us to retail them for the price they generally wholesale at. The cases are an imitation of French marble, and are a reproduction of the French designs in wood, highly polished, nicely engraved, and gilded. It has an eight-day strike movement, and all the late improvements, such as the turn-back attachment, polished pinions, &c. Every clock is thoroughly tested before it leaves the factory. We can furnish them in either white or gilt dial. In ordering always specify which. Our price each, packed in a box, only \$4.48. Given for one new subscriber and your own renewal with \$5.75, or given for your own renewal with \$5.25. Weight boxed, about 20 pounds.

# WATCHES.

In preparing the following list of watches we have used the utmost care to select strictly reliable goods, such as are made by the oldest watch-makers of America, who will never lower the standard of their goods to make a few extra dollars for the time being. Such firms have spent years in building up a reputation as being reliable, and will never allow seconds or inferior goods to bear their well-deserved trademark. Every reliable watch and case bears the maker's name stamped into the metal.

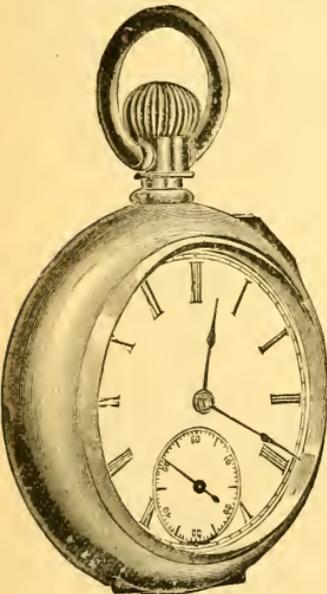

A gold-filled case consists of two parts of solid gold with one plate of composition metal between, all so thoroughly welded together that they practically form one piece. They wear as well as solid gold.

**Guarantee.** All movements sold by us, unless otherwise specified, are guaranteed for five years. This does not refer to the life of a movement, but that we will for five years from date of sale; correct, free of charge, any fault which may occur from defective material or workmanship, purchaser paying mail or express to and from factory. Any well made movement will last a life-time if properly cared for. Each case contains a guarantee signed by the manufacturers, which pledges them to make good any case that does not wear its allotted time.

**Cases.** We have selected what we think to be the best make of cases on the market, and can furnish our watches complete with any of the following makes: 14 K. 20-YEAR.—Joseph Fays & Co. "Monarch," Keystone Watch Co. "Boss," Illinois Watch Co. "Elgin Comm. under," Crescent Watch Co. "Crescent," "Crown," 10-K. 15-YEAR.—"Planet," Joseph Fays & Co. "Monarch," Keystone Watch Co. "Boss," 14 K., 5 YEAR.—"Royal," "Orient," "Cyclone," "Masot." The silverline will last a lifetime, and doesn't tarnish. Screw bezel silverline, 25 cts. extra; 16 and 18 size, open face, gold filled cases with screw-bezel, \$1.50 extra. If you are unacquainted with the various makes of cases let us, and we will give you the best.

At the close margins we sell watches we can not guarantee the price against the market fluctuations of standard movement cases, and as a 50 cent advance oftentimes takes all the margin we make; but will always bill at lowest ruling prices.

We advise shipping watches by express, as the companies agree to deliver them safely to any office in the U. S. prepaid. So always include 25 cents extra for express charges and we will guarantee safe delivery.

## Watches as Premiums.

To those who may desire to turn their commission for soliciting new subscribers to GLEANINGS towards a watch we will make the following liberal offer:

We will allow 50c for each new subscriber and 25c for each renewal, including your own, but sufficient money to cover the subscriptions and balance due on premiums must invariably accompany order. For example: You secure six new subscribers together with your own renewal, which would be \$7.00. The watch you select is listed at \$10, so together they would be \$17. Your commission would be six new subscribers at 50 cts., equals \$3.00; your own renewal 25 cts., which added together makes \$3.25. Deduct this from the \$17.00 and send us the balance, which is \$13.75, making the watch cost you only \$6.75.

## Our Celebrated Farmers' Watch.

These watches are as standard as wheat, and are sold the world over at almost double these prices. Handsome and durable 3-oz. Dueber silverline case, 18 size, inside cap, stem wind and lever set; hinge open face or hunting case.

## The New "Sun-Dial" Movement.

Made by the Celebrated Elgin Watch Co.

The new "Sun-dial" is practically the Atlas movement improved, and is made by one of the best of American watch-makers, with a view of competing with the cheap imported watches shipped to this country every year. They are 7-jewel nickel movement, with safety-pinion and poised balance, and are guaranteed to be first-class in every respect. Every movement guaranteed for two years. We have fitted these movements with many of the 18 and 6 size cases, as shown on the following pages.

will buy any watch on this page in a 5-year guaranteed case, complete with 7-jewel Elgin or Waltham movement.

## Designs in Cases.

We can furnish these handsome designs in 5, 15, or 20 year cases.

**OUR PRICE** IS from 25 to 50 per cent lower than retail jewelers generally ask for these same goods. Don't let any one tell you that they are seconds or inferior goods. Remember that Elgin and Waltham movements are the same the world over. Each movement and case bears the maker's name. The Elgin and Waltham people are never going to put out seconds under their hard-earned reputation as being reliable. It's nonsense. Such talk generally comes from a source where there is an ax to grind.

See premium offer for above watches on page 13.

Honey Column.

CITY MARKETS.

MILWAUKEE.—This market continues about the same on honey as reported by us last. The supply is very good, and the quality and condition are uniformly very acceptable. We should enjoy a more active demand, yet do not propose to complain, and trust good results will follow the shipments. We quote white 1-lb. sections, No. 1, 12@13; No. 2, 10@11 amber, No. 1, 8@10; extracted white in barrels and kegs, 5@6; dark, in barrels and kegs, 4@5; beeswax, 25@27.

A. V. BISHOP & Co.,  
Milwaukee, Wis.

Nov. 19.

NEW YORK.—Comb honey has been arriving rather freely; trade the past week a little more quiet. We quote our market to-day as follows: Fancy white clover comb, 11@12; fair white, 10@11; good white, 9@10—plenty of the latter here; fancy white comb honey, steady trade for; buckwheat comb honey, 7@8½; extracted honey, N. Y. State white clover, 5@5½; buckwheat, 4@4½; Southern, in demand, 5@5½; beeswax, 26@27.

FRANCIS H. LEGGETT & Co.,  
Franklin and Varick Sts., New York.

Nov. 22.

MINNEAPOLIS.—Market firm at 11@11½ for fancy white comb; No. 1, 10@11; fancy amber, 10; No. 1, 9; fancy dark, 9@9½; No. 1, 8@8½; fancy white extracted, 5@6; amber, 5; dark, 4@4½; beeswax, 22@25. Market has been and still is in good condition. Really fancy white comb honey in very good demand. While receipts have been fairly heavy, they have been kept down by a good shipping demand.

S. H. HALL & Co.,  
Minneapolis, Minn.

Nov. 19.

BOSTON.—The demand for honey has been lighter for the past 10 days owing to the holiday trade. Stocks are quite equal to demand, and prices well maintained at 13c for fancy white in cartons; No. 1 white, 11@12; fancy amber, 9@10; white extracted, 6@7; darker grades, 5@6.

BLAKE, SCOTT & LEE,  
Boston, Mass.

Nov. 20.

PHILADELPHIA.—Honey selling freely. We quote fancy comb, 14; No. 1, 12; amber 10; buckwheat, 9; extracted, 5; dark, 4; beeswax, 27. We are producers of honey; do not handle on commi-sion.

WM. A. SELSER,  
10 Vine St., Philadelphia, Pa.

Nov. 23.

BUFFALO.—There is no change in price of honey since our last quotation. I think there is a little better demand. Beeswax scarce, and in good demand at 27@28 for pure wax.

W. C. TOWNSEND,  
Buffalo, N. Y.

Nov. 26.

ST. LOUIS.—Comb, white, 24-lb. cases, 11@12½; amber, same, 9@10½; dark, same, 6@8; extracted white, in cans, 5@5½; in bbls. 4½@5; amber, in cans, 4½@4¾; in bbls., 5@4½; dark, 3½@3¾; beeswax, prime, 2½; dark, half price.

WESTCOTT COMMISSION CO.,  
213 Market St., St. Louis, Mo.

Nov. 18.

ALBANY.—There is a very good demand for comb honey, with no change in prices since last quoted. Clover is coming forward more freely. We quote fancy white, 13; fair to good, 10@12; buckwheat, 7½@8; mixed, 8@9; extracted dark, 4@4½; light, 5@6.

CHAS. McCULLOCH & Co.,  
Albany, N. Y.

Nov. 19.

CINCINNATI.—Demand for honey has somewhat improved, but prices are unchanged. We quote 3½@6 for best white comb honey. There is a good demand for beeswax at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,  
Cincinnati, O.

Nov. 24.

DENVER.—We can quote our honey market a little more steady, but the low prices still prevail. We are having good demand for our brand of extracted. No. 1 white comb honey, 10; No. 1 white extracted, 6; beeswax, 25.

R. K. & J. C. FRISBIE,  
Lockbox 1014, Denver, Col.

Nov. 21.

COLUMBUS.—Fancy white, 13; No. 1, 11@12. Demand good for all grades white comb. We are in the market for supplies.

THE COLUMBUS COMMISSION & STORAGE CO.,  
400-413 N. High St., Columbus, O.

Nov. 20.

DETROIT.—Comb honey in fair demand. Best white comb honey, 11@12; other grades, 8@10; extracted white, 5@6; dark, 4@5; beeswax, 25@26.

M. H. HUNT, Bell Branch, Mich.

Nov. 19.

CHICAGO.—Fancy white, 11@12; No. 1 white, 10; fancy amber, 8@9; No. 1 amber, 7; fancy dark, 7@8; No. 1 and mixed, 7; extracted white, 5@6; amber, 4½@5; dark, 3½@4; beeswax, 26@27.

R. A. BURNETT & Co.,  
163 South Water St., Chicago, Ill.

Nov. 18.

KANSAS CITY.—The receipts of comb honey are large; extracted, light; demand fair. We quote fancy white comb, 11@12; No. 1, 10@11; amber, 8@9; extracted white, 5½@6; amber, 1½@1½; beeswax, 20@24.

C. C. CLEMONS & Co.,  
Kansas City, Mo.

Nov. 19.

CLEVELAND.—Fancy white, 12@13; No. 1 white, 11@12; fancy amber, 9@10; No. 1 amber, 8@9; fancy dark, 7@8; white extracted, 6½; amber, 5½@6; beeswax, 28.

A. B. WILLIAMS & Co.,  
80-82 Broadway, Cleveland, Ohio.

Nov. 20.

FOR SALE.—25 bbls. extracted pure white-clover honey, very light in color, and of finest quality, at prices as cheap as the cheapest, quality of goods considered. Can put it up in any style of package. Write for price, stating quantity desired.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—Alfalfa honey light amber, in carload lots. 3¼ cts. per lb.; sample, 10 cts.

JOHN NIPPERT, Box 1051, Phoenix, Arizona.

FOR SALE.—Tons of honey, comb, at 7 to 12c per lb. Inclose stamps for samples of extracted at 4 to 6c, in 160-lb. kegs, f. o. b. N. L. STEVENS, Venice, N. Y.

FOR SALE.—Pure honey.—Clover, extracted, 6½ cts. per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City.

FOR SALE.—Good extracted white-clover honey and heartsease and Spanish needle. Either, price 5c per lb., 60-lb. cans, 2 in a case. Send stamps for samples.

JNO. A. THORNTON, Lima, Ills.

FOR SALE.—Goldenrod honey, extracted, in cans and barrels, cheap as the cheapest.

J. B. MURRAY, Ada, Ohio.

WANTED.—To buy quantity lots of fancy comb and gilt-edged extracted honey.

B. WALKER,  
Evart, Mich., or 611 Van Buren St., Chicago.

CHAS. ISRAEL & BROS.,  
486, 488 & 490 Canal St., Corner Watts St., N. Y.  
**Honey and Beeswax.**

Liberal Advances Made on Consignments. Wholesale Dealers and Commission Merchants. Established 1875.

**No cheap Queens to sell; but the best.**

Golden 5 band, or 3 band from imported mother. Untested, 75 cts.; tested, \$1.00.

L. BEAUCHAMP, Box 613 San Antonio, Texas.

# The Review at Reduced Rates.

The **Bee-keepers' Review** is \$1.00 a year, but, for the sake of getting it into new hands, and being able to begin the year with a large list, I will, until Jan. 1st, send free to each *new* subscriber, a copy of "Advanced Bee Culture," a 50-cent book of nearly 100 pages, that gives briefly but clearly the best methods of management from the time the bees are put into the cellar in the fall until they are again ready for winter—32 chapters in all. Those who prefer can have, instead of the book, 12 back numbers of the **Review**, the selection to be mine, but no two numbers alike. All who send \$1.00 now will receive the last four issues of this year free, and the **Review** will be sent until the end of 1898. If not acquainted with the **Review**, send 10 cents for three late but different issues.

W. Z. HUTCHINSON, Flint, Mich.

**Free! Free! Free!**  
 What's Free?  
**WHY, Danzenbaker's Bee-book,**  
 "Facts About Bees,"  
 Providing 2c for postage is included.  
 Tells all about my new hive, and system of management, particularly how to produce comb honey that will bring from 2 to 4c more than honey produced in the old way. Address  
**FRANCIS DANZENBAKER,**  
 Washington, D. C.

Philadelphia Office of

**THE A. I. ROOT CO.,**  
 10 Vine St., Philadelphia, Penn.

Now is the time to order

**Shipping - cases, Winter Cases,  
 Chaff Division-boards, etc., etc.**

Order from catalog; prices are same  
 as from factory.

**Another  
 Great  
 Clubbing  
 Offer!**

**Two Great Papers at Price of One.**

**GLEANINGS IN BEE CULTURE**  
 and the **PRAIRIE FARMER** (Chi-  
 cago), both papers for only \$1.00.

This offer is good either to new name or renewal, but in case of renewal all back subscription must be paid up in addition to the \$1 for the two papers. The **Prairie Farmer** is one of the leading farm papers, and is clean in both the reading and advertising pages.

Address All Orders to

**THE A. I. ROOT CO., Medina, Ohio.**

**Shipping=cases.**

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA.** Immense stock. All orders for cases or other goods shipped by return freight. Address

**JOS. NYSEWANDER, Des Moines, Iowa.**

**Weekly Bee Journal One Year for 25c.**

To every *new* subscriber who sends us \$1.50 before Jan. 1, 1898, we will mail a copy of Prof. Cook's 400-page cloth-bound book, "BEE-KEEPERS' GUIDE" (price \$1.25), and the **Weekly American Bee Journal** for one year. That makes the **Journal** only 25 cents—a trifle less than half a cent per number. Or, if any one now getting the **Bee Journal**, and whose subscription is paid to Jan. 1, 1898, will send us \$1.50, with a new name, we will mail the above book to the sender, and the **Bee Journal** for a year to the new name and address. We need hardly tell you what the **American Bee Journal** is; but if you are not acquainted with it, *write us for a free sample copy.*

Address

**GEO. W. YORK & CO., 118 Michigan St., Chicago, Ill.**

# GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

ILLUSTRATED SEMI-MONTHLY

Published by THE A. I. ROOT CO.  
\$1.00 PER YEAR MEDINA, OHIO.

VOL. XXV.

DEC. 1, 1897.

No. 23.

## STRAY STRAWS FROM DR. C. C. MILLER.

SLUMGUM, according to *Schles. Holst. Bztg.*, is worth \$7 a ton to mix with commercial fertilizers.

"IT TAKES FROM 7 to 15 pounds of honey to produce one pound of comb in the very best circumstances," says C. P. Dadant, *A. B. J.*, p. 691.

BEE-KEEPERS "must co-operate fully," says Prof. Cook, "and then they can get their rights. When this is done, bee-keepers will not be forced, or even asked, as they are now, to take 3½ cents per pound for the best honey!"—*Am. Bee Jnl.*, p. 692.

SOMNAMBULIST, the delightful dreamer of *Progressive*, has a cloud in his sky. A friend, innocent of the identity of the sleep-walker, told him to his teeth that he didn't like Somnambulist's writings. Never mind, Sommy, lots of us do—like 'em much. [Hear! hear!—Ed.]

I'LL TELL YOU just why the little cleats are better than grooves on smokers. The sharp edge of the cleat makes the smoker less likely to slip out of the fingers. A much weaker spring is required. But can't you make the outer edge of the groove sharp? [Yes, and we will do it.—Ed.]

THIN FOUNDATION without side-walls, made on the machine for the construction of which the members of the Mich. B. K. A. paid last winter, was used to some extent the past season by Mr. Aspinwall. Combs were delicate and fragile, but the foundation curls and warps terribly.—*Review*.

LIVE BEES, according to a decision at the world's postal congress at Washington last June, may be sent, after Jan. 1, 1899, as merchandise to all lands of the Postal Union. Maximum weight, 12 35 oz. Max. length, 11.8; width, 7.87; thickness, 3.94 inches.—*Luxemburg. Bztg.*

THE EDITOR of *Australian Bee Bulletin* is afraid the article of W. A. Pryal, in April GLEANINGS, about Tasmanian blue-gum, may hurt the reputation of Australian honey,

and protests that it is *not* a typical Australian honey, or a main portion of their honey crop. He pins his trust to the honey of the box-trees.

CHALON FOWLS' plan of having supers cleaned out may be a good one, but it has the fatal defect that, at the time I want supers emptied, I seldom have (and never want) colonies short of stores. But I see a ray of light for which I thank him, for it's possible that having only a small entrance to the super may make a difference.

RURAL FREE DELIVERY of mail has been tried experimentally in 29 States on 44 routes. First Ass't Postmaster-General Heath, in his report, says: "The general results obtained have been so satisfactory as to suggest the feasibility of making rural delivery a permanent feature of postal administration in the United States, not immediately or in all districts at once, but in some gradual and graduated form." Hurray for free delivery! [Hip, hip, hur—Ed.]

E. E. HASTY, in *Review*, begs to go slow in applying the Monnier cure of paralysis, and imperil but few healthy colonies at first " (putting a healthy family into the same room with a family that has leprosy)". He thinks the disease may be only temporarily dormant, and the proposed cure may spread it. [No, it would hardly do to try Monnier's cure on too large a scale; but I do think it would be a good idea to test it in a small way.—Ed.]

AN INQUISITIVE PERSON, Ernest, reading p. 811, about the flies troubling your head at your desk, paraphrases slightly a question of yours on page 586, and says, "But why have flies in your office at all? Why not have screens and screen-doors?" [You musn't ask questions that I can't answer; anyhow, you can tell that "inquisitive person" that it is possible to screen a single honey-room, while it may not be possible to screen the windows of a large factory. Our office is in one of our factory buildings—Ed.]

A HONEY-FAIR, lasting two days, has been successfully tried by the Hanover bee-keepers' society in Germany. For two weeks the dailies prepared the public, by articles about honey and the coming show, where pure honey could be obtained. Sixteen bee-keepers brought their wares, most of them being sold

out first day. Chunk honey was in special demand. All honey was guaranteed by society; a minimum price of 25 cts. for comb and 20 for extracted was set, but the actual average of comb was 30 cts. (one man got 35), and of extracted 22½.

**FALL INTRODUCTION.**—Remove a queen after breeding stops in fall; and with no brood in hive the bees are hopelessly queenless, a condition in which they never refuse a queen. So thinks W. Z. Hutchinson, and quotes Mr. Turner, who re-queens in fall and never lost a queen. [I had never thought of it before; but my own experience would lead me to believe that W. Z. and Mr. T. were right. But say, doctor, you did not tell us what *you* thought about it. Give us another Straw on the subject, and, by the way, tell us more what you think when you quote the opinions of the other fellows.—ED.]

**HONEY-CAKES.** The famous *lebkuchen* of Germany. Bring to a boil 2 lbs. honey with ½ pt. water. While still warm, mix with 2 lbs. flour; knead well and set away for some days (the longer the better). Then stir in 3 yolks of eggs, with flour, and plump 1¼ oz. bicarbonate soda previously dissolved in water. Mix well. Add, according to taste, 2 lbs. sugar, some crushed cinnamon, cloves, citron, and chopped almonds; knead well, roll out to a finger's thickness, and bake.—*F. L. Thompson in Review.* [That cake ought to taste good; but I should think such an array of stuff would be rather hard on a fellow's stomach. By the way, some of the Root women have been trying your recipe for honey caramels as given in the honey-leaflet "Food Value of honey." The caramels are just fine, and to my notion taste much better than the boughten ones, and certainly more wholesome.—ED.]

**PLEASE TELL WHY,** Mr. Editor, the name Danzy is given to the bottom-board that I described and illustrated long ago, and that you saw years ago on all my hives. [With the greatest of pleasure, doctor. When Mr. Danzenbaker came here and showed me his peculiar style of bottom-board I said, "Why, that is Dr. Miller's." And then we looked up the back volumes, and found where you had described something similar with an illustration, but not quite the same thing, although intended to accomplish the same purpose. The construction of Dr. Danzenbaker's bottom-board is quite different. Your floor was flat on one side, with a two-inch space on the other. Mr. Danzenbaker's has one-inch space on one side and ¾ on the other. Your board was made of ¾ flooring nailed on to two side-pieces, while you will note that Mr. Danzenbaker's is made up of ¾ stuff let into grooves of two side rails. And then, too, his is so constructed as to permit of a shrinkage and swelling of the boards without splitting. Your old board could not be used with the modern Dovetailed hive with no bee-space under the frames. The name "Danzy" is therefore applied to a *peculiar construction* of the bottom-board, and not to a board that may be used the same as you used yours.—ED.]

**SEPARATORS,** p. 814, are advised in shipping-cases, so when a section breaks down it won't break down others. But isn't it cheaper not to have the first one break down? I can't imagine a necessity for more than one section in a thousand breaking down, and that one section shouldn't be shipped. [Ye-s-s. If everybody were careful not to ship any honey that would break down, and the freight *smashers* were freight *handlers*, we should not need any no-drip shipping cases—that is, I mean cases with paper trays with little cross-cleats; and yet you yourself acknowledge these to be good. We can not take too many precautions. In the first place, ship only such honey as we feel tolerably sure will not break. Second, put it in no-drip shipping-cases. Third, put separators between them. The last two items cost but a mere trifle, and might save a hundred times their value in honey that might be broken down by freight-smashers or truckmen, who somehow are able to smash even the strongest trunks ever built, to say nothing of honey put up in the best way possible. We must provide for the unexpected, even though the "unexpected" may not happen once in a hundred times.—ED.]

**SORRY TO SAY,** Ernest, we're not nearly so smart as you want to give us credit for, p. 802. I can't say how much time we did devote to that honey crop, but I know that two of us did all the work except what help we had from Ghordis and Philo. Their help would amount in all to less than one man's work for two months. Perhaps one man would have done in a month what both of them did. So, "I know that two of us did all the work except" what Ghordis and Philo did—"perhaps what may be equivalent to two months' work." [Ah, I see—no, I don't, either. You haven't yet told us *how many* days you and your women-folks spent in harvesting the honey crop. You simply tell us that two of you did all the work except what Ghordis and Philo did, and that their work would be about the equivalent of two months. What I should like to know is this: Did you and your assistant spend *all* of your time during the other ten months in harvesting the crop, or were you busy a part of the time at something else? I know for one thing that you write for GLEANINGS, the *American Bee Journal*, and a number of other periodicals. I know, also, that you spend some time in Sunday-school work, and a little time in raising posies; perhaps some time in running a small farm—and in mowing "weeds and things" in front of your place. I know, also, that Emma helps a good deal about the housework. Now, what I am trying to get at is this: *About* how much time in days, of ten hours each, did you two spend in harvesting that crop, from the time of putting the bees into the cellar to the time of putting them in again? Just give us a good guess, if you can not do any better. The time, if get-at-able, would be very interesting for the reason that we then could arrive approximately at the cost of that honey per pound, making due allowance for interest on money invested in appliances, deterioration, and changes.—ED.]

Family Matters; Traveling over the Country;  
Something of the Resources of the Country.

BY R. C. AIKIN.

This is Oct. 26, 1897. The Muser has been absent from the columns of GLEANINGS for several months, and very busy months too. During these months the little owl that sits on the end of the ridge-pole has been frequently seen and heard, but the Muser had not time to reduce her wise looks to the language of common humanity. Now that the wind howls and snow flies this wintry day, we will get the Muser's thinking-machine oiled and polished, ready for grinding out wisdom. While the rust and gum are wearing off we will give a somewhat reminiscent muse or two on other than bee topics.

The editor was so kind as to prepare a picture of the family of which the Muser has the honor of being the male member. Just "w-three" and the little owl is all there is of us. The editor forgot to put the little owl in the picture, and, worse still, forgot to put the picture in GLEANINGS. You see he got just the picture made without telling the Muser any thing about it, and the first the Muser knew it was done was after the former musings were all printed, when along comes a letter saying the editor wanted some kind of article with which the picture might appear; so here it is, and now you can see the Muser as you will

find him when he returns from the loft and the company of the owl.

September 2, 1896, we started on our overland journey. Baby Eva was eight months old when the photo was taken, and eleven months when we started on the trip. She now sits beside me as I write, fat and hearty, and busy helping mamma sew.

Our county, Larimer, lies on the north line of the State, just south of Cheyenne, Wyoming, and embraces a large territory, including a part of the mountains, and is probably 60 miles wide from north to south. Loveland is near the south line of the county, and is about 35 miles nearly east from Long's Peak, one of the highest mountain-tops. Our railroad is a part of the Union Pacific system, but now operated by the Denver and Gulf, and runs northward from Denver, and parallel

R. C. AIKIN AND FAMILY.

with the mountain range. The general course of the mountain range is nearly due north and south, and about every ten or twenty miles is a river or stream coming out of the mountains, all having a general eastward trend. To the north of us is the Poudre River, on which is Fort Collins, our county-seat,

a town of 2500 or 3000 population. Loveland is due south of Fort Collins 14 miles, on the Big Thompson River, and has a population of 1500. From Loveland we journeyed south 7 miles to Berthoud, on the Little Thompson River, and from there 10 miles south to Longmont, on the St. Vrain River, where we spent the night with Mr. J. B. Adams. Still south from Longmont is Boulder Creek and one or two more small creeks before we reach Denver on the South Platte River. From Loveland to Denver is about 50 miles—almost due south.

This territory, from Denver north about 75 miles, is perhaps the best-watered part of the State, and is a grain, hay, and stock country. The principal crop is wheat; second, hay; third, potatoes. The climate is alike throughout this region, but soil is very variable. Loveland has a clay soil, while Greeley, but 20 miles away, has a very sandy soil. Greeley is the center of the potato industry, and is famed for both quality and quantity of her "spuds."

There is also quite an industry in parts of the country in producing small fruits—principally strawberries and raspberries. Loveland, besides supplying her own market, ships large quantities of strawberries and raspberries. Apples, too, are largely planted, though but few orchards are in full bearing; but, judging from the results of the older orchards, and the great number of new ones started, I should say that, in ten years from now, there will be a big business in apples.

As alfalfa at present is the second crop—if not fully equaling wheat—we naturally find many bees throughout the country. Longmont and vicinity of Denver have probably more bees to the square mile than any other part of the State this side of the "range." The western slope, no doubt, has many bees too, though I doubt if any more than this region. In 1892 the number of colonies of bees in Boulder Co. was estimated at 18,000, which, yielding 25 pounds, would give 20 carloads. Outside of the towns, I should judge that one-fourth of the homes have from one to ten or more colonies of bees, and that within 75 miles of Denver there are bees enough to produce fifty or more carloads of honey, if they were properly handled.

All this country is watered by the aforementioned streams, and to take away these waters would be to lay desolate what is now a fruitful country.

So the first end of our trip was through this fertile, well-watered country going crosswise of the streams. We called on but four apiarists in going to Denver, because we were so late getting started that we could not visit much if we were to see all the country we had mapped out to traverse, and yet get to the Lincoln convention.

From Denver we continued south, passing through much barren country and some nice watered tracts, the greater part unwatered, till we reached the Arkansas River at Pueblo. Here and there we saw bees south of Denver, but they were scattering.

Denver is a nice city, but wretchedly wick-

ed; but the place of the greatest display of wealth was Colorado Springs. This is the place of residence of many of the mine-owners in the Cripple Creek district. Were it not for the mines I do not see how the place could survive, for the water-supply in that region is very limited, and very little farm produce raised. Colorado Springs must draw her supplies from other parts of the State.

You may wonder why the mine-owners should live in a town or city out of the mountains and many miles from the mines. I am not sure that I can give all the reasons, or even the principal ones; but the great elevation of the country where the mines are located makes the winter season extremely cold and disagreeable. Then, too, many can not stand a continuous residence at so great an altitude. The high altitudes are hard on heart and nerves. The writer finds his heart running about five beats per minute faster here than in the Missouri Valley, though not up to normal even here, 5000 feet. Could wife and I average the speed of our heart pulsations it would probably be better for both of us. The highest point we touched was at Palmer Lake, over 6000 feet, where wife said she did not want to stay long; but as for myself I felt no inconvenience whatever.

Pueblo is about 200 miles south of here, and from there we turned our faces eastward. The city seemed to be largely a manufacturing one, and a distributing-point for the mines.

*Continued.*

---

## MARKETING HONEY.

How the Home of the Honey-bees is Making Live Bees not only Gather Honey, but also Sell it.

BY A. B. WEED.

The subject of marketing honey is second in importance with the bee-keeper only to that of getting it. Much has been said about extending the market for it; but, as a usual thing, the suggestions went no further than to say, "Develop the home market." This is all very well so far as it goes; but the fact is, there never can be much demand for it where it is produced. The place to sell it is in the cities.

There are difficulties in pushing the honey trade, which do not exist in selling most other eatables. Sales are not often made by men who have an interest in it and who understand it, but by commission men. The charge of adulteration has been made so persistently that it is looked upon with suspicion. Then it has had to take its chances with other things which are put upon the market by men who know how to make their wares attractive.

This matter of suiting the trade, and tempting buyers, has grown to be a trade in itself. Almost every thing which is sold has the benefit of this kind of skill more than honey. The best way to increase the sale of any thing is to place it in an attractive form before the people who need it, and this is what the A. I. Root Co. have undertaken to do with honey.

A good display of honey was prepared, and with it some bees in an observatory hive to attract the attention of the crowd. It might be observed here that they are an excellent thing for this purpose, and the crowd which they draw will frequently reach to and even into the street. The first city in which it was shown was Akron, Ohio. This place was selected because conditions seemed to be favorable for a good market. The city was of good size—40,000—and, as most of the people worked in manufactories, they would have no one to spend. The venture was tried upon a very small scale at first, and two gross of one-pound glass jars were offered for sale. At first they went fast; but as the number of remaining ones grew less they did not seem to be noticed. But sales started up again as soon as more jars were put with them. The crowd which the bees drew seemed to overlook the honey unless there was enough of it to make a big show. This fact is a very important one, and should be observed by any one who tries to sell honey in this way.

Both comb and extracted honey were offered for sale, side by side, but the people preferred the latter. This seemed rather surprising, as the demand had always been the other way. The reason was that they had never before seen extracted honey which tempted them as much as this did, and they had always looked upon it with suspicion. But here was some that they had seen taken from the combs, and they had been made to understand why it could be sold cheaper than if the comb went with it. They now had confidence in it.

One of the most important things noticed about the enterprise was the fact that the honey was bought by all classes of people alike. Rich people bought it because it was pretty and tasted well, and poor people bought it because it was good and cheap.

In starting an enterprise of this kind the first thing to be considered is the fact that most people know but little of the apiary, although a few think they do. They have read that honey is adulterated, and that it is manufactured, and most of them are glad to meet some one who can really tell them the truth about it.

The most surprising thing, perhaps, about the business is the interest taken in it by city people. This is so great that it can be used by the dealer to bring his honey to their notice. Then if it looks attractive they will buy it; and if it is good they will like it, and the demand is established.

Every thing connected with the apiary is useful in getting their attention. Things which the bee-keeper is apt to overlook because so familiar with them are wanted as much as any thing else.

Any one who starts out to make a show of this kind must have a good stock of patience and breath. Many of the questions asked are intelligent ones, and these, of course, should receive attention; but very many are prompted only by curiosity. It is not always safe to give a perfectly truthful answer to such, because, the stream once started, there would be no ending. On this account it is some-

times best to obey the biblical injunction literally, and answer some people according to their folly.

One old gentleman, however, would not be put off in this way. He had never kept bees, never expected to, and had no reason for taking so much of my time. I finally said to him that I had told him all I knew, and handed him a copy of the A B C, directing him to learn it by heart; and then, if he felt the need of further instruction, come to Medina, the center of bee-knowledge, and the Root Co. would see what more they could do for him.

There is always at least one "smart" person in every crowd who knows just how strained honey is made, and can tell all about the way "comb is made of paraffine, filled, and then capped over with a hot iron." One of this kind explained the whole process to me lately, while the crowd listened and admired his wisdom. He did not know that I had any thing to do with the display. I thanked him for his information, and asked him if he believed what he said.

"Of course I believe what I say. Why do you ask such a question?"

"Because, my friend, I will show you a chance to make \$1000."

I then read him the offer made by A. I. Root, years ago, and which has not been taken up yet, and told him that Mr. Root was good for any amount. He subsided quickly, and backed out of the crowd. These cards are useful in many cases.

Another man was very positive about a few things pertaining to the hive, but not sure on other points. He knew that the workers laid all the eggs, that the queen ruled the hive, that the drones defended it from its enemies, but could not remember what the king bee was for! One man wanted to buy that "family" of bees and take them home in his trunk.

Here are some of the questions that I have fired at me every day. I have appended answers to a few of them, and perhaps the readers of GLEANINGS will help me with the rest.

"What kind of bees are those?"

"Those are live bees."

"Do bees die often?"

"No, only once."

"Do bees make honey?"

"No, neither do we. The bees gather it from flowers, and we take it from them."

"When do bees die?"

"When their time comes."

"Is the queen's sting poison, and will it kill you?"

"Why don't the drones sting?"

"Why don't you show us the king-bee?"

"How many bees in there?"

"How do you count them?"

"What do you use so that they won't sting you?"

"Were those bees wild once? and how did you tame them?"

"Ain't that drone there the daddy of them all?"

"Ain't they crowded in there? and don't the big ones hurt the little ones?"

"They look real sociable in there, so close together."

After one has heard such questions upward of a thousand times he begins to be tired; but after all, they show how much interest is taken in the subject by people who can easily be turned into honey-eaters.

One lady was heard to say to a friend, "That strained honey is a fraud. I bought some once, and it all went back to sugar. I was real careful of it, too, and kept it in the ice-box."

Such things show the ignorance with which we have to deal, and the need of popular education about honey.

Another lady said to me, "That honey," pointing to a glass jar of it, "is the nicest I ever saw." It was just like all other honey, except that it was put up in better style. Such things demonstrate the necessity of making it attractive. Only a few feet away there was an open box of one-pound tin cans of honey. Nothing had been done to bring it to the notice of buyers. No one bought it, and not many people even knew it was there.

There is one means of effecting sales which is particularly good, and ought not to be neglected. It is giving free samples. If you can succeed in getting a spoonful of honey into a person's mouth he will want more. I found that this bait would catch not less than five people out of six.

The honey used was California sage, and every one of the thousands who tasted it was very much pleased with it. Some other kind might have answered as well, but this it was which was used.

[I will explain to our readers that Mr. A. B. Weed is a brother of Mr. E. B., the foundation-man. For some time he has wanted to demonstrate that he could sell honey by making a show of live bees in a hive. When he told me his experience in that line, and how he drew crowds in the city of Detroit, I told him he might at least make an attempt. He prepared an exhibit, consisting of an observatory hive containing bees and a queen, some small cages containing each a queen, a few bees, and some drones. Along with this was an assortment of extracted honey put up in glass, an extractor, and comb honey in sections.

The experiment was tried first in our own town; but owing to the fact that everybody in Medina is familiar with bees it did not take as well as it did in Detroit. But still it helped materially the sale of honey in our local grocery, where the experiment was tried; and as Mr. Weed was desirous of trying it in another place, he prepared a similar exhibit for Akron, a city of about 40,000 inhabitants, about twenty miles east of here. As he explains, he took along two gross of jars (No. 25) of honey, and a can or two of California sage in bulk. The exhibit was made at one of the most prominent groceries, and the effect was instantaneous. Not only were crowds drawn, but honey began to sell in that grocery as it had never sold before. Mr. W. intended to stay only a week, because we were fearful the

experiment would not be a success; but at the end of that time he had cleaned out nearly all of our extracted mountain sage, and nearly all other odds and ends, and received instructions from Medina to keep right on. We now have a whole carload of beautiful mountain sage on the way, and we hope to be able to supply Mr. Weed with extracted honey of fine quality, to permit him to carry out his dreams that he has been incubating for several years, to make honey sell in groceries where it had been slow sale before.

When Mr. Weed calls on a grocer he asks simply for the privilege of space in a window, and stipulates that, for the first two days, he will make the display and sale of honey for him without charge. The groceryman makes all the sales, but is to buy the honey (of us, of course), and his profit will be the difference between wholesale and retail. In two or three instances Mr. Weed was requested to stay not only two days, but a whole week, at each grocery: and the way our women-folks have been busy putting up the extracted honey the past week or so shows pretty conclusively that the scheme is a success.

Live bees are indeed a real novelty to the average person. The habits of the interesting insects are briefly explained by Mr. Weed, the method of producing comb honey illustrated, and the *modus operandi* of extracting shown.

I omitted to state that, on top of the observatory hive, is put a row of sections of sealed comb honey. Mr. Weed explains how the comb honey is produced. He has also some extracting-combs filled with sealed honey. When he gets big crowds he extracts two or three combs to show how the job is done. This one fact alone inspires confidence in the consumer, and of course he not only buys what is real honey, but what he honestly believes to be a pure article.

Mr. Weed has another scheme. When the crowds will not buy he has on hand a lot of paper spoons—oblong strips of stiff paper about two inches long and an inch and a quarter wide. He curves one of these into a sort of trough, dips it into the thick mountain sage, and transfers it to his mouth. Handing out the "spoons" he invites the crowd to do likewise. Of course, there is a smacking of the lips (the spoon thrown away), and, "Um, um! that's good; I must take some home to my wife."

Perhaps it is a little late yet to make an exhibit of live bees, but we are doing it all the same, and I can assure you it is a great holiday attraction.—ED.]

#### SELLING HONEY DIRECT TO GROCERS.

Giving Commission Houses the Go-by; Selling Honey by the Piece Rather Than by Weight; a Racy and Interesting Article.

BY MORTON'S BROTHER-IN-LAW.

One day, about the first of October, Morton and I were busily scraping sections, and not sorry to see the end of that tedious task ap-

proaching. The summer had been fine, viewed from a bee-keeper's standpoint, and a good crop of comb honey was nearly ready for the market as a reward for time and labor expended. My thoughts had been running in the direction of a fishing-excursion now that a little leisure time seemed to be in sight, when Morton broke in with something like this:

"I am not sorry to see the last of this pesky scraping; but the tug of war is yet to come—the one part of the bee-business, and one of the most important parts too, which we bee-keepers don't seem to improve upon any. In fact, we go on from bad to worse; and that is to sell our honey after we get it."

"Well," I said, as he paused to lift over another super, "no one could expect you to sell it *before* you get it," which obviously sensible remark he disdained to notice, but continued:

"I can get honey ready for market in style that I am not ashamed of; take care of my bees all right, and even attend the conventions and picnics without flinching; but when it comes to selling the honey for a price which I am entitled to in all fairness for such nice honey as that lot is — why, I don't know how it is to be done. We producers keep sending our honey to the big cities, where the commission man sells it to a customer that he wishes to please *first*—the bee-man last. The dealer may be honest, of course; but the man who buys of him has the best of the situation every time. Then we send so much honey to two or three large cities that they are overstocked; the market is glutted; down go quotations; everybody who sells or buys honey governs himself accordingly; and after a hard summer's work we get it where the chicken got the ax;" and, going out to the grapevine, he picked the largest bunch of grapes he could reach, and went to see if the bees were all out of those last few supers over the escapes.

Said I to myself, "Who is this customer that the commission man is so anxious to please?" and the reply was easy enough—the retail grocer. He sells the great bulk of comb honey, without question. But how does the city commission house catch that retail grocer in the first place? By drumming the trade, sending out that knight of the grip, "talking like a blessed angel, eating like a blasted tramp."

"See here, Morton," said I, as he came in with a super full of sections, without a bee left in it (who would keep bees without using escapes, anyway?) "I've got a scheme."

"Don't doubt it," was his reply; "you never seem to be out of stock in that line," and he went after another super.

Such a little bluff as that never disturbs me. I'm used to 'em; and my thoughts cantered on in that same channel.

Now, if the grocer is to be patted on the back, his feathers smoothed the right way, why don't we honey-producers do it ourselves without paying any city commission man to do it for us? Isn't it the best way to please him, to so pack, grade, arrange in attractive shape, and, above all, give him a margin of profit, without any "unexplained residue of

facts" in shape of unsalable goods to make him wish he had never *seen* any honey? Morton had resumed scraping sections, and now wanted to know what my scheme was. To state it briefly, it was to skip the commission man in the city, and sell directly to the grocer.

We talked over the plan at length, and could see good reasons for and against; but, on the whole, we thought it would pay a trial; and after three seasons' successful sales you can put us down to vote in favor of the plan.

Our locality is about 300 miles from New York, with a dozen or more cities and towns between. What nonsense and waste to send our honey to the big city, pay freight, drayage, commissions, exchange stealings (?) drummers' wages and expenses, to come half way back and sell that same honey to the grocer!—more drayage, freight, etc., and the consumer must foot all these bills. On the other hand, the retail grocer seldom buys more than five or ten cases, and it is more trouble to take care of so many customers than the one commission man. The expense of going over the route with sample case is considerable, and bad debts are nearly always in evidence; but by selling some of our neighbors' honey (this year I sold for six apiaries), and dividing the expense, it brings it down to reasonable limits.

The next question was, "How shall we pack, grade, and advertise to best please our prospective victim, the grocer?" Morton and I were partners in the retail-grocery business for several years, and that experience helped us to some points, one of the most provoking of which is the ease and certainty with which a clerk will punch a big hole in one nice section of honey with the sharp corner of the one he is trying to put back in the case. Can't we fix something, some way, so that he can not do that? Sure! Slip veneers (or sliced separators) between the rows of sections in the shipping-case—they are good for nothing else, and cost but little (and have proved a drawing card with our customers). Always have new neat shipping-cases with the non-drip cleats in the bottom, *and* the veneers. So our grocer now has his case to retail from that is neat, tasty, handy, and convenient.

Next comes the grading; and again the memories of old-time grocery days put a "bee in my bonnet."

"How much do you ask for that honey?"

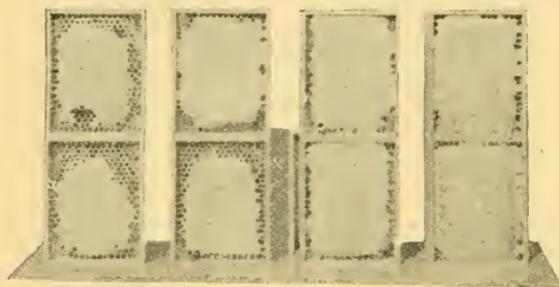

"Eighteen cents per pound, ma'am."

Let's see. Thirteen and a half ounces at eighteen cents per pound—um, um! Where did I lay that infernal leadpencil? um—um!

"Oh! call it fifteen cents," and then I wonder if my customer got cheated out of a fraction of a penny or whether I did. Then that last half-dozen unsalable sections, sure to show up where they pack all weights and styles in one case! The grocer's profits are right in that half-dozen. As the days go by, and the dust settles on them more and more, with more holes punched in them as they are handled over, the profits grow beautifully less. See? Why not do the square thing by that grocer, and put in all nice full well-sealed sections, so that there will be nothing left to drag on unsold at the last end of that case;

then put the culls (that's the word) in another case by themselves, and sell them at a "cull" price? More than that, as the sections are all alike why not sell them by count to the grocer? He is sure to sell them that way to his customers. In that way there are no awkward fractions to puzzle over. He buys for twelve. He sells for fifteen. Take your choice—the last section in the case will sell as well as the first. But, you may say, honey differs so much in weight, color, sealing, travel-stain, propolis-stain; and (referring to the printed grading-rules) bulged and crooked combs (which we don't have to contend with, for our cleated separators make the bees build their combs as straight as a darnin'-needle stuck in a board) that it would be an impossible job to accomplish.

The engraving shows how easy it is in actual practice. I put the six sections, shown at

NIVER'S FOUR GRADES OF HONEY.

the right on the shelf, in front of me. Picking up a section from the storage-case, a glance will generally show which grade it is. If any doubts exist, hold it near to the samples and give the lower grade the benefit of the doubt—that is, after packing, the goods should be better than the samples.

The two sections shown at the right of the engraving we name "Fancy" (fancy white, fancy mixed, fancy buckwheat, as the case may be). The next two we name "No. 1." The two next to "No. 1," toward the left hand, is "No. 2;" the remaining two are consigned to the extractor. The "No. 2" isn't fairly shown up by the picture. The lower one is very full weight, but poorly sealed. The upper one is sealed well, but is capped off short—making it light weight.

This plan of grading and selling has proved very satisfactory with us for the last three years, and we have upward of one hundred and fifty customers who express themselves highly pleased with the system.

One more knotty problem to solve before we can take the road with that neat-looking sample case, which is a half-section of a regular shipping-case; and that is—the price list. Three grades each, for three kinds of honey; nine styles to price according to actual value, instead of weight. The "fancy" must bring a relatively higher price (and are worth it) in order to bring up the average; for Nos. 1 and 2 must be cheap to sell at all. It is a matter

of judgment for each particular salesman to consider all the conditions of his market, and get as good a price for his goods as possible, and yet allow his friend the grocer to compete with anybody's else honey of equal quality.

Referring again to the grocer's side of the bargain, we know there are many varieties of 'em. Some grocers have a "toney" trade that demands only the best of every thing, and are willing to pay for it. We can just fit his case. That "fancy" brand was selected with an eye to capture his trade. The other dealer is situated differently—wants only cheap goods. "No. 2" is what fills his long-felt want. Now, notice! Haven't we got just what every buyer delights to find—a variety to select from? Doesn't that very consideration build up the enormous trade of the great city department stores, "because you can purchase there any thing, from a house and lot to a postmaster-general" — if you have the legal tender? But, my grip is packed, and the train is nearly due, and I am off after that friend of ours the retail grocer.

Groton, N. Y.

[It does indeed seem like poor policy to ship honey to a commission house, then in many cases have that same honey come back again almost to our very door. As friend Niver well remarks, why not save these two freights, and pocket the money yourself? Referring to the engraving and to Mr. Niver's method of grading, the reader will now see where I

got the idea of having photos of certain grades of honey to take the place of grading-rules, which so far have been unable to fill the bill, for the simple reason that language is totally inadequate to describe just exactly what fancy, No. 1, etc., should be. Unfortunately, the engraving herewith shown is not a good one, although it will illustrate somewhat the idea.—Ed.]

#### SOLID SEALED STORES FOR WINTERING.

Treating Foul Brood; The new Section and Cleated Separator.

BY F. A. GEMMILL.

It is not often that I write for GLEANINGS, nor, in fact, for any other journal. There are several reasons for this; the principal one, however, being my inability to furnish much of practical value that has not been contributed by others having more experience than myself. As, however, Dr. Miller, in *Stray Straws*, states as follows: "F. A. Gemmill, in *Can. Bee Journal*, says he has had success wintering on solid sealed stores, and quotes McEvoy as indorsing him;" and as Mr. E. R. Root has practiced putting such combs right into the center of the brood-nest, with success, I trust you will, if not already too well supplied with more important matter, find room for this effusion.

Well, I just want to state here what I briefly stated before, and will, therefore, give an extract from the article as it appeared in the journal referred to, which may not have been seen by the readers of GLEANINGS:

An ordinary-sized colony, in an eight-frame Langstroth hive, with from 25 to 30 lbs. of good sealed stores, can be successfully wintered outside, if perfectly packed, in my locality, without moving any of the eight frames. Of course, less stores will do if wintered in the cellar. But a fair or medium colony can be wintered splendidly on five solid sealed combs of honey or sugar syrup, with division-boards or dummies occupying the space of the removed combs. After the removal of three frames of empty comb, just put in three ordinary seven-eighths-thick division-boards in place of the combs taken out, and spaced in the same manner as if they were combs of honey, only they must be at the sides of the hive. Don't worry about the empty combs for the bees to cluster on. The insects will find room for that purpose if they require it, and will always have warm honey to eat when they want it. If you don't believe me, ask McEvoy. He is a good authority on almost every thing, including foul brood and politics. If you have a half-story of the Heddon hive containing sealed solid stores of honey, put a 2-inch rim under it, then shake out the bees from the same colony into this half of the divisible brood-chamber on or about the 15th of October, or even the first week in November, and then report how the bees wintered. I know it is a success with me, for I have many a time done it. McEvoy's plan and mine are alike, except that the clustering space is not located exactly in the same position in the hive. Try either or both, and judge for yourself. F. A. GEMMILL.

P. S.—The above plans refer more particularly to outside wintering.

Now, I am not the originator of the plan, nor do I know how many have followed such a practice; but I want to state emphatically that it was Mr. McEvoy who induced me to try his method, which he has practiced for about twenty years, so that it was he, and not myself, who deserves credit for the success I have had.

After becoming satisfied with the way things turned out I saw no reason why it should not succeed with other frames than the Langstroth, and consequently some six or seven years ago I shook the bees from 20 colonies on to a half-story of the new Heddon hive containing eight of those shallow sealed combs; and in order to provide for more room, should the occupants not be able to enter so small a dwelling, I placed a two-inch rim underneath each hive. Well, did they winter? Why, of course they did, in the very best shape, so that my success in this way was identical with Mr. McEvoy's.

To be sure, I am quite well aware *there are others* who differ with us, and think it is really a necessity to have empty combs for the bees to cluster on, etc.; and, if I mistake not, Mr. France winters in his quadruple hive on two sets of Langstroth frames, the upper story having sealed stores while the bottom story contains empty comb, which is removed in spring, leaving only one story containing the most until the colony becomes populous enough to require more room. If I am wrong, I hope Mr. France will correct me.

Mr. McEvoy claims that empty comb is a detriment rather than an advantage, as the cluster remains unbroken until the approach of spring; and, there being no brood-rearing at an unnecessary time, the bees winter better, and spring-dwindle less; in fact, they seem to boom right along when so prepared.

#### TREATING OR CURING FOUL BROOD.

The junior editor (E. R. R.) of GLEANINGS for Oct. 15 also gives instructions how to cure foul brood in the fall, and recommends that the bees be shaken on to foundation, and, after surviving long enough to be weak, or until the diseased honey they may have taken away with them is consumed, that two or three such colonies be dumped together into one hive, and then fed. I have not the slightest doubt that his advice is sound, and will effect a cure; but say, Mr. Root, why don't you try another of McEvoy's kinks, and just shake those bees on to five solid sealed combs of honey at once, and be done with it? Possibly you will smile at such a suggestion; but let me assure you that bees have been cured after this fashion, at this time of the year (October and November), and can be so treated again. Care, of course, must be taken that all the cells be sealed, and that the combs contain honey from sound or healthy colonies. There must be no half-doing the job, either.

Now you may probably say, "Oh, my! what about the honey the bees carry in their honey-sacs?" Well, there won't be much if you go about it properly; and what little is taken will be used long before brood-rearing is started; and there being no vacant cells to store it in can do no harm. Try it.

I will merely state, in regard to this foul-brood question, that, since the securing of legislation in Ontario, I have, in company with Mr. McEvoy, the inspector (I being the assistant), visited many diseased apiaries in the Province, and have seen many ways of curing the disease, all of which, in proper hands, will succeed; but as this article is now longer than I anticipated, and Mr. McEvoy having given his methods to the public already, I need not say more.

#### THE NEW SECTION AND CLEATED SEPARATOR.

I have carefully read all that has been written, both by E. R. and his father, on the above subject; and as you have assured us that the cost is not going to be a deterrent, and as I use the T super and section-holder, I am certainly going to give the *new old system* a good trial next season. I may say that I have thought some of doing the very thing you now recommend in this line, for three or four years past, but never managed to do it. I have, the past summer, given the Pettit system of using his divider, having the round perforations  $\frac{1}{8}$  and  $\frac{3}{8}$  of an inch, in conjunction with the wedges recommended by him for the production of comb honey, and found the outside sections were much better filled than when no divider was used.

I mention the fact of having used this system here, because Mr. Pettit preferred round perforations in his divider to having them made of several pieces with a continuous opening, as you illustrate the new separator in GLEANINGS. His reason for so doing was that he found the bees were more apt to draw out the surface of the comb and give the section, when finished, a ridgy appearance. It is quite possible, as you do not mention any thing of this nature occurring with those using

the separator you describe, that no marked defect in this line has been observed. Of course, if you were compelled to furnish them with round perforations the cost would be a serious obstacle to their use.

But I must conclude; for I fear that, if I continue much longer, I shall have to apologize for writing so long, much in the same manner that Mr. Abbott did for having talked so much at the Buffalo convention; viz., that I am almost beginning to hate to see myself write, as much as he did to hear himself talk.

Stratford, Ont., Canada, Nov. 12.

[I have great confidence in Mr. McEvoy; and if he says that dumping the diseased bees on sealed combs of honey does not next summer, or some time, cause the reappearance of the disease, then I am glad to acknowledge that his way is far shorter than mine, and that bees will stand a very much better chance of wintering.]

With regard to the fence, or cleft separator, our 1898 super, with plain section and a fence, will be so modified as to take in the Pettit idea; that is to say, there will not only be fences between each row of sections, but one on the outside of each outside row. This will in effect secure the same idea, only that the slots will be oblong and parallel, instead of round perforations, and I can not see why there should be any practical difference. What matters it to a bee whether the opening is square or round, so long as it can get through the same?

It is true, there will be "ridgy" comb honey if the slats are not pretty tolerably close together. Mr. Danzenbaker has found by experience that they should not be further apart than the width of ordinary perforated zinc, which, in round numbers, is about  $\frac{2}{3}$  of an inch. If further apart, it has been found in some instances that the surface of the combs will show ridges just opposite the openings; and it makes a difference, too, whether the slats are narrow or wide, if I am correctly informed.—ED.]

## PIPING OF QUEENS; HOW IT IS DONE.

BY E. S. ARWINE.

Mr. Editor and Dr. Miller, are you about to turn Turk? I see you have trotted out your horse-tails. You know the dignity of a Turkish pasha depends upon the number of tails the Sultan allows him to wear. In regard to the problem of how a queen pipes, I may not understand just what you term piping. I have heard only two sounds from queens. One is the note of defiance of a young queen just emerged from her cell, and is as definitely answered by her sisters who are about ready to emerge. These sounds always remind me of the descriptions I have read of tourney victor's bugle-note of challenge, and answered by any would-be contestant for the glories of the knightly ring. I have heard this note of defiance from young queens in the cells which I held in my hand, having removed them to prevent their destruction. Surely the wings

could not vibrate very freely in the cells. But this is more to the point. I was in the apiary, and heard this sound issuing from a hive; and on opening it I found a wingless queen. She had two little knots where the wings should have been. This little deformed creature was scurrying over the comb, uttering her war-cry vigorously. Certainly those little stubby wings could do very little vibrating. She had already executed all of her royal sisters but one on the outside comb, which hatched four days later. I dispatched her at once, but wished afterward I had let her live as a freak.

A balled queen utters another sound (a cry of distress), or a sound in a different key, which always sounds to my ear like a wail of agony; so I have no doubt that Cheshire is right, and speaks from his own observation.

### GRANULATION OF HONEY.

Below are tables showing the time of granulation of honey from various sources, as observed in three States:

#### INDIANA.

White clover granulated in 3 to 6 months.  
Basswood, or linden, granulated in 1 to 4 months.  
Fall honey from various sources granulated in 1 to 2 months.

#### TEXAS.

Persimmon (April) granulated in 2 to 10 days.  
Honey-locust (May) granulated in 2½ to 3 years.  
Horse-mint (June) granulated in 3 to 8 months.  
Chittim (July) granulated in 3 to 10 months.  
Cotton (July to October) granulated in 3 to 5 months.

The words in parenthesis show time of secreting. The secretion of honey by the persimmon-tree lasts about 10 or 12 days, and granulating always began before the honey was capped over. All the persimmon honey I ever took came from the wild persimmon-trees in Texas.

#### CALIFORNIA.

Sage, black and white, balled or buttoned, 3 to 12 m.  
Sage, white (spiced or racemed) 3 to 12 m.  
Barberry (pure) remains liquid indefinitely.  
Barberry, mixed with sage or other honey, 1 to 2 yrs.  
Tarweed (a species of aster) 20 to 40 days.

Tarweed honey granulates in the combs in from 30 to 60 days.

There are various other early honeys, such as manzanita and wild currant (January and February); live-oak (February and March); buckthorn and wild gooseberry (March and April); poison oak, or ivy (March to May). The manzanita and poison oak sometimes secrete honey very bountifully; also honey-dew (aphis honey) (August to November).

I have never kept any of the very early and late honeys to see how long they would be in granulating. Any honey extracted green (persimmon and tarweed, and possibly alfalfa, excepted) will granulate much earlier than well-ripened honey from the same source. Persimmon honey must be extracted green to get it in the liquid state. Sage honey, if left on the hive, will remain liquid indefinitely, but will become so thick and tenacious that but very little of it can be extracted without destroying the combs. I have never kept white-clover, honey-locust, horse-mint, chittim, sage, or barberry honey in the sections until granulating occurred. I very much doubt whether Texas honey-locust, California

sage, and barberry honeys would ever granulate if left three or four months on the hive after capping was completed.

Sage honey left in the hive ten months becomes so thick and tenacious that it will string out like soft wax, but show no indication of granules.

Dove, Cal.

### RAISING QUEENS ON A STICK.

Doolittle's Method a Great Success; a Few Valuable Hints for Queen-breeders.

BY A. E. DEWAR.

The May numbers of GLEANINGS have just reached me, and I feel that I must "line up" and support my friend H. L. Jones in his remarks on the value of the "New Method of Queen-rearing."

In January last I visited the Mel Bonum Apiary, and Mr. Jones then described to me his method of utilizing drone comb for queen-cells; and although I admit that a saving in time is effected, yet, after trial, I still prefer Mr. Doolittle's plan.

I am sending you a photo showing fair average results secured, and method of procedure, which I will describe briefly. After making cells as instructed by Doolittle, insert a small quantity of royal jelly. A larva from a selected breeder is then transferred with a single stick made from a piece of section, thick at one end, to break down walls of cells, and quill-shaped at the other to lift larvae. The frame to which they are attached is then given to the top story of a strong colony containing a queen confined under a double honey-board. Such colony is utilized right through the season for this purpose; a plentiful supply of hatching brood is given to regu-

larly, with the result that about 90 per cent of the cells are accepted, and well and evenly developed. Should the honey-flow cease temporarily the colony is fed liberally.

I really can not understand how any one who has a large demand for queens could resort to the old style, as there are so many advantages in using artificial cells. The necessity of mutilating good worker-brood comb is overcome, and a considerable amount of time is saved, as, by keeping a proper register, the cells can be found without overhauling all the frame of the colony, and they can be left severely alone till at least the tenth day from starting. I generally use 18 to 20 cells on each frame, but have had as many as 27 accepted in one lot. I am living about 200 miles further north than Mr. Jones, but I do not think the climate has much effect on the result so long

RAISING QUEENS BY THE DOOLITTLE PLAN.

as the colonies are strong with a plentiful supply of young bees, and a fair flow of honey.

The frame in the foreground of photo shows 16 well-developed cells just ready to hatch, and they will be distributed in various nuclei, and its place will be taken by a frame with a new supply of cells, and so the process is repeated. Queens raised by me have taken

all the prizes offered at local shows during the past five years. Some 14,000 lbs. of honey, from 50 colonies, proves that they are bled for business as well as beauty.

#### MAILING QUEENS.

On page 335, May 1, I agree entirely with your remarks about comb honey being appreciated by bees when passing through the mails, and I hope you will continue to experiment in that line. During the past two seasons I have had eight queens from you and Doolittle; and although they were all dead I noticed that in each case the whole of the comb honey was consumed, and in one the queen was buried in the cells. Evidently her last effort had been to obtain more honey, and she died in the attempt.

I have come to the conclusion that the ventilation is of more vital importance than feed. The variation from 100° and higher, when crossing the equator, requires to be provided for as well as a probable 40° before leaving your continent. Try again.

North Rockhampton, Queensland, Aus.

#### BEEs FREEZING TO DEATH

*Question.*—I have five colonies of bees this fall, and wish to know, through the columns of GLEANINGS, whether there is any danger of their being frozen to death if I leave them outdoors, where the mercury sinks as low as thirty degrees below zero some winters. I am told that bees often freeze to death in this cold climate; and if such is the case, I fear I may not be able to winter them.

*Answer.*—People often say to me, "Don't your bees freeze to death out here in the cold all winter?" and I sometimes read in agricultural papers about bees freezing to death; but I always consider such talk as fallacious when it is spoken of in connection with a full colony of bees. Individual bees, or even a cluster of from fifty to one hundred, when separated from the main cluster, often freeze to death, the isolated individual bee always succumbing to the cold with a temperature lower than forty above zero, unless it warms up within 36 hours after the bee ceases to move; but a good colony of bees, in a good hive, with plenty of stores at their command, never dies from cold in a sense that can in any way be interpreted that they froze to death. If we investigate this matter we shall find that, while it is possible to freeze nearly all animal life by exposure to a very low temperature, the bees seem capable, with plenty of stores near at hand, to stand any amount of cold, so long as food remains within easy reach. To be sure, the bees on the outside of the cluster may become somewhat stiffened with cold; but those within are nearly as brisk and lively as in summer. The lamented M. Quinby, whose authority is

rarely ever questioned, knew this to be a fact when he said that the bees inside the cluster, on a zero morning, could fly as readily as in July, should the cluster be suddenly thrown apart. Then Elisha Gallup, who gave us so many excellent articles on bees during the latter sixties and early seventies, speaking of a winter in Upper Canada, says, "The thermometer for sixty days in succession was not above 10° below zero, and for eight of these days the mercury was frozen; yet my bees, in box hives, with a two-inch hole at the top, and the bottom plastered up tight, came through in excellent condition." See *American Bee Journal*, Vol. 5, page 33. While bees here in Central New York were never put to so severe a test as that, yet I have it recorded in my diary where the mercury went as low as 30° below zero one winter and as low as 25° below several times; yet, so far as I could see, the bees did not materially suffer from this extreme cold. From experiments conducted with a self-registering thermometer during several winters I have found that, with a temperature of 20° below zero in the outside air, a temperature of 45 to 46 degrees above is maintained within the hive, with the bulb of the thermometer touching the outside bees of the cluster, while an equal number of experiments with the thermometer placed in the center of the cluster of bees gave a warmth of from 63 to 64 degrees above zero, when it was from 10 to 25 below outside; thus showing that the inside bees of the cluster were very far from freezing. To test this matter more thoroughly, and prove the thing beyond doubt, I took a colony one evening, when the mercury stood at ten below zero, and suspended the hive about two feet from the bottom-board, taking off all covering from the top of the hive, so they were the same as if hung in the open air, so far as bottom and top were concerned; and as the bees did not come out so as to touch the hive in any place, they were very nearly so at the sides. They were left thus all night, during which the mercury had gone as low as sixteen below zero, yet the next morning the bees were all right, although the cluster had contracted till it was little more than half as large as it was the night before. Had they been thus left till they had consumed all the stores inside the cluster, undoubtedly they would have succumbed to the cold; but in that event it would not be a case of freezing to death, but of starving; while the freezing came in as an after-consideration.

Since trying these experiments I have come to the conclusion that the freezing of bees, when in a normal condition, is an impossibility, and that all talk about such freezing is merely idle vaporings, and that the finding of bees dead and frozen only gave proof that the freezing was an effect coming after death, produced by some other cause than cold, such as starvation, bee-diarrhœa produced by long confinement, etc.

This talk about full colonies freezing to death reminds me of the story about the poor church that wanted some hymn-books. They needed the books badly, but did not know

where the money to purchase them was to come from. So they called a meeting and instructed the clerk to write to all the book firms whose address he could find, for lowest prices on fifty books; then he adjourned the meeting for two weeks till a reply could be gotten. At the appointed time they came together to hear the result, which was that 50 cents each, or \$25.00 for the lot, was the best that could be done, with one exception. That exception offered them the books for five cents each, or \$2.50 for the lot of fifty books providing they would take books having a few advertisements in them. The matter was talked over, and it was thought that a few advertisements in the back part of the book (as we often see on the covers of our Sunday-school lesson-helps) would do no particular harm, so they instructed the clerk to order the five-cent books. He did so. It so happened that Christmas came on Sunday that year, and the hymn-books arrived late Saturday night. The sexton carried them to the church, and hurriedly distributed them among the pews, having no time to look at them. The congregation arrived; and the pastor, arising in the pulpit, said that, as it was Christmas morning, it would be appropriate to begin their sabbath worship by singing the hymn commencing with "Hark! the herald angels sing," etc., and read the first line to the hymn from his own book, and sat down. The chorister struck up, and their surprise and consternation can be imagined when they found themselves singing:

Hark! the herald angels sing!  
Beecham's pills are just the thing;  
Always sure and very mild,  
Two for man and one for child.

So with some people who would instruct along the line of bee-keeping pursuits; they suppose they are singing the truth, when afterward it proves to be only advertising for themselves, or idle vaporings of their imagination, or something they have heard in the gossip at the "corner grocery."

[At the time I called on friend Doolittle, and just before leaving, I said to him that I wished he would sprinkle some of the good stories, that he had given us in his convention talks, into his regular articles for print. He hesitated somewhat, saying that he could feel the pulse of an *audience*, but could not determine the mood of *readers*, whom he could not see, and for that reason he was afraid to venture. I told him to have no fears on that score—to sprinkle in the salt and spice just the same whenever they would flavor a dish of dry facts. He did not give me a decided answer that day; but a few days ago he sent the article above, and along with it a private note, in which he said, referring to the anecdote, "When it is written on cold paper it seems stale, and unworthy of a place in a sober article on bees; so I leave it to you to put it in print or to leave it out, as it seems good in your sight. If you publish it, and it takes, I can give more." Yes, indeed, give us more, friend D. Our Borodino bee-keeper speaks in a clear, strong voice; he is a large man (large in two senses) and the enthusiasm that he

throws into his talks is accompanied by a captivating sparkle of the eyes and this sort of personality may, in some cases, make some of his stories sound better than they read, but I have no doubt that they will all read well.—  
Ed.]

I live in Richmond, Va. I don't suppose we have as strong a honey-harvest as our brothers further north, and not so long a one as our brothers in the far South, so I should like to ask a few questions:

1. Do you think it will pay to run the business near this place?
2. Will bees store as much honey in large one-story hives as in two story?
3. Can a strong colony of bees store enough in a one-story eight-frame hive to carry them through the winter and raise brood enough to keep strong?
4. Can I keep a queen all winter with a pint of bees, on three frames of combs, and raise a large colony if I feed well? and must I give them any thing else except syrup? If so, what else? Must I feed any thing for pollen? If so what?
5. What is the best way to winter queens?
6. Can you winter two queens in one hive with a queen excluder between them?
7. Can you extract honey from brood-frames without hurting the young brood?
8. Will the extra-light section foundation work all right in brood-frames if wired?
9. Will bees work as well with frames cross-wise as they will from front to back?

VIRGINIA.

- [1. I think it would.
2. Not as a general rule. In localities where the season is short and the flow moderate, the single-story hive would probably give better results—that is to say, secure all the honey at less expense than the two story; but in localities where there is a long honey-flow, the two-story would do better for a certain length of time.
3. Yes, if they do not use it up in the fall, before winter sets in. If you have a late flow from buckwheat or some other good source, then if the colony fills its hive it will have a great plenty for winter. But an eight-frame hive full of honey by the middle of July, with no further honey-flows, would require to be fed, probably, in the fall in order to give the requisite amount of stores.
4. Yes, if you are skillful enough; but do not give them any thing but good granulated-sugar syrup.
5. The best way to winter queens is in strong colonies, in hives properly supplied with stores, and, if outdoors, in double-walled hives packed with chaff, planer-shavings, or sawdust.
6. Not as a general rule. I should expect

war in that family very shortly. Two queens in one hive, under average conditions, do not get along any better than two bosses in a shop or two cooks in a kitchen.

7. Yes, but it is not advisable. The best practice is to let combs containing brood entirely alone so far as extracting is concerned.

8. Yes and no. If a narrow starter is used it would do without wires. It would also answer in full sheets providing the wires were put close enough together, say about one inch apart; but as a general rule it is cheaper and more practicable to use ordinary brood foundation, such as is made for the purpose; and then the combs, when drawn out will be none too strong, even when built over wires.

9. Some bee-keepers think not; but, so far as I am able to judge, those bee-keepers who use frames crosswise produce just as much honey as those who use frames the other way of the brood nest. It is only a question of convenience. The frames that are used crosswise are shorter, smaller, and, consequently, there are more of them to handle.—ED.]

#### WAX PRODUCTION; IS IT PROFITABLE? WING-CLIPPING; HOW TO FIND QUEENS IN LARGE COLONIES.

1. How is an apiary run to secure a large amount of wax?

2. Does this pay better than honey?

3. Is spring or fall the best time to clip queens' wings?

4. What is the easiest way of finding the queen in hives that are just running over with bees?

E. O. H.

Philadelphia, Nov. 10.

[1, 2. The production of wax alone is not profitable except in localities where the honey-flow is continuous almost the whole year round, and the honey is cheap and wax expensive, as for instance in Mexico or the West Indies. I should not know exactly how to proceed in running for wax alone; but my notion would be to cut out the combs every few days, and put them in a solar wax-extractor. The honey settling to the bottom could be drawn off and given to the bees again; and the wax forming at the top could be set aside in irregular chunks until enough were secured to cake them in pieces suitable for market.

3. There is not much difference. Wing-clipping should usually be avoided when colonies are strong; and that operation should usually be performed either in the spring or fall—generally in the spring, for then the apiarist is sure of having the wing clipped *before* the swarming season comes on. At our outward last summer, in the case of some of our strong colonies with unclipped queens, I simply put on entrance-guards.

4. There is no easy way that I know of. Many a time have I hunted through populous colonies to find a queen whose wings were not clipped, and whose bees were pretty nearly ready to swarm. In some instances these colonies were some we purchased, and, of course, the queens' wings had not been clipped. In any case it is my practice, if I do not find the queen the first two times in looking over the

frames, to shut the hive up, then in two hours more I take another look. If I *still* fail to find her, I remove the whole stand and put another hive in its place. At the entrance of the new hive I place perforated zinc; after which I shake the bees out in front of the hive on the ground, compelling them all to pass through the zinc. If there is a queen in that hive, and she is not too small, she is sure to be caught. I have had to do this in a few instances with black bees. It is a characteristic of these bees that they will boil over, and run like a flock of sheep from one frame to another; and the queens hiding—why, they are adepts at it. When I take the time to try to find a black queen, I want two pairs of eyes so that both sides of the comb can be seen at once.—ED.]

#### LARGE ENTRANCES.

I had two new ten-frame L. hives with every frame filled with foundation. A large double swarm was hived in each of these hives the last week of June. The D. bottom-boards were turned over, giving the winter entrance. Then the hives were raised  $\frac{3}{8}$  inch by small blocks under the front corners and a strip under the back, giving  $\frac{3}{8}$  inch each side, and  $1\frac{3}{8}$  inches in front. Results—no lying outside, and busy work every day when possible. The bees were packed down solid to the bottom-board, and at no time could I look from one side of the hive to the other side under the frames. There was always a bridge for them to climb on to the frames, but no comb was built in this space. When the hot weather was over, the board was inverted, giving them an entrance only in front. The season proved to be a poor one; but these two swarms gave me over 70 lbs. surplus, of which about half was extracted. Each hive was supplied with two supers. Give me large swarms and large entrances, with shade. J. L. HUBBARD.

Hendersonville, N. C., Nov. 11.

#### LARGE ENTRANCES; GOOD RESULTS SECURED BY THEIR USE.

I have thought for years that a hive-entrance  $\frac{3}{8}$  x 6 or 8 inches was too small, both summer and winter; and after studying a long time I changed a lot of my chaff-hive entrances last winter for use this past season. With keyhole-saw I cut a strip  $1\frac{1}{4}$  in. wide the whole width of inside,  $14\frac{1}{4}$ ; and as my old entrance had a slide held in place with metal springs I have the two combined, so, if need be, I can use the small one and regulate it down to one bee or none.

I fitted in stays between the two thicknesses (outside and inside) to make even work. A full entrance of this large size is too much some of the seasons, say in dearth of honey, as the robbers would take advantage. But if no small entrance is provided, one end of the block can be inserted, and regulate the size in that way.

I never did a thing that seems so useful. There isn't that lot of bees fanning to keep cool, and great clusters of bees on the outside of the hives as before; and I never had bees work as these have through the large entrance.

In addition to this I've made rims  $1\frac{1}{2}$  in. high, and wide enough to take 8 L-spaced frames, the same extended out to fit against the inside of the front and back of my chaff hive, and just the same length inside as the common inside or lower story. Now I have raised my frames and bees, and put a rim under, so there is a  $1\frac{1}{2}$ -in. space under the bottom of the frames. Thus I can easily clean out dead bees when in the cellar in winter, and shall use more packing over the bees than usual. You see the division-boards can be used the same, and the packing makes all neat and snug. It seems to me you would do a good thing by adopting something of this kind.

E. P. CHURCHILL.

Hallowell, Me., Oct. 18.

[Any one who will use a large entrance in summer can't fail to come to the same conclusion you have. How stupid we have been all these years, compelling the bees to use a poorly ventilated hive, and crowd and tumble over each other in order to get into a hive during the height of the flow.—ED.]

#### THE NEW FENCE AND THE PETTIT SYSTEM.

I too am very much interested in the new style of separator and section. As I understand it, the separators are to be made of narrow strips, with narrow spaces between. Referring to GLEANINGS for Jan. 15, 1897, page 52, top of right-hand column, Mr. S. T. Pettit says: "Dividers made of slats  $\frac{1}{4}$  inch apart leave the sections ridgy, reminding one of a miniature washboard." This he obviated by boring the divider full of  $\frac{1}{16}$ -inch holes instead of leaving the  $\frac{1}{4}$ -inch spaces. Now, would there not be the same trouble in the new separators? Has any one tried, during the past season, the plan advocated by Mr. Pettit in the same article, commencing on page 51, entitled "A new system of taking comb honey; how to get the bees to fill the outside sections as quickly and as nicely as those in the center of the super"? If so, I should like to hear the results, and also how Mr. Pettit himself has succeeded on that line the past season. It seems to me this idea, taken in connection with the no-bee-way sections, might make quite a difference in the crop of nice comb honey, especially here in the East, where in many sections the honey-flow is not as copious as further west, and we need to use every means to secure all the honey our bees are capable of gathering, and secure it in the best possible condition.

Natick, Mass.

R. J. FOX.

[See answer to F. A. Gemmill, page 846 this issue.—ED.]

#### NO-BEE-SPACE SECTIONS FAVORED.

*Mr. Root.*—I see you wish to hear from those who have used sections with no bee-space. I have used about a thousand of this kind this season, and I like them so well that I will change all my supers to take this kind. All you say about their better appearance is true. I used cleats on the separators  $\frac{1}{8} \times \frac{1}{4}$ , but this is hardly wide enough or thick enough.

They should be  $\frac{5}{16}$  wide, and a little more than  $\frac{1}{8}$  thick. It will require very careful measurements to get them just right; for if they should be a little too thick there would be trouble about crating. I find they will bulge out the combs a little just below the separator. I use plain separators  $3\frac{1}{2}$  inches wide. I have not tried slotted separators, but believe they would be better.

There is only one fault that I have found in using this arrangement; and that is, in cleating the separators they *must* be put on accurately. I use  $\frac{1}{2}$ -in. wire nails, driving them clear through, and clinching them. Glue would perhaps be better and quicker.

W. C. GATHRIGHT.

Dona Ana, New Mex., Oct. 30.

[The fences we shall make and sell will be put together with automatic machinery, and will have to be just right. Yes, if the slats are too far apart the combs will be ridgy every time. See answer in this issue to F. A. Gemmill, on page 846.—ED.]

#### THE DEEP-CELL FOUNDATION A SUCCESS.

Last spring you sent me samples of deep-cell foundation. These I placed in sections, putting two sections into supers with some partially drawn combs and some thin foundation starters. In every case the deep-cell foundation was the first to be worked on, and in one super those two sections were the only ones properly filled, others varying from nothing to  $\frac{3}{4}$  full. Deep-cell foundation suits me well in this year's trial.

L. D. STILSON.

York, Neb., Nov. 10.

#### HONEY RUINED BY SOOT.

Honey is a failure here. This is a manufacturing town, and the soot ruins all the honey for miles. Owing to the continued dry weather this year we shall not be able to send you any seed.

D. L. MURFF.

Anniston, Ala., Oct. 28.

[It has been before stated that honey-producing in a manufacturing town where there is a large amount of smoke is unprofitable. It seems a little hard to believe that soot could prevent the blossoms from yielding nectar, but it may be true. I'd like to have reports from others.—ED.]

#### THE FLORA ON THE COAST OF SOUTH CAROLINA.

In reply to query by "East Coast," page 739, I beg leave to say that, while we are rather outside of the limit—a little more than 100 miles from the coast—I will give enough information to provoke further correspondence.

We are told that in portions of Eastern North Carolina (in the swamp region) bees do well. We much prefer to speak of the territory west of this, Charlotte, N. C., 100 miles, or along the eastern slope of the Blue Ridge range, where we have fine bee-pasture. The poplar (tulip), holly-locust, and fruit-trees furnish the early or May crop. June brings linn, persimmon, and redwood, while the sour-

wood and other minor sources furnish the July crop. It was the writer's pleasure to spend five weeks, in 1895, prospecting in this favored locality.

A mountain location is, in my judgment, the only safe one, owing to its unlimited forests too rough to be visited by the ax or plow.

Here we get fair yields, but of an inferior quality. Ours is a cultivated field—no forests. Cotton and the asters give our best crops.

Prices are better than north or east. We get 8 and 9 cts. for extracted in a jobbing way. Four cents was C. F. Muth's best offer for our product. The tulip furnishes the only dark honey in our mountains. A. L. BEACH.

Steel Creek, N. C., Nov. 10.

#### DEATH OF A GREAT BEE-KEEPER.

I was struck, on opening the local paper this morning, to read of the death of Mr. Bonnier Georges de Layens, 63 years old. I hastened, when I went to France, to make the acquaintance of the now departed eminent French bee-keeper. He died on the 23d of October, of an apopleptic stroke. The struggle lasted about seven hours. He did not regain consciousness. His hive is well known all over France, where it has always had to compete with Charles Dadant's. The latter finally has the preference. De Layens came here to gather some more flowers to complete his "Flora," of which several editions are already out. He was born in Lille on the 6th of January, 1834. His features were not changed at all. His body will be taken to Paris, to the family tomb, as he was only temporarily here. PH. J. BALDENSPERGER.

Nice, France, Oct. 24.

#### MOVING TO GET MORE PASTURE; NEIGHBORS' BEES.

Bees have done well this season; but in order to get a good honey yield I had to move most of them two miles to fall blossoms. My home yard is overcrowded on account of neighbors' bees. I got 2000 lbs. of comb honey from 35 colonies, in two months, besides about 300 lbs. extracted from unfinished sections. It paid me to move them, you see

Filion, Mich., Nov. 16. I. S. TILT.

This was the best honey season we have had for quite a time. From 20 hives I took 1400 lbs. in sections, and now have 50, all from the 20, spring count. I have sold all this honey around home. J. E. HENDERSON.

Elm Grove, W. Va., Nov. 4.

How doth the little busy bee  
Improve each shining hour  
In gathering honey all the day  
From every opening flower!

But this is the way it has recently been paraphrased in one of the great dailies. Besides a little mixture of gender, there is a little contradiction of facts:

How doth the little busy bee  
Delight to bark and bite!  
He gathers beeswax all the day,  
But his sting is out of sight.

*T. W. M., Ill.*—It is too late to stimulate brood-rearing. You had better unite your weak colonies, as you suggest. For particulars in regard to uniting, see our A B C of Bee Culture.

*E. C. R., Ind.*—I would not advise you to buy bees at this time of the year, unless you can get them at a bargain, and have had sufficient experience to enable you to winter bees successfully. It is already too late to do much in feeding them up as they require.

*M. S. G., Wis.*—Tared paper used in the construction of a building will not in any way injure or affect bees. Our house apiary, illustrated and described in our A B C of Bee Culture, is lined on the inside with tared paper; but we never could see that it was in any way obnoxious to the bees.

*A. B., Ohio.*—I see no reason at all why you could not move your bees in a wagon without springs, providing you put hay or straw in the bottom, as you suggest. Of course, you would need to drive more carefully and more slowly; but we have moved bees several times successfully in just such a wagon.

*F. P., N. Y.*—Yours of Nov. 5 is at hand, stating you have a furnace in one compartment of your cellar, and that the other part is separated off by a board partition. If you can keep the temperature in this part of the cellar as low as 40 or 45 degrees, certainly not higher than 50 during the greater part of the winter, I think you can winter bees there all right. The temperature should not go below 40 degrees, at least for any great length of time.

*J. H. H., La.*—We usually figure on about 10 pounds of honey per Langstroth frame—frames that are fairly well filled with honey, while 25 pounds of honey, scattered through three or four frames, is enough to carry the bees safely through the winter. If you have four or five combs fairly well filled with honey, leave them in the hive. It will be all the better for the bees next spring.

Your idea is all right; namely, to give your surplus combs to other colonies that may need it that are short of stores. This is the practice that is usually pursued by bee-keepers generally.

*J. J. V., Mo.*—I understand now what you mean by the controller. This, as I understand it, is only the Langdon non-swarm over which, a few years ago, bee-keepers were very enthusiastic, but which now has been abandoned as impracticable, and as not carrying out the expectations of its friends. We sold them one season, but finally discontinued selling them, as reports showed it did not work as expected. I should judge that the

leaf from the catalog is from an old one that is not now issued by the party in question.

*L. E. B., Mass.*—If I understand your question, you desire to know how many acres it would take to support 1000 colonies. It would be impossible to give you any definite answer, because so much would depend upon conditions and circumstances; but the average locality in the North will not support much over 100 colonies, and such an apiary ought to have a range of a radius of about 1½ miles. Theoretically, another hundred colonies should be in another circle just touching the first one, the second circle being also three miles across, and another circle of the same size just touching the two circles already mentioned, and so on. You will find this question fully discussed in our A B C of Bee Culture, under the heading of "Out-apiaries."

*W. H. L., Mich.*—1. Is the odor of coal-tar disagreeable to bees? [Not to any appreciable extent.] 2. Would they reject a hive if the bottom-board were painted with coal-tar on both sides and the edges? [No.] 3. Would the odor of coal-tar taint honey perceptibly? [It probably would if the honey were stored in barrels smeared inside with coal-tar.]

In our last issue I took so much space that I will take but very little this time, and give the space to our correspondents. In our next issue I hope to begin again my trip among bee-keepers.

GLEANINGS can be very truthfully called an illustrated bee-journal. While it makes no pretension of competing with the illustrated magazines of the day, it simply attempts to show kinks and ideas by means of pictures rather than by language, which is very often inadequate.

It does not seem to be generally understood yet that the new fence (cleated separator), and plain section (no bee-way), can be used in old-style T supers and section-holders, the same as the old section. In the case of the section-holder the cleats on the fence, together with the plain section, make exactly 1¾ inch. The only change necessary is to purchase fences. If you do not see how it will come out, send us 10 cts. and we will send you a sample fence with section, which, when you have tried in your super, you will see it will come out "slust the fit," as Rambler says. You will need to tell us in ordering a sample what style of super it is to be used in—T super, or section-holder arrangement.

*The Agricultural Gazette*, of New South Wales, for September, 1897, issued by the Dept of Agriculture, Sydney, Aus., contains

an article on the influence of bees on crops, by Albert Gale. The writer shows quite conclusively the important bearing that bees have in mingling pollen from plant to plant. To quote him, he says:

I think I have pointed out clearly that there is no insect so highly developed for carrying the imperatively essential pollen from flower to flower as the hive bee. Their intelligence, their energy, their social habits and the ease with which they are kept under control, stamp them at once as no mean ally to the tiller of the soil. The practical bee-keeper in any district is a confederate that should be welcome to all.

It is to be hoped that the whole series of articles on this subject, by Mr. Gale, may be put in pamphlet form for free distribution, as they form a very comprehensive examination of this subject.

#### SOMETHING NEW UNDER THE SUN.

YES, I have found something absolutely *new* in bee-literature. So novel and original is it that I am going to present a few paragraphs from an article entitled "The Life and Battles of Bees," by George E. Walsh, published in the *Chautauquan* for September. The writer sets forth in flowing English some of the conflicts the bees have among themselves. "Uniting," he says, "while understood by the modern bee-keeper, is a very difficult operation, and has been accomplished only after long experience and many failures; for the natural antipathies of the members of the two flocks are such as to prevent association except under extraordinary conditions." And then, in speaking of the ordinary Italian bees and the black bees of the woods he gives us this piece of information: "The hostility between the wild bees and the domesticated colony will not permit them to unite."

Now listen to this, for he is going to tell us something we never knew before—how it is that bees can recognize robbers. Just read:

At the entrance of every well-filled hive several sentinels will be found lingering, and upon the appearance of a bee they challenge it. One of the sentinels extends its tongue; and if the new comer belongs to the colony it will answer by proffering a sample of its honey; but if the bee should prove to be an intruder the sentinels pounce upon it immediately and sting it to death. Occasionally a stray bee will attempt to obtain entrance into a well-filled hive in this way, and it will offer a sample of the nectar from its honey-sac; but the wary sentinels are not so ten deceived, and the intruding bee pays the penalty of its temerity.

Here again is another sample:

Inside the hive, breast-works and fortifications are constructed, tier upon tier, and the attacking forces are compelled to pass through holes and narrow cuts.

The writer now goes on to tell about the condition of queenless colonies. He says, and very truly, that there will be small protuberances like peanuts sticking out of the combs; and if these are unmolested a queen will hatch. So far we all agree with him; but now read what he says regarding the philosophy of introducing by the modern candy method:

But now a queen-bee from the South or an imported Italian queen is obtained and introduced in one of the modern queen-cages. So closely imitated is the ordinary cell of a queen-bee by this cage that the hive workers are readily deceived. The cork is removed from the small cage, and the opening smeared over with sugar paste. When this is carefully inserted in the hive, on top of the frames, over the cluster, the bees will instantly pounce upon it and liberate the

queen by eating through the sugar paste. Poor deluded souls! in their innocence they think they have hatched out a queen to take the place of their dead one, and there is undoubtedly great rejoicing in the hive.

Poor deluded souls, indeed! Mr. Walsh's great heart of sympathy is sublime. There are several other statements that do not smack of real experience, but I will give only one more on this wind-up of the article.

It should be remembered that bees deserve our respect and protection, and that to kill a bee is to waste a pound of honey.

A bee worth a pound of honey! Would it were so! If it were, a colony that produced 50 lbs. of honey would contain just 50 bees. Whew!

I am surprised that the editors of the *Chautauquan* did not recognize the absurdity of some of the preposterous statements, even though they were not professional bee-keepers. Why! the idea of making a queen-cage out of wire cloth so exactly the *fac-simile* of a queen-cell, and smearing over the end of it with candy so that even the bees (deluded souls) could not detect it from their own manufacture! Almost any one ought to know better than to make such a statement as that. It is very evident that Mr. Walsh got his information entirely from books, and that his vivid imagination quite ran away with his good sense. As a bee-keeper we have never before heard of him.

#### HOW THE OHIO PURE-FOOD LAWS WORK.

OUR Mr. Weed, who has been selling our honey in Akron, has run across some glucose mixtures put up by a concern notorious for selling adulterated honey and syrups. This same firm evidently sell their mixtures as *pure goods* in States where the laws are lax or are not very rigidly enforced. In a State like Ohio, for instance, where we have a good pure-food law, and a food commissioner who sees that said law is enforced, they put out the same goods, but on the back of the package they put the formula of the so-called honey, in fine print, which they are obliged to do to conform to our Ohio law. Their expectation is, of course, that the consumer will not stop to read the fine print, but take it as pure goods.

Well, it seems this concern, through its representative, sold a consignment of the stuff in jelly-tumblers to a firm in a town near Akron. They represented, at the time of making the sale, that the goods were pure; but on their arrival, or at least soon after, it was discovered that there was a small label on the back of the tumbler, containing the formula of glucose, honey, and sugar. But the goods had been paid for, and the grocer had the stuff on his hands. It would not sell, and he had no heart to push it either.

We expect to give the name of this glucoser, and all the facts in the case to the U. S. B. K. U. Personally, I believe it is a good case; and if the Union does nothing more than to expose the name of the firm, after securing the proper evidence in the form of affidavits, it will have done a good work.

From the foregoing it will be noted that the practical effect of our Ohio pure-food laws

is to do away with glucose competition in honey. Other States have good pure-food laws; but they lack good food commissioners to enforce them. Now, what can be done in Ohio can be done in other States; and I am not sure but that this would be another very good field for the U. S. B. K. U. to work in; namely, to punch up commissioners who are negligent of their duties; and, failing to enforce the laws, to secure the appointment of other men in their places. We need men with backbone to enforce pure-food laws, just as we want them in every responsible position.

#### CASTING BREAD UPON THE WATERS; HOW TO WHET THE APPETITE OF CONSUMERS FOR HONEY.

IN order to disseminate information in regard to honey as a food, and to create a taste for it, we have been inclosing our honey-leaflet in every one of the envelopes that go out of our office. One such leaflet found its way to H. W. Richardson, Section Director of the Weather Bureau of the U. S. Dept. of Agriculture, whose office is located at Columbus, O. In a letter dated Nov. 19 he writes:

I thought your little circular on honey so interesting that I gave a copy to a reporter, requesting him to give you credit for extracts made from circular, which I see he did not do, as perhaps the newspaper regarded the same as an advertisement. Anyhow, the publication won't hurt the A. I. Root Co., as several parties have applied to me for copies of "bulletin," and I have referred them to you. If you could send me a dozen of these circulars I should appreciate it.

The result was, the reporter gave it a handsome write-up, making liberal extracts, the same appearing in the *Columbus Dispatch* of Nov. 18. This started a good many inquiries in regard to this leaflet that was styled, by the reporter, "A Bulletin issued from the Weather Station." I suppose Uncle Sam, in the reporter's estimation, gave it a sort of "tone," and that is why he gave it such a liberal notice. Well, it has done a good deal of good already.

This point struck me right here: Suppose bee-keepers were to hand a copy of this honey-leaflet to the editors of their local papers, and ask them to give it a write-up or to make extracts from it. Who knows but it would do a great deal in the way of whetting up the appetite of consumers for honey? The Section Director of the Weather Bureau at Columbus regrets that the reporter entirely ignored the name of The A. I. Root Co. We do not care a fig about that. All we care for is that, somehow or in some manner, consumers shall know about the value of honey as a food. Credit? Why, we do not want any; and I am rather of the opinion that, if our name had been used in connection with such a write-up, people would have turned away, thinking it was a neatly gotten-up advertisement. Let all names be omitted, but let the *facts* go traveling around the world. Visit your reporters and local editors. We will furnish copies free for such purposes.

Another thought comes in right here: If every bee-keeper would mail a copy of the honey-leaflet in letters that he writes it would help greatly to scatter the right kind of seed.

It is by casting our bread upon the waters that we reap.

**M. G. CHASE, THE GILT-EDGED-HONEY MAN.**

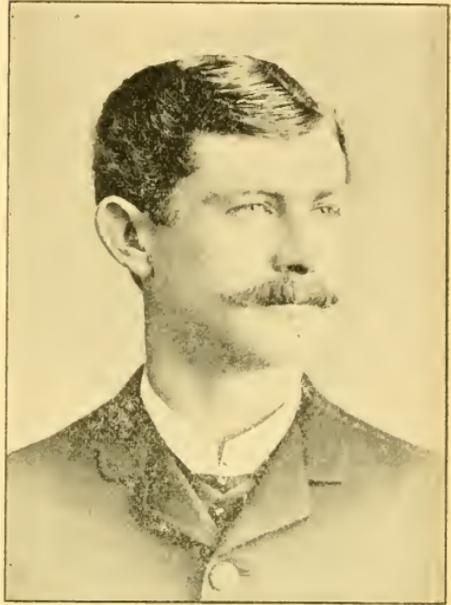

SOME little time ago I gave a picture of Vernon Burt as one of the bee-keepers in the immediate vicinity of Medina whom it is my privilege and pleasure to consult occasionally on the various subjects that pertain to our pursuit. Mr. M. G. Chase, whose postoffice address is Whittlesey, some eight or nine miles southwest of here, is another local bee-keeper with whom it is my privilege to talk bees. Whenever a new thing is brought out at the Home of the Honey-bees the opinion of both of these men is sought, and the following season they are given samples of the new things to test. During the past season, for instance, both tried for us the deep-cell foundation, and during years past they have tested for us in a similar way comb-honey supers, and various styles of self-spacing frames.

While Mr. Burt makes bee-keeping a specialty, running two apiaries, Mr. Chase manages a 200-acre farm, besides an apiary that varies anywhere from 75 to 125 colonies. He is not only a first-class progressive farmer, but an excellent bee-keeper. If there is any man in this county or in the State of Ohio—yes, and I might say in the whole United States—who produces a really gilt-edged article of comb honey, it is M. G. Chase; and he is likewise one of the first to get his honey on the market.

He took his start in bee-keeping from his father, who had 100 colonies in box hives; but the younger Chase could not keep them that way, and accordingly transferred them, increasing them to 125 the first year; and, if I remember correctly, he secured 22 cents a pound for his honey. This was away along in the early 70's. But his good fortune was quickly followed by disaster in wintering. Just how many he lost I do not know; but he quickly recovered, and ever since has been making the apiary turn out some extra nice honey. His largest yield I think, was 2700 lbs. from 20 colonies, while his smallest yield was about 800 lbs. from 80 colonies. Of late years he has not had the seasons that he formerly had. Basswoods have been cut off around him, and the clovers have disappeared; but somehow even in the poorest seasons he manages to bring up some honey when nearly everybody complains of not getting any, unless it is our friend Vernon Burt and Mr. Chase's brother-in-law, Mr. U. Prince.

And that reminds me that Mr. Prince is another of my consulting bee-keepers. The other day, when he called at our office I showed him the fence and plain sections. He would like to use them next season, but he had so many old fixtures that he could not afford to throw them away; but he was interested enough to try a few when I told him he could use his old supers. Well, this Mr. Prince runs two apiaries, or did the last I knew. The out-yard is managed on the Elwood plan to prevent swarming; namely, the queens are caged in the hives at the approach of the swarming season, and in eight

or nine days the cells are cut out, and again in eight days more. Mr. Prince says it is a great deal of work, but that, by that plan, he can handle swarms when it is convenient for

M. G. CHASE.

him to go to the yard. Mr. Prince also secures a nice lot of honey every season.

I take pleasure in introducing both Mr. Chase and Mr. Prince. They, together with

U. PRINCE.

Vernon Burt and Dr. Miller (who is also my near neighbor), act as a sort of balance-wheel on the boys; and I do not deny that we sometimes need one.

And when they had gathered the church together they rehearsed all that God had done with them.—Acts 14: 27.

Last Sunday a new Methodist church was dedicated in our town. It rained the day before, it rained in the morning, and it rained all day, so that the congregations in all the churches were probably sparse, and we thought it quite likely there would not be a very good gathering at the new church, and that they surely would not be able to raise the money to pay for it. It cost \$12,500. The sum of \$9000 had been already subscribed, so that only \$3500 was to be raised. During the day I attended our own church; but in the evening, as they had a sort of union service at the new church, I was present, and was somewhat surprised to learn that the whole of the \$3500, and *more too*, had been subscribed at the forenoon's service, in spite of the rain. The good brother who managed the matter told us that in matters of that sort there were always some subscriptions that, owing to accidents, sickness, or death, would probably not be paid; and he urged that they might raise about \$250 during the evening service, so as to be sure to have enough; and he mentioned, likewise, that there were still some things very much needed in regard to the church, if they had the money.

It was a gray-haired veteran who called for the subscriptions. He had his \$250 in a very short time. I enjoy meeting men of skill. I like to see a skilled mechanic. I like to converse with a finished scholar; and I enjoy above all things watching a man who has the power to manipulate a congregation of people—I mean, of course, where he manipulates them for God's righteousness and God's kingdom. It seems to me a little strange that a people who can not all of themselves and among themselves raise money to pay a debt will do it easily when they get some old hand in among them to stir them up to a sense of their shortcomings. I do not know very much about such things; but I have often heard that they pay a stranger from fifty to a hundred dollars, and even more, to come in among them and tell them what they *know* already they ought to do.

On Tuesday evening we had a sort of union meeting in this same church. The ministers of the five churches of Medina all sat on one platform, and we had five short sermons. Some of our older readers may remember that it was during a union meeting something over twenty years ago that I broke away from indifference and skepticism, and united with God's people; and during the evening I speak of, it kept coming constantly into my mind that my first public testimony was in a union meeting in that same Methodist church—not in the same building, but in the old building that stood on the same ground. One of the ministers was an old white-haired veteran.

He told us about church people and church-going fifty years ago. As he described it so vividly my mind went back to the meetings in the schoolhouse.

He brought many smiles to the faces of the younger ones by telling them how those evening meetings were lighted. The people who were most interested brought each a tallow candle. The candle was first lighted, then tipped over till the tallow dropped on the corner of the desk; then the broad blunt end of the tallow dip was held down in the melted grease until it "froze fast." The candle then stood securely during the whole evening unless somebody bumped it over. Another way was to stick a penknife through a candle and drive the blade into the window-casing. This did very well unless the room became too warm, and somebody wanted a window let down a little. Then the draft would make the candle "flare." Pretty soon the tallow would run down and drop on somebody's Sunday clothes—perhaps on some young man's coat that he had put on in order to take his "best girl" to "meeting." Sometimes the melted liquid dropped on some good lady's Sunday bonnet. The speaker stated that people were then a good deal as they are now; and sometimes, so Elder Cooley told us, there was "more grease on the bonnet than there was Christian grace in the heart" after the accident had happened. He said the minister sometimes used to ride horseback ten or fifteen miles to meet his appointment, and the people would hardly be satisfied, after having taken pains to go so far, unless he gave them a sermon at least two hours long. The people usually came in lumber-wagons, and he said the wagons were almost always full. In fact, they would drive around to the neighbors' homes, and the invitation to go to the meeting was seldom unheeded.

What a change fifty years have brought! A good many of the younger people who read this probably never saw a tallow candle in all their lives. Huber has seen them, for a few nights ago he had one in a Chinese lantern dangling at the tail—no, it was not at the tail, for the *kite* that carried the lantern was a modern "tailless" one. It dodged about and "cavorted" over the town during the dark night for an hour or two; and very likely lots of people will believe, as long as they live, they actually did get a glimpse of the "air-ship." Huber tried lamps, but the old-fashioned sperm candle seemed to answer best.

Well, the candles are gone; and now, in the churches, at least, the lamps are going. This beautiful new church was lighted by electricity. In the very center of the dome overhead a cluster of sparkling globes flashed and glowed like a beautiful flower, each petal of which was like unto a shining meteor; and lesser lights were scattered here and there lower down on the ceiling and along the walls. They were lighted as if by a flash of lightning, and extinguished as quickly. How convenient! how beautiful! how grand! No matter how many times I see these incandescent globes—no matter if I do meet them now at every turn in my *own home*, again and

again have I raised my heart in thanksgiving and praise to God for what electricity is doing to light and cheer our homes. Already electric globes are kept going by the power of the wind that sweeps over our heads, and they are getting to be more and more common. This church was not only lighted by electricity, but it was warmed by steam. The radiators are *ornamental* as well as useful; and by their use the room can be evenly warmed all over so there are no cold spots and almost no spots that are *too* warm. The decoration is new and very pretty. On a large plain plastered wall the figure of a shepherd's crook and of a cross is seen resting in the clouds. I looked at it again and again, and enjoyed it as I did the strains of beautiful music from the trained choir. And this reminds me that the veteran elder who told about the old times spoke about the singing in the old log schoolhouses. He said that, away back in those early days, they had some old hymns that, in his opinion, would never be surpassed. He mentioned especially the one beginning—

A charge to keep I have,  
A God to glorify.

He turned to the choir, and said: "Oh! yes, you can sing it, I know you can; but you can't sing it as they did then."

Some of them smiled because he was so very positive; but he remarked again, "I beg your pardon, but you can't do it, neither can any man or woman living. Those things are gone by."

Although they had some fierce conflicts in the church in those times, they had considerable of the grace of God also. When it first began to be customary to have an organ for worship, one old deacon stood out very stubbornly. He was a man of wealth and influence. Well, the good church people, after exhausting their eloquence and grace in trying to soften him, *prayed* for him, and prayed that God would help them to get an organ. Another meeting was held, and, greatly to their astonishment, the good brother wound up his remarks something in this wise:

"Friends, if you absolutely insist on worshipping God by machinery, let us not have any poor affair brought into our church. We want one of the very best 'machines' made, and I will help pay for it."

We may gather two lessons from this incident. First, prayer avails when nothing else will move the stubborn heart. Second, there is oftentimes a good deal of grace in a man, even when he seems, to outward view, all stubbornness and flint.

Then he spoke of the progress that is being made, not only in electric lighting, steam heating, church decoration, etc., but he said he felt sure we were coming nearer to God than we did sixty years ago. He pointed to the row of ministers belonging to the different denominations, and said in substance: "You could not get five churches to unite fifty years ago as they unite and are united now." And as I heard the five different pastors speak to a congregation made up of people from every denomination—yes, and many of them of *no* denomination—I felt that what he said

was true. There has been an advance in the last twenty years. As each one of these five pastors spoke, if he spoke what he really believed and felt (and I think he did), no one of them thought of saying none would be saved except those belonging to his own creed. The thought came to my mind that was beautifully expressed by our own pastor in a recent sermon. I think he said the words were first spoken by Augustine, one of the Fathers of the Christian Church: "In essentials, unity; in non-essentials, liberty; in all things, charity." At the time of my conversion the sight of united bodies of Christian people was inspiring; and whenever I see a movement in this direction it renews and revives that very feeling and inspiration again. In business matters we are learning charity, and, more than all, we are learning to forget injuries. I am sometimes astonished to see people who have had a fierce lawsuit commence friendly relations as soon as it was over; and I am surprised to see the man who has been wronged and cheated turn around and do a kind act to the neighbor who cheated him; and when business matters have unexpectedly brought men together who have had serious difficulty, I have been gratified again and again to see them do each other a good turn, just as if their former unpleasantness had never happened. Notwithstanding serious troubles lie before us as a nation, I do feel that we are gaining ground spiritually, and sometimes people seem to be catching the spirit of the beatitudes without even knowing or realizing that they are unconsciously showing forth a Christian spirit. I once heard a merchant say, who was very patient, and seemed almost Christianlike, "Oh! we never quarrel with people, especially with customers. *That* would not be 'business.'"

I want to call attention to one point made by the good brother who raised the money. It was something like this: "Now, look here, my good people. You know who have subscribed. You have heard their names mentioned here. You will remember pretty nearly just how much each one has given. Tomorrow morning when you go out on the streets you watch their faces. Every one who has helped in this work will wear a good broad smile. The people who have not given any thing will look sour and cross. Probably they will be cross at the weather and at almost everybody. Can you afford to let such an enterprise go forward in your town, and not lend a helping hand?" As he spoke of the enterprise he waved his hand as if directing attention to the electric lights aloft, the beautiful mottos on the wall, the new, easy, and comfortable seats, steam-radiators, not forgetting the ample ventilation and all the other things. Dear reader, are you wearing a broad and happy smile about your daily tasks? If not, is it not possible you have forgotten or neglected to look after the churches in your vicinity, and to lend a helping hand? Have you been present on such occasions as I have mentioned? and have you been one of those who were "gathered together" as in the language of our text?

## PROMPTNESS AND RELIABILITY IN BUSINESS.

## Their Bearing on the Matter of Work and Wages.

BY A. I. ROOT.

Just now there is not so much being said about competent people being out of work; nor is there so much discussion and contention regarding the wages people shall receive; but I feel once more impressed to take up the subject, and point out at least one reason why so many people do not have a permanent situation, and why the pay is small when they do get a job, and it is in this matter of reliability. We have a notice up almost constantly at the time-desk, which reads something as follows:

"Those who leave their work without giving notice (or getting permission) must not complain if they lose their places without notice."

Notwithstanding this, we are annoyed constantly, year in and year out, by certain persons who will leave their job at any time they feel like it, without saying a word to the foreman or anybody else, and come back the next day, or later, and expect to go to work without any notice or apology for their absence. As an employer of many hands, perhaps I look at this matter from a selfish point of view; but I think there is justice in my position; and, even though there be something to be said on the other side, I feel sure you must all admit that I am at least in some respects right. When you hire a man to do some work for you, it is a contract like all other contracts; and it is one of the first business axioms that any man should either keep his business contract or promise, or get a release from said business contract or promise. When a man is hired regularly at so much a day or hour, he agrees, indirectly if not directly, to be on hand at regular hours; and to be consistent and reliable he should be at his post or else get permission from his employer or foreman to be absent. If he absents himself without saying any thing, or comes an hour or two hours late, he causes trouble and expense in a way one will not readily understand until he has had charge of men, and had charge of work that is important. With the irregular man, the foreman can only keep watching and waiting, thinking he will be along soon. Finally, when it begins to look as if he were not coming, somebody is selected to fill his place. To do this, annoying changes have to be made. Two or three men have to be changed about, frequently, to get one who understands the particular work of the absent man. After these changes are made, and every thing is running fairly well, the absent man turns up. Then they have to go and change back again. Sometimes a new man has been employed temporarily, and this man must either be sent home or kept at a loss. I have known goods to be returned because of defective workmanship; and after an expensive investigation we find the trouble came in right where one man stayed away and somebody else was obliged

to take up his job where he left off. The one who had started his job had careful instruction, and was watched until he did it all right. When the change was made, the one who gave these careful instructions knew nothing about the change, and so did not have an opportunity of making plain to the new man what was wanted.

Perhaps our friends do not all realize that it is only *certain ones* who are missing when they are wanted most. There are those in our employ who are sick every little while, and give that as an excuse for going away without notice. There are others who always miss a train by accident. I suppose it never occurs to them that it looks singular that *they* should always be having such accidents when others around them do not.

Last Saturday (Nov. 6) was a beautiful sunshiny day, after having had almost a week of rain. Two men were set unloading a car of lumber. They could have finished it easily by night, and their foreman supposed they would do so of course. Late on Saturday afternoon it was discovered that neither one of them had been at work since noon. As all the other hands were busy, the lumber was left, just as they dropped it (when the whistle blew at noon), all day Sunday. On Sunday it rained. Now, neither of these men asked permission to be away, nor did they inform their foreman that they would have to be away. They simply dropped their work, leaving the lumber all scattered about so it was not in condition to be protected from the rain, without saying a word to anybody. One of these men had persisted in doing this thing so repeatedly we had tried to get rid of him; but because of a poor overworked and sickly wife we had taken him back several times, with his promise to give notice, hereafter, when he was to be away.\* The other man was one whose wages had been recently advanced, and was a sort of second foreman, so he could, during the noon time, have easily arranged with somebody else to finish unloading the car.

One man once gave as a reason for not speaking to his foreman, that, whenever he had asked to be away, the foreman was almost sure to refuse to let him go, and that was his reason for going away *without* notice. This man was running a machine. If his machine should stop, several others would be thrown out. When I spoke to the foreman about it he said he could usually make arrangements to let a man go when necessary. Sometimes, when there is to be a car loaded, and the force is kept up late at night to do it, it is very inconvenient to have a machine stopped. A great part of the year, however, we have a surplus of help, and a great many times it is really a convenience to us to have a man ask to be away. In the fall of the year we often give vacations for two weeks or more. If the man who wants to be away will talk over the matter with his foreman or employer, very

\* I have since learned that this man left his work to attend a sale in the neighborhood. Which is of more importance—attending to your legitimate business and holding your job, or going to a sale without leave of absence?

often arrangements can be made to their mutual advantage to have him away.

Now, there is another point I wish to touch on where you may think I am selfish, and looking on only one side of the matter. There are two ways of getting away from a job. One is to tell the boss that you have *got* to be away for the afternoon, and then go off and leave him before he has had a chance to explain to you the situation of the work. Another is to say, "Mr. A. I should like to get off this afternoon, if you can manage to get along without me." This latter way is getting permission, while the other way is simply giving notice that you are *not* going to work. Some people think it is stooping to ask *permission* of an employer to be away. Now, I will tell you how I look at this. If the President of the United States should contract for some work,\* and then something should turn up that he did not want it, I should expect him to get *permission* of me to cancel his order; and that is the custom in all other business transactions, except that of employing labor. When a man wants to be released from a contract he *asks* to be released.

On my wheelrids I have frequently called on bee-keepers. They are almost always reliable men, and men of property; yet when they change their plans of work to give me a day or half a day it has pleased me to see them go around and get permission to put off work they had planned. When I visited Mr. Hugh Vankirk, and he wanted to go with me over to the oil-wells he put a lot of tools into his buggy. Then he drove out of his way to where he was to do a job of mason work out in the country; and he asked for permission to put off building that chimney, or something of that sort, until the next day, explaining the circumstances. Now, I suppose the good housewife had got her carpets all up, and every thing arranged for the new chimney; but in a pleasant and neighborly way she said, "Oh, yes! go ahead; we can get along one day more, any way." She may not have used those very words, but it was something like it. Suppose he had started off and left them and the house all torn up, just because it was a little trouble, and made our drive a longer one, to go around and get a release. Do you see the point? What is for your employer's interest is for *your* interest. Almost everybody nowadays can, if he tries, not only secure a permanent job, but most of us can look forward to an advance in wages; but, my dear friend, you can not hope for any advance when you annoy and perplex your employer in the way I have indicated. Why, high-priced men in every calling expect to give notice when sickness or accident prevents them from being at their accustomed places. Our engineer once sent his wife up before daylight, in the winter time, to let us know that he could not be on hand to fire up. It really

seemed to me almost too bad when I saw the woman coming so early, but it was really the only thing he could do consistently.

One thing more right here before closing: I have been greatly annoyed because the boys who have been with me all through the forenoon would leave word with somebody else, without saying they wanted to be away, and then "somebody else" would forget to say any thing about it. Sometimes I say, "John, why didn't you tell *me*, instead of telling somebody else? I was right with you just before dinner." John hangs his head, and does not say a word. Sometimes I hear that a certain man had told his companions that, if he did not "feel better" after dinner, he did not think he would work. Now, when his boss or employer passed him several times during the day, he did not say any thing to him about it. He simply mentioned it to somebody who was working with him, and I do not often find out about this until I have spent considerable time in asking if *anybody* knew why this man was not in his place. Do you say it is too much bother or trouble? Then, my friends, you must work for lower wages, perhaps all your life, or you must be out of a job every little while. When we are discussing as to which ones to keep through the winter, the man who is not to be depended on gets left out. Even if he may have unusual skill, if he annoys his employer in the way I have mentioned his skill counts for little or nothing. I have known of a man who had the key to the warehouse in his pocket to stay away without notice, and when we would send a boy after him he could not be found, and we had to break the lock and put on a new one.

If, owing to ill health or some other circumstance, you want a place where you can go and come without notice or warning—why, make a bargain that way, and have it understood, and work for low wages accordingly.

Now, if in this little talk I have helped any man, woman, or child to get a permanent situation or better pay, I shall be glad; and I know that every one who hires help will say amen to the position I take. Reliability and promptness help everybody and every thing. If order is heaven's first law, I think that reliability and promptness must have been the next one.

---

## THE SCIENTIFIC APPLICATIONS OF ELECTRICITY TO THE INDUSTRIES OF THE DAY.

The Place it will Probably Take in our Homes.

BY A. I. ROOT.

A few days ago a good friend wrote to me, lamenting that I had no faith in electricity as a curative agent. I hastened to correct his mistake. What I have said in regard to Electropoise, Oxydonor, and Elektrikure, has had no bearing on electricity at all, because there is no electricity about them—never was, and the men who manipulate them and sell them to the suffering sick well know that not a particle of electricity can be detected about

---

\* We have not as yet had an order from the President of the United States; but we did have one from the government at Washington, and the carload of goods went yesterday. If we were not on hand, and up to the times, we certainly should not thus be honored by the head of our nation.

them by the most scientific and delicate instruments. I know real electricity has been used for the cure of diseases. In fact, Ernest has used it quite successfully recently for an acute attack of rheumatism. It banished the pain instantly. I believe, however, it gave only temporary relief, enabling him sometimes to get sleep nights when he might not have done so otherwise. I am sure, however, a great deal of fraud has been practiced, even with genuine instruments, in applying medical electricity. No intelligent physician of the present day claims that electricity of itself *cures* disease. It oftentimes assis:s, however, and gives temporary relief, much in the same way that exercise, friction, or manipulation like massage does.

But for the present I have something else to talk about. Not only have I been watching since boyhood to see electricity used to run cars, but I have been watching anxiously of late years to see a *portable* electric lamp. Like the astronomers of fifty years ago who turned their telescopes where Dr. Gall told them to look, I have been watching for an electric lamp that would give an instantaneous light when you "pressed the button," but which would stop the light and stop the waste of force whenever the button should be released; and I wanted this lamp to be portable. I do not like a lantern, for it is a dangerous thing to have around the barn and stables; and when you want it in a hurry it is not lighted. For years past, when I have wanted to consult the barometer on the porch on a stormy night I have been obliged to light a lantern or carry a lamp (smoking up Mrs. Root's bright clean chimneys), or else light match after match in the endeavor to catch a glimpse of the column of mercury before the match was extinguished by the blast.

Within the last month I have secured such a lamp. It cost only \$2.50. The current is produced by four dry batteries. The manufacturers claim these batteries will run 200 hours; and this time may be made up of flash light, one minute at a time, five minutes, ten minutes, or an hour. You may be a whole year in using up the 200 hours if you choose. When your batteries are exhausted, you can get four new ones for 72 cts.; so you see the cost is only about a third of a cent an hour. Where you use your lamp for flashing a light on the dial of a clock when you wake up in the night, and for such purposes, it would last almost indefinitely. I have used it for riding my wheel, and I can easily keep on the walk, or keep out of bad places in the road, the darkest night you ever saw, by the aid of this little electric lamp. The only objection to it is the small amount of light it gives. I understand there are other ones in the market that give a stronger light, but they run for only about twelve hours—that is, after you have pressed the button a sufficient number of times so it all adds up twelve hours, your batteries will have to be replenished; and with this stronger light the expense may be half a cent an hour or more. Such a lamp can be turned upside down, or any way you choose. You can push it down into a sewer,

or use it for lighting up any place where you can not readily get a lantern. In fact, it will light up an overcoat pocket, a rat-hole, or any other place where you want a strong light to penetrate.

I have before told you that, with the proper appliances, the same wire\* that runs an electric light will also cook food, heat water, apply heat to any part of the body of an invalid, or for a thousand other purposes where heat or any degree of warmth is wanted. This is comparatively well known. Just now I am in receipt of a catalog stating how, by means of an electric wire, cold may be produced or applied in a similar way. Of course, what I mean by producing cold is abstracting heat. This electric wire runs a motor, and the motor causes ammoniacal gas to circulate through pipes large or small as may be desired, so that you can heat one corner of your room and cool off the other by the simple force of an electric current. I made inquiries in regard to the apparatus, with the view of keeping my potato-cellar so the potatoes would not sprout, even in the month of June. I can keep our cellar cold very well until along in March, without any apparatus. After that, with the aid of the cold-machine, during occasional warm spells I can keep the potatoes just right to plant, or for table use. Of course, this has already been done by the use of ice. But ice is expensive, bulky, and is apt to be sloppy. Our potato-cellar is already lighted by turning the button of an electric lamp when we want to go into it. Now, if I can, by turning another button, cool it off when it gets too warm, I shall be quite happy—or at least I think I shall. The electrical refrigerating-apparatus is going to be superior to an ice-chest because you can have it close up to the dining-room and you can have your heat and cold so near each other as to save many steps. When the good wife can, by suitable arrangements, avoid the necessity of keeping a hired girl, it is quite a saving in money, and sometimes a saving in nerves. Don't understand that I am tilting at the average help in the home; but I have been thinking that, if electricity should begin to encroach on the domain of the hired girl, it might have a wholesome effect—we will say on the home, for instance. †

Once more, in a recent number of the *Scientific American* I saw a picture of a dynamo and water-motor combined. The price is only \$8 00. The said dynamo has capacity enough to run a single lamp. I wrote the manufacturers, saying that, whether they knew it or not, they were coming pretty near solving the problem of making the wind or wintry blast, as it passes over our homes, furnish the light for the home circle. On figuring it up, however, I found that, at the present stage of

\*When I use the expression "wire," I mean the usual combination of two wires used for the ordinary electric lamp. The Electropoise and Oxydonor people are the only ones I ever heard of who propose to send *any* thing through a *single* wire.

† Since the above was written I have received prices on the refrigerating-apparatus mentioned. At present the smallest size costs \$300, which, for the time being at least, will keep it out of our potato cellar.

progress in the matter, it will take from seven to eight barrels of water an hour, under 40 lbs. of pressure, to run a ten-candle-power electric lamp. Let me explain. An eight or ten foot windmill would, with a moderate well, pump water enough every day to run a water-motor three or four hours in the evening. This water-motor would carry a lamp that would light up any ordinary room so anybody could read the finest print with ease in the remotest corner. After locating the apparatus it would cost practically nothing. After your lamp has shed its light for about a thousand hours, counting only the hours while it is burning, you would have to get a new one, which would cost you 15 or 20 cts. The water, after it has moved the motor, could be used for watering animals, filling a pond so as to be used afterward for irrigation, or any purpose you choose. The principal expense of this home electric light would be a tub or tank to hold the water in an elevated position. If you have a windmill on a hill higher up than your dwelling, you could very easily get the water-pressure; and your tank would have to be large enough to hold, say, something like 100 barrels, so as to have your lights run all the same if the wind should not blow for two or three days. Storing so much water is rather expensive, I know; but at the present stage of science a storage battery would be still more expensive. Where you have a running spring up on a side hill several feet higher than your home, an electric light could be put in at no expense except the \$8.00 motor and dynamo, and piping enough to bring the water down to the motor. Natural water-powers will very soon be all or very nearly all utilized in the production of electricity; and now I am waiting and watching to see the power of the wind, that is everywhere over and about us all, utilized in a similar way. It may not come in my time, but thousands who read these pages will surely see it—at least that is the opinion of your friend and well-wisher, Uncle Amos.

tances. Of course, we had plenty of rain last spring; and to keep off the sun our experiment station shaded the plants with green bushes. By the time the green leaves on the bushes were dried up the strawberries could hold their own. In this way the strawberries can take the place of early peas, early potatoes, and other early vegetables. The bulletin says, in regard to the use of water:

Instances are on record where the increase in the strawberry crop has repaid the entire cost of the pipes, labor, and water, in a single season, the water being furnished by the city water works.

But further on we read in regard to irrigation:

It has been found that the loss of moisture from unplowed ground may be in excess of that from cultivated soil to an amount equal to an inch and three-fourths of rainfall in one week. A man with a team and sprinkling-cart could not replace the water on an acre of land as fast as it escapes by evaporation from the soil, when it goes off at that rate, if he had to haul the water one-fourth of a mile.

In regard to the importance of stirring the soil after every light shower, see the following:

The importance of stirring the soil soon after a shower is generally known; but in practice, cultivation after slight showers is often neglected. This is because the soil does not become compacted, and no crust forms after slight showers, hence the necessity of stirring the soil at once is not apparent.

And again:

As the two are commonly used, a cultivator is a better machine for irrigating than a sprinkling-cart.

In regard to fertilizers we read:

Experiments here with chemicals on strawberries have, thus far, been negative.

Their report on varieties agrees very nearly with my own. Brandywine is given a very high place. They say in regard to it:

The bulk of the crop ripens very late. It excels the Gandy in productiveness and color.

They also indorse my high recommendation of Carrie, and say as I have said:

Every fruit-grower will appreciate an improved Haverland

In regard to the Lovett, we read:

One would hardly be justified in discarding the Lovett, where a reliable pollen-bearing variety is wanted.

And I was also glad to see them giving the Margaret the high recommendation I expected them to accord it. They say:

Under high cultivation the Margaret has given surprising results. For fancy berries it is unsurpassed.

They object to the Marshall unless it is for home market, because it is rather soft. The Wm. Belt also receives many favorable words. They close with the following:

It is too good a variety to be hastily discarded. It is particularly valuable for the home garden or near market.

The most promising new varieties they sum up as follows:

Aroma, Anna Kennedy, Beauty, Copernicus, Clyde, Carrie, Enormous, Glen Mary, Hall's Favorite; unnamed seedling from A. Luther; unnamed seedling from H. Orewiler; Portage, Ruby, Rio, Staples; unnamed seedling No. 1 from S. H. & A. J. See; Tennessee Prolific.

And here is a list that can *not* be recommended, in the opinion of the experiment station:

Bouncer, Columbian, Equinox, Eleanor, Epping, Gardner, Holland, Mary, Princeton Chief, Satisfaction, Sunrise, Timbrel, Weston.

#### STRAWBERRIES.

The bulletin on strawberries, for September, from the Ohio Experiment Station, is one of the most valuable—at least to me—that has ever been sent out. Considerable is told us about summer planting. During the past season, plants set out very early in the spring were sending out runners in June; and in July very nice plants were rooted sufficiently to take up. These were planted out (at the station) in August, six inches apart, because such an early growth meant more plants than ought to stand on so limited an area. The new bed with plants six inches apart, set out in July or the fore part of August, would make a matted row with plants at exact dis-

The old standard varieties that have gotten a permanent place with almost all strawberry-growers in the land, and that can be recommended for general cultivation, are the six following:

Bubach, Brandywine, Greenville, Haverland, Lovett, Warfield.

I felt somewhat gratified to know that at least four of the above six have been in our condensed list of varieties for years past. Ohio people can get a copy of this bulletin, No. 82, by writing to the Experiment Station, Wooster, O. Those who live outside of this State can find out by inquiry on what terms this very valuable bulletin will be forwarded.

## Humbugs and Swindles.

"REPORT ON A RECENTLY PATENTED PROCESS OF BUTTER-MAKING."

The above heading is the title of a circular from the Department of Agriculture at Washington. There have been so many frauds and swindles sold to ignorant and usually poor people, for a process of making a greater amount of butter than is usually made from the same amount of milk, the Department has issued a circular warning the people against it. The closing words of this circular ought to be sufficient to warn at least everybody who sees this from investing in similar frauds and swindles:

The fact that more or less milk can be incorporated in butter, without the addition of any compound, has been known for several years, and was stated in Farmers' Bulletin No. 12, *Nostrums for Increasing the Yield of Butter*, which was issued from this Department in 1893.

From the above extract you will see that this thing has been running, and people have been swindled all over our land, since 1893. It is a burning shame that the thing should still go on.

### CIGARETTES.

I clip the following from a newspaper:

A fire started by a lighted cigarette destroyed a large building in St. Louis, causing a loss of about \$1,000,000.

Now, please do not imagine that I lay the blame of this especially to the cigarette business. The moral that it points out, it seems to me, is something like this: There ought to be some closer restrictions in regard to this matter of going about with a pipe, cigar, or cigarette, or any thing else that contains fire, in such a careless way as this.

### CONVENTION NOTICE.

The Ontario Bee-keepers' Association will hold their annual meeting in the city of Hamilton, on the 7th, 8th, and 9th of December next. A cordial invitation is extended to all those interested in bee culture to attend. W. COUSE, Sec'y.  
Streetsville, Ont., Can., Nov. 17.

The Minnesota Bee-keepers' Association will hold its annual meeting in Minneapolis, at the new courthouse, on Wednesday and Thursday, Dec. 8 and 9. The Horticultural Society convenes on the 7th, and continues for four days. DR. E. R. JAMES, Sec'y.  
Crystal, Minn., Nov. 13.

**PATENTS PROCURED PROMPTLY**  
AT REASONABLE RATES

## BURPEE'S SEEDS GROW!

Write a postal card to-day for

Burpee's Farm Annual for 1898.

Brighter and better than ever before.

W. ATLEE BURPEE & CO., Philadelphia.

In writing advertisers, mention GLEANINGS.

**The A. I. Root Co.'s Goods At Their Prices.**  
Including their discounts for goods wanted for use another season. It will pay you to send me list of goods wanted.  
M. H. HUNT,  
Bell Branch, Mich.

**FOR SALE.**—My entire stock of bees and supplies at a bargain. Italian stock. I have a large queen trade and will sell in whole or part. Address at once. THEODORE BENDER, Canton, O.

## Prosperity.

It is here and still coming. So are the carloads of bee-keepers' supplies coming from The A. I. Root Co.'s to my distributing points, thus enabling me to sell at their wholesale and retail prices. I keep the best of every thing you need. Send for my illustrated 36-page catalog FREE.

GEO. E. HILTON,  
FREMONT, MICHIGAN.

## Two Bee Papers for the Price of One.

To all new subscribers, and also to those who renew before their subscriptions expire, and inclose \$1.00, we will send the *Busy Bee*, a monthly bee-paper, in addition, free.

THE A. I. ROOT CO., Medina, O.

## Wants and Exchange Department.

**WANTED.**—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules.

ANTHONY OPP, Helena, Ark.

**WANTED.**—One saw-mill, feed and shingle mill.  
W. S. AMMON, Reading, Pa.

**WHAT** will you offer for one b-flat cornet and case, also one e-flat alto, good instruments, practically new? Address Box 321, Clifton, New York.

**WANTED.**—Work, by experienced apiarist, by month, or apary on shares.  
J. B. HENDERSON, Roney's Point, W. Va.

**WANTED.**—To exchange pair of St. Hubert man-trailing blood-hounds, butcher tools, foundation-mill, and bone-mill, for bee-hives in flat or Italian bees.  
ELIAS FOX, Hillsboro, Wis.

It's a pretty book of 68 pages, finely illustrated, worth dollars to every poultryman. A 2c stamp gets it. **GEO. J. NISSLY, SALINE, MICH.**

In writing advertisers mention GLEANINGS.

**500 Young Ferrets** now ready to ship.

Send for price list of ferrets and pure Italian bees, free, to

**N. A. KNAPP, Rochester, Ohio.**

#### BEESWAX.

We will pay 25 cts. cash, or 27 in trade, for average wax delivered here. We expect to need 50 to 60 tons of wax the coming season, and can therefore use all the pure beeswax you can send us. For choice clean bright yellow we usually pay an extra cent or two.

#### ALL GRADES OF COMB HONEY.

We have had a brisk demand for comb honey, and for a time we could hardly get it in fast enough to fill orders. We now have a good supply of all grades at the following prices: Fancy white, 13; A No. 1 white, 12c; No. 2 white, 11; fancy amber, 12; A No. 1 amber, 11; fancy buckwheat, 10; A No. 1 buckwheat, 9. Above prices are for 1 ts of 100 lbs. or more. In 500 lbs. in original crates, as received from producers, 1 ct. per lb. less. The amber grades are especially fine.

#### CLOVER EXTRACTED HONEY WANTED.

With the very abundant crop of clover the past season we ought to be able to get plenty of good clover extracted honey. We are, however, having difficulty in securing enough to supply the demand. We have decided to raise our selling price half a cent a pound, so we shall be able to pay a little more, and may be we can find it easier. Our price will be 7 cts. a pound in 60-lb. cans, 2 in a case. Those who have honey to dispose of will con'er a favor by sending us a small sample, telling how it is put up, and what they ask for it.

#### ANOTHER CAR OF CALIFORNIA HONEY.

We have already sold two carloads of California honey, and are beginning on a third car just received a few days ago. We sold one whole car to one customer. When we were closing out the first car the orders came so thick and fast that it was all gone weeks before we expected, so that we were without any to fill orders with for two or three weeks. We are pleased to say that we can now ship promptly. While the freight on this last car was a little more than on the previous one we propose selling at the same prices: 60 lb. cans, 2 in a case, of water-white, at 6½ cts. per lb.; light amber at 6 cts. In 5-case lots or more, ½ ct. per lb. less. We are developing a large trade among grocers on No. 25 jars filled with California honey, and labeled, shipped 2 doz. in a case, at \$3.50 per case; 6 cases, \$20.00. We can also supply it in square jars, 1-lb., 1 doz. in a case, at \$1.80; ¼-lb., 2 doz. in a case, at \$2.25; 5-oz., 2 doz. in a case, at \$1.70. You have little idea what may be done to increase the consumption of honey till you go to work in a systematic way to educate the general public in various ways to overcome prejudice and create a demand. I do not believe that there is any danger of overproduction of honey if proper measures are taken to increase its consumption.

#### TINKER PERFORATED ZINC.

Among the many makers of bee-keepers' supplies there has been none who turned out nicer or more accurate work than Dr. G. L. Tinker, of New Philadelphia, Ohio. His work was all done by himself, and, consequently, was limited in amount, and high in price. The doctor, for various reasons, has discontinued the manufacture of supplies; and his successors, not having his skill, have not made a success of the business. One of the doctor's achievements was an automatic machine for perforating zinc, the product of which has had the reputation, wherever known, of being the most perfect for bee-keepers' use of any ever made. The machine is a wonderful piece of mechanism. After setting it going on a sheet of any size up to 24 inches, with all the attachments properly set, it will work away, making one hole at a time, automatically reversing itself back and forth over the sheet till the last hole is made, when it throws itself out of gear and waits your leisure to change the sheets and start it going again. In our zinc perforating machine there are seventy punches and dies, and it is practically impossible to have all the holes exactly the same size, while on the Tinker machine every hole is made by the same die and punch, and therefore all the holes must be of the same size. We have come into

possession of the Tinker machine, and expect, for the coming season, to supply this as well as the old-style zinc. The price of the Tinker zinc will be somewhat higher than the old style, as follows:

Tinker zinc strips, ¼ x 18 to 20 inches long, 2 rows of holes, \$1.20 per 100. Tinker zinc sheets, 24x38 or 24x40, 60c per sheet. Tinker zinc honey-boards, 12x19½ to 20, at \$1.50 for 10. For each additional inch in width add 1½c. For each additional inch in length add 1c. For each lot of less than 25 pieces, add 25 cents for setting machine; 25 or over, no extra charge. These prices are about 20 per cent less than what Dr. Tinker charged, and about 50 per cent above the price of the old-style zinc. The Tinker zinc is as near perfection as is possible to make it—no burr edges or variation in size of perforations. We can also furnish the Tinker zinc in drone size—that is, with perforations which will exclude drones but allow the queens to pass.

### Special Notices by A. I. Root.

Blackwalnuts, gathered in the fall of 1896, but in good condition, only 10 cts. a peck.

#### THAT NEW POTATO IN THE GREENHOUSE.

We cut it so as to make 12 eyes. These are planted in pots of jadoo fiber. Of course, they are rather slow in starting, just after the potato was dug from the ground. But about a dozen of the eyes have already made a good start. Some of them are showing green leaves. We expect to grow them all winter in the jadoo fiber, watered with the jadoo liquid.

#### WHO IS DR. SALISBURY?

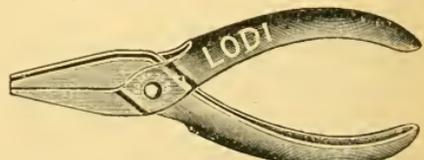

There have been so many inquiries in regard to the lean-meat diet that we have provided ourselves with a little pamphlet headed as above, which we shall be pleased to mail anyone free of charge. It gives a pretty full explanation of the Salisbury treatment; and with the directions given, almost any one can test the matter for himself. I expect it to do real missionary work among those who are suffering from impaired digestion.

#### SEED POTATOES.

Since our last we have sold out of seconds Bliss Triumph and Early Ohio, therefore the only kinds we have now in seconds are Thoroughbred, Freeman, Monroe Seedling, and Sir William. The two latter are \$1.25 per barrel—the others, \$1.50. For regular list of the seed potatoes we have for sale, see page 726 of our issue for Oct. 15. We have still left a few seconds of Bovee and Mamum's Enormous. Bovee seconds are \$1.00 per bushel; Mamum's Enormous seconds, 75 cts. We will still ship potatoes at our risk from danger of freezing, to any point south of Cleveland, Ohio. For points further north we will line the barrels with heavy paper, and do our best to get them through safely; but we should not like to be entirely responsible.

#### SOMETHING NEW IN THE WAY OF PLIERS.

When I was a very small boy I began to use pliers. I wanted them for handling wire, piece of tin, for taking apart clocks, and for repairing other machinery. When I learned the jeweler's trade a pair of pliers was almost constantly in my fingers or in my pocket. I soon learned to value good pliers, and I have carefully watched the improvements in their manufacture. While passing through the store a few minutes ago one of the clerks showed me a pair of pliers costing only 10 cts., that eclipses any thing yet heard of in the line of strength and efficiency, in lightness, and for a very little money. Below is a picture of one of them, but it does not do the beautiful little tool justice.

We have three sizes of them, costing 10, 15, and 20 cts. respectively. They are made of sheet steel stamped out with appropriate machinery, and yet they are

stronger, neater, and hold better than the old-fashioned kind that cost two or three times as much. They are so light that we can send them by mail for only 3, 4, and 5 cts. respectively. The dimensions are, smallest, 4 in. high; medium, 5 inches; largest, 6 inches. If I had been the inventor of this kind of pliers I would swing my hat high in the air and shout "Hurrah!" like a schoolboy.

**VEGETABLE-GREENHOUSES IN DECEMBER; WHAT SHALL WE PLANT IN OUR BEDS?**

Well, judging from past experience we are going to fill our greenhouses mostly with lettuce, as it seems to be most in demand in our market as a winter vegetable. Water-cress may be grown to a limited extent. It is very easy to grow, is not affected by any disease, and will stand quite a little freezing without injury, so if your greenhouse is not very warm it will be just right for water-cress. If you have a market for radishes they will go all right along with lettuce and water-cress. Be sure you have lettuce-plants enough—too many will not do any harm. Where your space is limited, better transplant them at twice. When little plants begin to show the second leaf, plant them out with a spacing-board 2½ or 3 inches apart; the next time, about 7 inches from center to center. If you have a market for green onions they will go nicely with the above. A little parsley, which is also very hardy, will be very nice to mix in with other winter salads. And do not forget spinach. We have for several seasons past sold it at the same price as lettuce, and it is ever so much easier to grow. For seeds of any of the above, see our fall seed-catalog, mailed free on application.

**NOT FOR SALE.** Why do the largest bee-keepers in the world use Bingham Smokers and Uncapping-knives 19 years? Such men know a best thing when they use it. While we have the only exclusively smoker-factory in America, we don't advertise it. It is not for sale. But we do, and have 19 years, made exclusively Bingham smokers and honey-knives. If you get a high-priced Bingham smoker and honey-knife you will have the best as long as you take good care of them. They never go out.

T. F. BINGHAM, Farwell, Mich.

**IF YOU** have good white-clover honey to sell correspond with

120 Broadway, HAYES, BLAIR & CO., Cleveland Ohio.

**BARRED PLY WOUTH ROCKS.** Hawkins' noted strains. A few choice birds for sale cheap, \$1.00 each. FRED H. BURDETT, Clifton, N. Y.

# Gleanings in Bee Culture

## AND American Agriculturist.

Weekly.

**BOTH ONE YEAR ONLY \$1.25.**

By special arrangement with the publishers, we are enabled to offer the American Agriculturist in combination with GLEANINGS IN BEE CULTURE at the unparalleled low rate of \$1.25 for both papers one year. The American Agriculturist is published in five editions. The N. E. Homestead, the Eastern, Middle, and Southern editions of American Agriculturist, and the Orange Judd Farmer. Each contains matter relating to its own locality, as well as the latest and most accurate market reports for the country in general. It has departments relating to all branches of farming, articles written by the most practical and successful farmers, supplemented with illustrations by able artists. Short stories, fashions, fancy work, cooking, young folks' page, etc., combine to make a magazine of as much value as most of the special family papers.

A sample copy will be mailed FREE by addressing AMERICAN AGRICULTURIST, Columbus, O., or New York, N. Y.

TAKEN separately these two papers cost \$2.00, consequently every subscriber under this offer will get

**\$2.00 IN VALUE FOR \$1.25.**

**Premium Books.** For 10 cents extra, as postage, you can have your choice of any of the following standard books FREE: "Profits in Poultry," "Farm Appliances," or "Farmer's Almanac" (ready December 15). Send your subscriptions direct to

THE A. I. ROOT CO., Medina, Ohio.

## Two Papers for the Price of One.

The **Farm Journal**, of Philadelphia, a monthly agricultural journal of 16 pages, sent **One Year Free** for one subscription to **Gleanings**, with \$1.00, paid in advance, either new or renewal. In the case of a renewal, all arrears, if any, must be paid in addition to one year in advance.

The **Farm Journal** is now in its 20th volume, and takes the lead among all the *low-priced* agricultural journals of this country and of the world. It gives no chromos, puffs no swindlers, inserts no humbug advertisements, lets other folks praise it, and makes good to subscribers any loss by advertisers who prove to be swindlers. The editor was born on a farm and reared at the plow-handles, and the contributors are practical men and women.

The regular price of this excellent journal is 50 cents a year, and it is well worth it; but by special contract with the **Farm Journal** we are enabled to make the above very liberal offers.

THE A. I. ROOT CO., Medina, Ohio.

## A Bargain!

**Only \$1.50.** We have made arrangements to furnish **THE OHIO FARMER**, of Cleveland, Ohio, and **GLEANINGS IN BEE CULTURE**, both papers, for only \$1.50.

The **Ohio Farmer** is well known as one of the very best, largest, and among the leading agricultural papers of America. A 20-page, 80-column paper EVERY WEEK in the year; employs THE VERY BEST WRITERS that money can procure; a strong, fearless defender of the agricultural interests of this country, and CLEAN in both reading and advertising columns. IT HELPS MAKE THE FARM PAY.

THE A. I. ROOT CO., Medina, Ohio.

## Honey Column.

### CITY MARKETS.

**NEW YORK.**—Comb honey has been selling rather well the last week; fancy goods fairly well cleaned up; No. 1 and fair-grade goods not having a quick sale. We quote our market as follows: Fancy white-clover comb, 11@12; No. 1, white clover, 10@11; amber white clover, 9@10; buckwheat fancy, 8@9; No. 1, 7@8; extracted honey, N. Y. state white clover, 4½@5½; buckwheat, 3¾@4¾; Cal. white, 5@5½; light amber, 4¾@5; Southern, 5@5½ per gal.; beeswax, 20@27. Both Southern honey and beeswax are in den and.

FRANCIS H. LEGGETT & CO.,  
Franklin and Varick Sts., New York.

**MILWAUKEE.**—Since our last report there has been an improved demand for honey; and our sales, especially of extracted, have been good and quite regular from day to day, which shows that it is reaching the mouths of the people. The receipts of honey have been good, and the demand fair. We quote white 1-lb. sections, No. 1, 12@13; No. 2, 10@11. dark, 8@10; extracted white in barrels and kegs, 5½@6; dark, in barrels and kegs, 5@5½; beeswax, 25@27.

A. V. BISHOP & CO.,  
Milwaukee, Wis.

**KANSAS CITY.**—The stock of comb honey in this market is large; market quiet. We quote fancy white comb, 10½@11; No. 1, 10@10½; amber, 9@10; dark, 8@9; extracted white, 5½@6; amber, 4½@5; beeswax, 20@24.

C. C. CLEMONS & CO.,  
Kansas City, Mo.

**MINNEAPOLIS.**—Fancy white-clover comb, 11@12; fancy dark, 9@10. Market fairly well supplied with all grades. Car or two of California stock still on hand. Local and country demand for white extracted good. Best white clover selling from 5¼ to 6¼.

S. H. HALL & CO.,  
Minneapolis, Minn.

**NEW YORK.**—Our market remains quiet. Stocks are plentiful, and with a slow demand. Prices all along the line show a downward tendency. We quote: Fancy white comb, 11@12; fair white, 9@10; buckwheat, 7@7½; extracted California white, 5@5½; Cal. light amber, 4½@4¾; white clover, 5; buckwheat, 4; beeswax, 26@27.

HILDRETH BROS. & SEGELKEN,  
120-122 W. Broadway, New York.

**ST. LOUIS.**—There is no change in prices since our last quotations. Honey is moving rather slow; outside trade very light; sales confined to local trade; beeswax firm, and in demand.

WESTCOTT COMMISSION CO.,  
213 Market St., St. Louis, Mo.

**PHILADELPHIA.**—The demand is not so brisk as two weeks ago, either for comb or extracted. Beeswax very scarce, and in heavy demand. We quote fancy comb, 13½; No. 1, 12; amber, 10; buckwheat, 8; extracted white, 6; amber, 5; buckwheat, 4. We are producers of honey; do not handle on commission.

WM. A. SELSER,  
10 Vine St., Philadelphia, Pa.

**COLUMBUS.**—While nearby farmers who have small apiaries continue to bring in their honey it has but little effect on the local trade, and a steady demand exists. We are selling fancy white at 13; No. 1, 11@12. We are in the market to buy, and if you have honey to sell send a sample and be sure to name price.

THE COLUMBUS COMMISSION & STORAGE CO.,  
409-413 N. High St., Columbus, O.

**CINCINNATI.**—The demand for comb honey has been good for the last few weeks, and is fair for extracted honey. We quote the latter at 3½@6, and comb honey at 10@13 for best white. There is a fair demand for beeswax at 20@25 for good to choice yellow.

CHAS. F. MUTH & SON,  
Cincinnati, O.

**ALBANY.**—Our market is fairly well supplied with comb honey, and stock selling freely at our quotations. Fancy white, 12@13; fair to good, 10@11; buckwheat, 7@8. The stock of extracted is much smaller than usual at this season of the year, and from advices received we led to believe there is not much in the hands of producers.

CHAS. McCULLOCH & CO.,  
Albany, N. Y.

**CHICAGO.**—There is no change in our market since last quotations were given. Comb honey is slow; extracted, fair movement; beeswax is selling well, and price firm.

R. A. BURNETT & CO.,  
163 South Water St., Chicago, Ill.

**CLEVELAND.**—Fancy white, 12@13; No. 1 white, 11@12; fancy amber, 9@10; No. 1 amber, 8@9; fancy dark, 7@8; white extracted, 6½; amber, 5½@6; beeswax, 28.

A. B. WILLIAMS & CO.,  
80-82 Broadway, Cleveland, Ohio.

**DETROIT.**—Best white comb honey, 11@12; other grades, 8@10; extracted white, 5@6; other grades, 4@5. Demand fair, and supply good. Beeswax, 25@28.

M. H. HUNT, Bell Branch, Mich.

**SPRINGFIELD.**—Good demand. Fancy white clover, 12c; buckwheat, 10c. We should like to correspond with any one having fancy white clover in short-weight packages.

PERKINS & HATCH,  
Springfield, Mass.

**BUFFALO.**—The market price of honey is about as last quoted. Demand is very slow. I think most of the dealers would sell at even a cent off if they could effect larger sales by doing so.

W. C. TOWNSEND,  
Buffalo, N. Y.

**FOR SALE.**—Goldenrod honey, extracted, in cans and barrels, cheap as the cheapest.

J. B. MURRAY, Ada, Ohio.

**FOR SALE.**—Tons of honey, comb, at 7 to 12c per lb. Inclose stamps for samples of extracted at 4 to 6c, in 160-lb. kegs, f. o. b.

N. L. STEVENS, Venice, N. Y.

**FOR SALE.**—Pure honey.—Clover, extracted, 6½ cts per lb.

I. J. STRINGHAM, 105 Park Place, N. Y. City

**WANTED.**—Several hundred pounds first-class white-clover extracted honey in tin cans, crated, for which I will pay 5c per pound. Send sample.

E. P. ALDRIDGE, Franklin Square, Ohio.

**FOR SALE.**—Cheap, 25 bbls of honey.

CHAS. DADANT & SON, Hamilton, Ill.

**WANTED.**—To buy quantity lots of fancy comb and gilt-edged extracted honey.

B. WALKER,  
Evart, Mich., or 211½ E. Chicago Ave., Chicago.

## Wants and Exchange Department.

**WANTED.**—To exchange 140 colonies of bees, with all fixtures belonging to a first-class apiary, for good horses and mules.

ANTHONY OPP, Helena, Ark.

**WANTED.**—One saw-mill, feed and shingle mill.

W. S. AMMON, Reading, Pa.

**WHAT** will you offer for one b-flat cornet and case, also one e-flat alto, good instruments, practically new? Address

Box 321, Clifton, New York.

**WANTED.**—To exchange pair of St. Hubert man-trailing blood-hounds, butcher tools, foundation-mill, and bone-mill, for bee-hives in flat or Italian bees.

ELIAS FOX, Hillsboro, Wis.

**WANTED.**—To exchange a magic lantern, practically new, cost \$15; 80 choice views, cost \$40, for extracted honey, shipping-cases, sections, extractor, or incubator.

E. E. SLINGERLAND, Troy, Pa.

**WANTED.**—To exchange pure White Wyandotte cockerels, April hatched. One for same breed; two for W. P. Rocks.

E. J. BAIRD, Lock Haven, Pa.

**WANTED.**—To exchange one Gearhart high-speed knitting-machine for camera or breech-loading shotgun.

ARTHUR DARST, Alberta, Ohio.

**WANTED.**—To buy potatoes in car lots. Who has them?

F. W. DEAN, New Milford, Pa.

**WANTED.**—To exchange an entire plant of machinery for making V-groove sections and bee-hives; veneer machine for berry-boxes, and 10 H. P. engine. All machines are in good condition. What have you to exchange?

J. B. MURRAY, Ada, O.

**WANTED.**—To exchange 1 roller organ, 12 metallic rolls (used but little), 1 fox hood (2 years old), for miners' magnetic compass, dip-needle, or offers.

N. A. BLAKE, Beebe Plain, Vt.

## Books for Bee-keepers and Others.

Any of these books on which postage is not given will be forwarded by mail, postpaid on receipt of price.

In buying books, as every thing else, we are liable to disappointment if we make a purchase without seeing the article. Admitting that the book-seller could read all the books he offers, as he has them for sale, it were hardly to be expected he would be the one to mention all the faults, as well as good things about a book. We very much desire that those who favor us with their patronage shall not be disappointed and therefore we are going to try to prevent it by mentioning all the faults, so far as we can, that the purchaser may know what he is getting. In the following list, books that we approve we have marked with a \*; those we especially approve, \*\*; those that are not up to times, †; books that contain but little matter for the price, large type, and much space between the lines, †; foreign, ‡. The bee-books are all good.

As many of the bee-books are sent with other goods by freight or express, incurring no postage, we give prices separately. You will notice that you can judge of the size of the books very well by the amount required for postage on each.

### BIBLES, HYMN-BOOKS, AND OTHER GOOD BOOKS.

| Postage. | [Price without postage.]                 |
|----------|--|
| 8        | Bible, good print, neatly bound..... 20  |
| 10       | Bunyan's Pilgrim's Progress**..... 50    |
| 20       | Illustrated Pilgrim's Progress**..... 75 |

This is a large book of 425 pages, and 175 illustrations, and would usually be called a \$2.00 book. A splendid book to present to children. Sold in gilt edge for 25 cents more.

6 | First Steps for Little Feet ..... 50  
By the author of the Story of the Bible. A better book for young children can not be found in the whole round of literature, and at the same time there can hardly be found a more attractive book. Beautifully bound and fully illustrated.

3 | John Ploughman's Talks and Pictures, by Rev. C. H. Spurgeon\*..... 10

|    |   |
|----|---|
| 1  | Gospel Hymns, consolidated, Nos. 1, 2, 3, and 4, words only; cloth, 10c; paper..... 5 |
| 2  | Same, board covers..... 20  |
| 5  | Same, words and music, small type, board cov..... 45                                  |
| 10 | Same, words and music, board covers..... 75   |
| 3  | New Testament in pretty flexible covers..... 05                                       |
| 5  | New Testament, new version, paper covers..... 10                                      |
| 5  | Robinson Crusoe, paper cover..... 10  |
| 4  | Stepping Heavenward**..... 18   |
| 15 | Story of the Bible**..... 1 00  |

A large book of 700 pages, and 274 illustrations. Will be read by almost every child.

5 | "The Life of Trust," by Geo. Muller\*\*..... 1 25  
Tobacco Manual\*\*..... 45  
This is a nice book that will be sure to be read, if left around where the boys get hold of it, and any boy who reads it will be pretty safe from the tobacco habit.

### BOOKS ESPECIALLY FOR BEE-KEEPERS.

|    |   |
|----|---|
| 15 | A B C of Bee Culture, cloth..... 1 10                                       |

| 3  | Amateur Bee-keeper, by J. W. Rouse..... 22                                  |
| 14 | Bees and Bee-keeping, by Frank Cheshire, England, Vol. I, ‡..... 2 36       |
| 21 | Same, Vol. II, ‡..... 2 79  |
| 2  | Same, Vols. I and II, postpaid..... 5 25                                    |
| 10 | Bees and Honey, by T. G. Newman..... 90                                     |
| 10 | Cook's New Manual, cloth..... 1 15  |
| 5  | Doolittle on Queen-rearing..... 95  |
| 2  | Dzierzon Theory..... 10   |
| 3  | Foul Brood; Its Natural History and Rational Treatment..... 22              |
| 1  | Honey as Food and Medicine..... 05  |
| 15 | Langstroth Revised, by Chas. Dadant & Son..... 1 10                         |
| 15 | Quinby's New Bee-keeping..... 40  |
| 5  | Thirty Years Among the Bees, by H. Alley..... 50                            |
| 5  | Bee-keeping for Profit, by Dr. G. L. Tinker..... 25                         |
| 5  | The Honey-bee, by Thos. William Cowan..... 95                               |
| 3  | British Bee-keeper's Guide-book, by Thomas William Cowan, England ‡..... 40 |
| 3  | Merrybanks and His Neighbor, by A. I. Root..... 15                          |
| 4  | Winter Problem in Bee-keeping, by Pierce..... 46                            |

### MISCELLANEOUS HAND-BOOKS.

|   |   |
|---|---|
| 5 | An Egg farm, Stoddard**..... 40                       |
| 5 | A B C of Carp Culture, by Geo. Finley..... 25         |
| 5 | A B C of Strawberry Culture,** by T. B. Terry..... 35 |

Probably the leading book of the world on strawberries.

|   |  |
|---|--|
| 3 | A B C of Potato Culture, Terry**..... 35 |
|---|--|

This is T. B. Terry's first and most masterly work. The book has had an enormous sale, and has been re-

printed in foreign languages. When we are thoroughly conversant with friend Terry's system of raising potatoes, we shall be ready to handle almost any farm crop successfully. It has 48 pages and 22 illustrations.

|   |  |
|---|--|
| 1 | Barn Plans and Out-buildings*..... 1 50    |
| 2 | Canary birds, paper..... 50                |
| 2 | Celery for Profit, by T. Greiner**..... 25 |

The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once without any assistance except from the book.

|    |   |
|----|---|
| 15 | Draining for Profit and Health, Warring..... 1 35 |
| 10 | Fuller's Grape Curstist*..... 1 15                |

This is, perhaps, the most systematic, comprehensive, and thorough work on grape culture now in print; in fact, friend Fuller here tells us how, by easy steps, to make any grapevine come into the work, and make a pleasant orderly appearance; and he makes it as attractive as a piece of fiction; and the best part of it is, that you get great crops of beautiful grapes during almost any kind of season. We have tested the system, and know whereof we speak.

8 | Domestic Economy, by I. H. Mayer, M. D.\*\*..... 30  
This book ought to save at least the money it costs each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life study. The regular price of the book is \$1.00, but by taking a large lot of them we are enabled to make the price only 30 cents.

10 | Farming for Boys\*..... 1 15  
This is one of Joseph Harris' happiest productions, and it seems to me that it ought to make farm-life fascinating to any boy who has any sort of taste for gardening.

7 | Farm, Gardening, and Seed-growing\*\*..... 90  
This is by Francis Brill, the veteran seed-grower, and is the only book on gardening that I am aware of that tells how market-gardeners and seed-growers raise and harvest their own seeds. It has 166 pages.

12 | Gardening for Pleasure, Henderson\*..... 1 35  
While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part; and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 404 pages and 203 illustrations.

12 | Gardening for Profit\*\*..... 1 35  
The latest revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts.

8 | Gardening for Young and Old, Harris\*\*..... 1 25  
This is Joseph Harris' best and happiest effort. Although it goes over the same ground occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.

10 | Greenhouse construction, by Prof. Taft\*\*..... 1 15  
This book is of recent publication, and is as full and complete in regard to the building of all glass structures as is the next book in regard to their management. Any one who builds even a small structure or plant-growing under glass will save the value of the book by reading it carefully.

15 | How to Make the Garden Pay\*\*..... 1 35  
By T. Greiner. This gives the most explicit and full directions for gardening under glass of any book in the world. Those who are interested in hot-beds, cold-frames, cold-greenhouses, hot-houses, or glass structures of any kind for the growth of plants, can not afford to be without the book.

|   |  |
|---|--|
| 5 | Garden and Farm Topics, Henderson**..... 60      |
| 5 | Gray's School and Field Book of Botany..... 1 80 |
| 5 | Gregory on Cabbages, paper*..... 20              |
| 5 | Gregory on Squashes, paper*..... 20              |
| 5 | Gregory on Onions, paper*..... 20                |

The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise

squashes or not. It strikes at the very foundation of success in almost any kind of business.

|  |      |
|--|------|
| Handbook for Lumbermen.....                    | 05   |
| 10 Household Conveniences.....                 | 1 40 |
| 2 How to Propagate and Grow Fruit, Green*..... | 15   |
| 10 How to Get Well and Keep Well.....          | 90   |

An exposition of the Salisbury system of curing disease by the "lean-meat diet."

|   |    |
|---|----|
| 2 Injurious Insects, Cook.....                      | 10 |
| 10 Irrigation for the Farm, Garden, and Orchard* 10 |    |

By Stewart. This book, so far as I am informed, is almost the only work on this matter that is attracting so much interest, especially recently. Using water from springs, brooks, or windmills to take the place of rain, during our great drouths, is the great problem before us at the present day. The book has 274 pages and 142 cuts.

7 | Market-gardening and Farm Notes..... 75  
By Burnett Landreth. The Landreths are the pioneer seedsmen of America; and the book is worth fully as much as we might expect it to be. We think we received hints from it worth the price, before it had been in our hands fifteen minutes. It is exceedingly practical, and tells what has been done and what is being done, more than it discourses on theory.

3 | Maple Sugar and the Sugar-bush\*..... 32  
By Prof. A. J. Cook. This was written in the spring of 1887 at my request. As the author has, perhaps, one of the finest sugar-camps in the United States, as well as being an enthusiastic lover of all farm industries, he is better fitted, perhaps, to handle the subject than any other man. The book is written in Prof. Cook's happy style, combining wholesome moral lessons with the latest and best method of managing to get the finest syrup and maple sugar, with the least possible expenditure of cash and labor. Everybody who makes sugar or molasses wants the sugar-book. It has 42 pages and 35 cuts.

4 | Peabody's Webster's Dictionary..... 10  
Over 30,000 words and 250 illustrations.

5 | Manures; How to Make and How to Use  
Them; in paper covers..... 30

6 | The same in cloth covers..... 65  
Covering the whole matter, and discussing every thing to be found on the farm, refuse from factories, mineral fertilizers from mines, etc. It is a complete summing up of the whole matter. It is written by F. W. Semper.

3 | Onions for Profit\*..... 40  
Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with all the enthusiasm and interest that characterizes its author, T. Greiner. Even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

Our Farming, by T. B. Terry\*..... 1 50  
In which he tells "how we have made a run-down farm bring both profit and pleasure."

This is a large book, 6x9 inches, 367 pages, quite fully illustrated. It is Terry's first large book; and while it touches on the topics treated in his smaller handbooks, it is sufficiently different so that no one will complain of repetition, even if he has read all of Terry's little books. I should call it the brightest and most practical book on farming, before the world at the present day. The price is \$2.00 postpaid, but we have made arrangements to furnish it for only \$1.50.

We are so sure it will be worth many times its cost that we are not afraid to offer to take it back, if any one feels he has not got his money's worth after he has read it. If ordered by express or freight with other goods, 10c less.

|  |      |
|--|------|
| 1 Poultry for Pleasure and Profit*.....    | 10   |
| 8 Practical Floriculture, Henderson,*..... | 1 10 |
| 10 Profits in Poultry*.....                | 75   |
| 2 Practical Turkey-raising.....            | 10   |

By Fanny Field. This is a 25-cent hook which we offer for 10 cts.; postage, 2 cts.

2 | Rats: How to Rid Farms and Buildings of them, as well as other Pests of like Character,\*..... 15

|                                       |      |
|---------------------------------------|------|
| 1 Silk and the Silkworm.....          | 10   |
| 10 Small-Fruit Culturist, Fuller..... | 1 10 |
| 10 Success in Market-Gardening*.....  | 90   |

This is by a real, live, enterprising, successful market-gardener who lives in Arlington, a suburb of Boston, Mass. Friend Rawson has been one of the foremost to make irrigation a practical success, and he now irrigates his grounds by means of a windmill and steam-engine whenever a drouth threatens to injure the crops. The book has 208 pages, and is nicely illustrated with 110 engravings.

|                             |      |
|-----------------------------|------|
| 10   Talks on Manures*..... | 1 35 |
|-----------------------------|------|

This book, by Joseph Harris, is, perhaps, the most comprehensive one we have on the subject, and the whole matter is considered by an able writer. It contains 386 pages.

|   |    |
|---|----|
| 7   Ten Acres Enough.....   | 75 |
| 2 The Carpenter's Steel Square and its Uses.....                        | 15 |
| 10 The New Agriculture; or, the Waters Led Captive (a \$1.50 book)..... | 40 |
| 2   Treatise on the Horse and his Diseases.....                         | 10 |
| 5   Tile Drainage, by W. I. Chamberlain.....                            | 35 |

Fully illustrated, containing every thing of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs, to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in doing almost any thing else; and by following the plan directed in the book, one man will often do as much as two men without this knowledge. The book embraces every thing connected with the subject, and was written by the author while he was engaged in the work of digging the ditches and laying the tiles HIMSELF, for he has laid literally miles of tile on his own farm in Hudson, Ohio.

3 | Tomato Culture..... 35  
In three parts. Part first—by J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second—By D. Cummins, of Conneaut, O., treats of tomato culture especially for canning-factories. Part third—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general. This little book is interesting because it is one of the first rural books to come from our friends in the South.

3 | Vegetables under Glass, by H. A. Dreer\*\*..... 20  
This is by a veteran in the work, full of illustrations from real life, and by all odds the most valuable book we have ever had for such a small price.

3 | Winter Care of Horses and Cattle..... 25  
This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in the book. It has 44 pages and 4 cuts.

3 | Wood's Common Objects of the Microscope\*\*.. 47

8 | What to Do and How to be Happy While doing It, by A. I. Root..... 42

THE A. I. ROOT CO., Medina, O.

## KIND WORDS FROM OUR CUSTOMERS.

J. A. Golden's article in Nov. 1st GLEANINGS, entitled "How and why the No-bee-space Sections of Honey bring a Higher Price," is the very best piece yet printed. Circumstances in its case will be a wonderful advantage to the bee-keeping world.  
Kingston, N. Y., Nov. 8. AARON SNYDER.

I have not been interested in bee-keeping for several years, but am still a constant reader of GLEANINGS for the sake of what Uncle Amos has to say about gardening and in the Home Papers. They alone are more than worth the price, and are always looked for and read with interest by every member of our family, though the table is piled with unread papers and magazines.  
C. N. FLANSBURGH.  
Leslie, Mich., Nov. 16.

The 3 barrels of seed potatoes (Thoroughbred, Early Ohio, and White Bliss) came in good shape, and I am much pleased. They are the best early potatoes I know of. I thank you very much for sending me 9 big bushels.

Bees have done well this season; but the price of honey is only 8cts. for the best, and it is very slow sale at that.  
THOMAS OBERLITNER.

Deshler, O., Nov. 1.

There is one thing that especially pleases me in the above. Our good friend calls the "11 pecks, which we put in for a barrel, "nine big bushels." I suppose the explanation is that so many measure up potatoes, and in measuring they seldom get over or as much as 60 lbs. Our potatoes are all weighed in sending them out, and they usually overrun the measure used for measuring potatoes.

# The Review at Reduced Rates.

The **Bee-keepers' Review** is \$1.00 a year, but, for the sake of getting it into new hands, and being able to begin the year with a large list, I will, until Jan. 1st, send free to each *new* subscriber, a copy of "Advanced Bee Culture," a 50-cent book of nearly 100 pages, that gives briefly but clearly the best methods of management from the time the bees are put into the cellar in the fall until they are again ready for winter—32 chapters in all. Those who prefer can have, instead of the book, 12 back numbers of the **Review**, the selection to be mine, but no two numbers alike. All who send \$1.00 now will receive the last four issues of this year free, and the **Review** will be sent until the end of 1898. If not acquainted with the **Review**, send 10 cents for three late but different issues.

W. Z. HUTCHINSON, Flint, Mich.

# \$100

Given as **BOUNTIES** to purchasers of the improved Danz Hives and Sections. See schedule in my bee-book "Facts About Bees." Tells how to produce honey that sells for the most money. Free for 2c in stamps.  
F. Danzenbaker, Box 466, Washington, D. C.

In writing to advertisers mention **GLEANINGS**.

**BARRED PLYMOUTH ROCKS**, Hawkins' noted strains. A few choice birds for sale cheap, \$1.00 each.  
FRED H. BURDETT, Clifton, N. Y.

Philadelphia Office of

**THE A. I. ROOT CO.,**

10 Vine St., Philadelphia, Penn.

Now is the time to order

**Shipping - cases, Winter Cases,  
Chaff Division-boards, etc., etc.**

Order from catalog; prices are same  
as from factory.

**Another  
Great  
Clubbing  
Offer!**

## Two Great Papers at Price of One.

**GLEANINGS IN BEE CULTURE**  
and the **PRAIRIE FARMER** (Chi-  
cago), both papers for only \$1.00.

This offer is good either to new name or renewal, but in case of renewal all back subscription must be paid up in addition to the \$1 for the two papers. The *Prairie Farmer* is one of the leading farm papers, and is clean in both the reading and advertising pages.

Address All Orders to

**THE A. I. ROOT CO., Medina, Ohio.**

## Shipping-cases.

Root's popular Non-drip Shipping-cases at factory prices at **DES MOINES, IOWA**. Immense stock. All orders for cases or other goods shipped by return freight. Address

**JOS. NYSEWANDER, Des Moines, Iowa.**

## Ten "Bee Journals" for Only 10 Cents!

Send 10 cents and get 10 different numbers of the weekly **AMERICAN BEE JOURNAL** for 1897, five of them being the December issues, and contain the **BUFFALO CONVENTION REPORT**. These ten copies will give you a good idea of the value of the *Bee Journal*. You will want it regularly after reading them. Better write at once before the Buffalo Convention Numbers are all gone.

Address

**GEO. W. YORK & CO.,**

## STRAY STRAWS

FROM DR. C. C. MILLER.

"VIRGINIA" might have the additional information, p 849, that two queens could be wintered in one hive with a thin wood partition between them. A strong colony and a nucleus could thus pass the winter in one hive.

HERR ANDREAS ABEND asserts that a virgin queen may be fertilized, even after beginning to lay drone eggs. Three separate queens, prevented from flying by bad weather, were afterward fertilized, although "buckel-brut" was already in the hive.—*Bienen-Vater*.

A DISCUSSION is on across the sea as to whether bees creep into the cells in winter. So good authority as Rauschenfels and Lutzen insist that they occupy only the spaces between the combs, constantly changing position, and bees found in cells are either dead bees or those that have gone there for food or else because disturbed.

IF IT IS TRUE, as some good authorities insist, that in winter bees don't stay in the cells, then it is easy to believe that Gemmill is right, p. 845, that sealed combs are better than empty ones in the cluster. [I know we have used sealed combs—yes, stuck them right down into the cluster—during cold weather, and have secured good results.—ED.]

A REMARKABLE CASE is given by Dr. Gallup, in *Am. Bee Journal*, which he calls "a case where a queen was compelled to leave for want of room." The colony swarmed and left, leaving a pint of bees, sealed brood the size of the hand, the rest of the combs solid honey—no queen-cell or unsealed brood. Has a similar case ever been recorded? [I do not remember any.—ED.]

THE QUESTION is asked in *A. B. J.*, "Is honey more liable to granulate or ferment in leveled-down sections than with foundation?" Of those trying it, two say yes, seven no; one thinks yes and one thinks no. Three would have cells  $\frac{1}{4}$  inch deep; one,  $\frac{3}{8}$ ; three,  $\frac{1}{2}$ , and three full depth. [As there is such a diversity of answers it would appear that there is no practical difference.—ED.]

I JUST BELIEVE it will be a good thing to have the Pettit idea in the super carried out with the fence. Still, with perfectly straight separators it isn't any great trick to take the unfinished sections from the outside rows of half a dozen supers, mass them in a single super, and have the bees make a nice job finishing them. [Yes, we expect to have that idea carried out in all our 1898 supers. The fence makes its application very simple.—ED.]

ONE MAN used queen-excluding zinc in half his apiary, and ran all for extracted honey. He weighed the honey of the two lots separately, and claimed favor for the zinc.—*N. E. France, in A. B. J.* [And yet there are some who are foolish enough to assert—and I must think they do so without experience to back them up—that perforated zinc should never be used in the hive. Such kind of talk is about as foolish as to say that foundation is a curse to the bee-keeping world.—ED.]

HERR GRAVENHORST quotes what has been said by GLEANINGS about bees hanging out, and says that for years he has avoided it by timely removal of sealed brood to prevent over-populousness, and by wedging up the hive and giving the fullest ventilation. [Giving the fullest ventilation, I am sure, is all right; but I should question very much the desirability of reducing the working force at a time when it may be most needed a little later on. It is the big colonies that get the honey—at least around Medina.—ED.]

YOU'LL LAUGH AT ME, perhaps, but one of the things I enjoyed most at Buffalo was hearing Doolittle cry "'Tatoes! 'tatoes!" in imitation of the potato-vender. It wasn't the fun of the story, although that was good; it was the clear musical ring of his voice. [Yes, I to enjoyed the intonation Doolittle gave to 'tatoes; but "you will laugh at me," perhaps, when I tell you I have forgotten both the application and the story. Will friend Doolittle please tell it to the readers of GLEANINGS whenever an opportunity presents?—ED.]

REPLYING to your question p. 838, Mr. Editor, I've a staggering notion that, after a queen stops laying in the fall, and through winter, she sort of abdicates the throne; and while her royalty is laid aside the bees are somewhat indifferent to her; and a strange

queen coming into the hive would be much the same to the bees as a strange worker. But remember that the notion doesn't stand square and solid on its feet. [Why call it a "staggering notion," doctor? You have offered a very plausible explanation, and to my eye it stands squarely on its feet.—ED.]

E. S. ARWINE, p. 846, seems a little uncertain what may be meant by piping. Small wonder. The term is generally applied loosely to any noise a queen makes. Better follow the German idea as used in Vol. I., *American Bee Journal*. There are two distinct sets of notes used by queens, differing in both pitch and rhythm. In piping, a long shrill note is uttered, followed by several others, each shorter than its predecessor. In quaking, the notes are coarser, more hurried, and more nearly of the same length. A queen never pipes in a cell, and never quaks out of a cell. Perhaps the note of a queen that is balled or grabbed by a worker might be called a squeal, being high pitched like piping.

"A COLONY having a laying queen of the current year's rearing can be pretty surely relied upon not to desire to swarm, no matter how strong it may be within any reasonable bounds."—*R. L. Taylor's Buffalo paper*. That is probably true under some circumstances. One year I gave newly reared queens to prevent swarming, and nearly every one swarmed. But I think the rule works all right with Hutchinson. [The exception proves the rule; but I should say, according to my experience, that there may be quite a number of exceptions to this rule. I have almost come to believe that, in the matter of swarming at least, bees are pretty sure, at least at times, to break over all rules.—ED.]

AS NEARLY AS I can find out from others, 50° is the minimum temperature of a cluster of bees—below that, death. With the surrounding temperature at that point, the center of the cluster may be the same. As the surrounding air gets colder, there is more eating, so as to fire up the center sufficiently to keep periphery at 50°. So the colder outside, the warmer in center of cluster; and it may become so warm in the midst of severe winter as to allow brood-rearing, which requires 86° to 95°. [According to this we have the paradox that, the colder the weather the warmer the cluster. But the query arises in my mind, "If this is so, why will not bees winter better during prolonged severe cold weather than during milder winters?" Perhaps the answer is, "Too much food consumption (and it is certainly true in the human family) causes disease."—ED.]

A PLEASANT SIGHT it is to me to see in some of the hives in the cellar, the bees hanging two inches below the bottom-bars. I don't know whether it's because the hive's so full of bees or because the sealed honey comes down so low, but likely the latter. [Yes, it is a very pretty sight. When we wintered in the cellar I used to enjoy looking at the great bunches of healthy bees under the brood-frames; and at the beginning of winter I would say to myself, "How much better in

the cellar than outdoors in a bunch pinched together about the size of a snowball!" but when spring came on, and the cellar bottom was literally covered with bees an inch deep in places, then I thought to myself, "Would they have died had they been outdoors?" We now winter on summer stands exclusively. If our winters were more severe and prolonged, I suspect we should get better results in the cellar. But our outdoor bees have averaged the best in wintering, and hence we prefer that method for Medina.—ED.]

N. GENN is much in love with his plan for ventilating hives—no entrance either in hive or bottom-board. In spring he puts a loose lath under each side and one under back end. When warmer he takes out the back lath, leaving ventilation clear through. When more ventilation is needed, put two thicknesses of lath under each side, leaving back and front all open. Simple and good, but some will want the greater ventilation given by four blocks. [This, and a good many other items like it, going the rounds of the bee-keeping world, all go to show that large entrances will have to come. And, all in all, I believe that they afford the best solution of the problem of better ventilation. As the editor of the *Review* well remarks, a large entrance can easily be contracted, but a small one can not be enlarged. Putting blocks under the four corners of the hive necessitates prying the hive loose from the bottom, and breaking one's back to get the hive up. How much easier to manipulate a stop or slide weighing an ounce or so to contract a large entrance!—ED.]

"WE USUALLY FIGURE on about 10 pounds of honey per Langstroth frame" is the statement on p. 852. I changed my views about weight of combs after some weighing. Please weigh some. I'll not reproach you with being fickle-minded if you change that 10 to something nearer 5. [After the estimate was printed, the thought struck me that I had put it too high, for the cold print afterward made it seem to me too big; so when I came across this Straw I was quite ready to give up. At all events, following your suggestion, with a pair of spring scales I tramped down to the house-apary through the mud, where we have stowed away a lot of sealed combs of sealed honey, which we always keep on hand for colonies short of stores. I weighed some of the heaviest of these, and the scales showed 8½ lbs.; the medium weights about 6; the light ones about 4; so I shall have to acknowledge, doctor, that 5 lbs. would be a correct estimate to place upon combs as they are usually filled in the hive with winter stores. My estimate of 10 lbs. was based on the fact that, years ago, when we were extracting, we had a good many combs that weighed 10 lbs.; but I had forgotten the fact that we then spaced our frames 1½ inches from center to center, instead 1⅓, as we now do. The thought also stuck in my mind that some of our heavy extracting-supers, which I lifted to put bee-escapes under, must weigh (according to my back) nearly a hundred pounds; but they probably did not stand over 75, including the hive-body.—ED.]

Land Sharks; Something of Importance to Those Who Contemplate Going West; Failure of Water Supply in Irrigated Districts.

BY R. C. AIKIN.

The original plan of our trip was to see the Arkansas Valley, with a view of locating there. I could not make up my mind to leave the alfalfa country entirely. Besides, after one has lived a few years in a dry country he has a dread of rain and mud, so I hoped to find in the Arkansas Valley a low enough altitude to suit my wife, and yet remain in the alfalfa country, dry climate, and irrigated lands. The difference in latitude between the Big Thompson Valley at Loveland and the Arkansas Valley makes the winter about four weeks shorter in the latter. The wintering problem is not so much to be feared as we get more south, which thought also led us in that direction. We intended, however, to view the valley to at least near Central Kansas, thence go north to Lincoln to be at the meeting of the North American in October, beginning the 7th. From Lincoln we were to pass east into Southwest Iowa, my old home, then from there south through Missonri and Arkansas to Texas. As we left Loveland Sept. 2d we had but 34 or 35 days to make a drive of 800 miles or over, see the country, talk bees, and other matters, and visit some friends along the route, etc. Counting out Sundays and all other stops we must average about 30 miles a day, else we should miss the convention. We arrived at Lincoln just after noon of the first day of the convention.

I think perhaps a goodly number of the readers of GLEANINGS will be interested in knowing what we found on that trip, hurried as it was. Some are looking westward for locations because the state of their health demands a change. Others are looking only to find a place to obtain big crops and make money. All together I know that many are anxious to know what is in the West for them, and, knowing this, it is my desire to show Colorado as it is; and right here I want to say to all who may read this, that, should you get "boom advertisements" of favored locations in the West, don't you believe the *lies* they tell.

The Arkansas is a large stream. We found considerable water in it at Pueblo, and quite a strip of country down the valley that was watered and making comfortable homes. This river, as do nearly all mountain streams, has a rapid fall. A stream to supply irrigating water at any reasonable cost must have from 10 to 20 or 30 feet fall to the mile, that the water may be gotten out to the lands without the ditches having to be very long.

Reader, just think of any ordinary river that you know of, then think how many ditches or canals it would take to lead *all* its waters out. A ditch five to twenty feet wide here; another a little further down on the other side. Travel along your river for fifty or one hundred miles, and see every few miles ditches that are almost rivers in themselves, and many smaller ones, all leading the waters out, these ditches themselves being divided and subdivided, spreading out the waters until they simply run out, and you have some idea of how the waters of our streams are utilized.

Think of it in another way. Think how the tiny streams from a great spread of country keep gathering into one another, uniting and reuniting until they become rivers. Just reverse the whole order of this, and send the water out into the vast army of little streams and springs, and you have a system of irrigation in operation. Thus it is that the waters of large streams are turned from their courses and spread upon the *dry* earth until the riverbed becomes dry. Before we got out of Colorado we forded the Arkansas (rather, crossed without a bridge) where the channel was nearly half a mile wide, and not one drop of water was visible—nothing but dry sand and gravel. Now, suppose you had been an early settler there, and had made a ditch from the river, and watered your farm. In the course of years many other settlers have passed beyond you, and taken claims, and made ditches until the river brought you no water, making of your farm what it originally was—a desert. Well, just such things did happen, in more or less degree, until our legislatures took hold of the matter, and now it is so that, as long as the stream has in it "*unappropriated water*," one may *appropriate* and take out water; but since the snow supply in the mountains varies, and as it becomes less, the last appropriation is the first to be denied the right to draw until the "*prior*" rights are satisfied.

Last year was one of short water-supply, and we saw ditches that had not had water in them the whole summer—ditches miles and miles long, covering dozens of farms, and costing thousands of dollars. I verily believe that there is enough barren land—barren only for lack of moisture—east of the Rocky Mountains and west of the Missouri, to consume the waters of both the Missouri and Mississippi.

Now, can you realize what it is to come to Colorado to farm? No, you can not. Come and see it, and still you can not fully realize it. Some boom paper will offer "lands under ditch;" and when you buy and go to farm it you find the ditch dry, or nearly so. Colorado has some fine productive farms, some well-watered country, some nice cities and towns, and, above all, a sunny and rather genial climate; but if you are not familiar with conditions and environments, come and see it before you sell out and leave comfortable homes elsewhere. Almost every one knows pretty much what the East is; but very few in the East know what the West is.

The Arkansas Valley is surely very productive where they have the water-supply; but

the river, though a large one, can water but a narrow strip of country through which it passes. We saw fine farms and quite a number of apiaries in the valley. We also saw quite large tracts of alfalfa where there were few or no bees to pasture it. At Rocky Ford was that extensive apiarist Mr. Hagan. We called at his home, but he was down street. We went down street and met him. I have ever since had a suspicion that friend Hagan did not want any more bee keepers spying out that country, so we passed on. I don't know how much honey that vicinity produced, but melons were everywhere. I was told that, up to that time, about September 15, over 400 carloads of melons had been shipped out.

Las Animas seemed to have many bees too, and there we called at the home of Mr. Oliver Foster, but no one was there. Before leaving town we learned that Mr. Foster and family were out of town for a day or two. As we must be at Lincoln on time we could not wait, so passed on.

We traveled that valley, I suppose, for 400 miles or more; and while there are some good honey locations, there are many more places that would not support even a small apiary.

We have talked much about water. We call the Missouri the "Big Muddy," and I think the Arkansas might be called the Little Muddy. I do not know about the North Platte, but I do know that the South Platte and the Arkansas, and some other streams as well, are so muddy and so alkaline that they are not "respectable" to drink from, and sometimes wholly unfit to either drink out of or wash in.

Very much of the country near the mountains, and in many localities all over the arid regions in particular, is full of alkali. Where irrigating is practiced, the water leaches out the alkali and carries it in solution, so that, wherever the water is found again in springs, wells, or swamps, it is unfit for use. In almost all of the irrigated country with which I am acquainted, a very large per cent of both well and running water is alkaline. A large per cent, however, of the streams before they leave the hills are as clear as crystal, and free of alkali. The cities of Fort Collins, Loveland, Berthoud, Longmont, and Boulder, all near the mountains, and drawing their supplies from above irrigation, have good water. Denver is only medium, while down the Arkansas the only good drink we could get was by eating melons. I am thankful we passed through that valley in melon season. Eastern Colorado, off the streams, where "deep wells" are put down to "sheet water," has good water.

To find church privileges, good water, good markets, good honey resources, etc., in combination, is what we failed to do.

(Continued.)

[Permit me to say a word in regard to farms located where the supply of water is likely to be exhausted. We saw quite a few of them in the neighborhood of Phoenix, Arizona; and I do not know of a sadder sight than a farm where some one has tried in vain to make a

home, and, after having expended both time and money, to see every thing go to ruin just because water was all gone before it reached his ranch. Lots of swindles have been perpetrated, so I am told, by the land speculators, along this very line. My friend Elvey, whom I have mentioned, gave me one case by way of illustration. A friend of his got into the toils of these land pirates; but Mr. Elvey got hold of him in the nick of time, and gave him fair warning. He refused to have any thing to do with them, and went back home—quite a distance, by the way. After he reached home he received a letter from these same fellows, telling of some unforeseen train of circumstances where a valuable piece of property was to be sold for a song, and they finally offered to pay his expenses both ways in case he declined to take up with the offer. He went back again, and the sharks succeeded so well in convincing him that his chance was only one in a thousand that he made the deal without consulting his old friend Elvey at all, and then found that he had been swindled out of almost every thing he had in the world. He moved on to the place, however, used what little means he could scrape up to go on and raise crops, and then became bankrupt. The men who had robbed him just laughed when he tried to get them to stand by what was only a verbal agreement. If you want to buy property, talk with the farmers who are working the land, and not with the land speculators.

In regard to the luscious melons grown around Rocky Ford, we were surprised last season to see that some of them had made their way into our Medina groceries. They were snapped up at once at an advanced price because of the world-wide reputation of these same melons. Permit me to add that we have been having quite a little business in the way of making crates for cantaloupes to be shipped to melon-growers, by the carload. You see there are choice and valuable localities for growing crops under irrigation; but you do not, as a rule, find them in the hands of the land speculators.—A. I. R.]

#### TOMPKINS COUNTY BEE-KEEPERS' CONVENTION AT GREENFIELD, N. Y.

My Trip Through Another One of the Great Honey  
Counties of York State; the George Junior  
Republic.

BY ERNEST R. ROOT.

You will remember that I left Groton with Mr. Miles Morton, in a buggy, to attend the convention at Freeville, which I had been invited to attend; and that, on the route, we stopped to take in one of Mr. Morton's portable house-apiaries, and take a snap shot or two, the result of which has already been given on page 807. Leaving the house-apiary we proceeded on our way to Freeville, a small town located at the junction of two railroads. As it is a sort of pleasure-resort, and is so centrally located, it was selected as the place of

meeting of the Tompkins Co. bee-keepers. Arriving there, we found that the bee-keepers had already begun to assemble; after a general hand-shake and an elegant picnic dinner, we were called to order by Pres. Wood. I will not attempt to rehearse the discussions that took place at that time, as they are now too dimly fixed in my mind. I do remember that I was given two or three friendly "shots," which I suppose were designed to wake me up. I was suffering at the time from a horrible cold—a sort of influenza that I had caught on my return from the Seneca Co. bee-keepers' convention some two or three days before. A night ride on the bicycle, and then afterward, wet with sweat, sitting in the delightful breeze of the cool summer air, so refreshing and grateful, gave me what I deserved.

There were present at that convention a number of bee-keepers who had colonies aggregating from 300 to 1000, and who were just full—yes, brimful, running over—with facts and experiences in regard to bees. Both during the convention and after it I made it a point to pump those fellows as much as I could; and some of the things I have already given to the bee-keeping world have come from those same men.

The president, Mr. Wood, after giving me an introduction, told me that I was expected to occupy the rest of the time; and then those bee-keepers, with their colonies running up into the several hundreds, began to "pump" me. I suspect I told them all I knew about bees, and perhaps some things I did *not* know. Taking it all in all, we managed to have an interesting and lively time. Before the adjournment of the convention, I secured, as a matter of course, two views of the bee-keepers.

#### THE MAN WHOSE BEES DID NOTHING BUT SWARM.

At this convention there was a unique and interesting old gentleman named Luther Greenfield. He had a hundred or so colonies within a quarter of a mile, and invited all the bee-keepers present to visit his apiary. About half of us accepted the invitation. Mr. Greenfield acknowledged that he for some reason could not get as much honey as the other fellows who boasted of their big crops. He almost intimated, in his good-natured Yankee nasal twang, that he did not believe that "them 'ere fellers" could get any more honey than he. In the course of a good-natured banter it leaked out that he had anywhere from six to twelve swarms out at one time during the height of the honey-flow. "Why," said he, "I can get swa'ms, plenty of 'em; but somehe'ow I can't git any honey like you fellers claim."

The "boys" rather poked fun at him a little, because he had, within half a mile of his apiary, one field of buckwheat aggregating a *hundred acres* or more, and various other small fields within range of his bees. I think it was Niver who called upon Mr. Greenfield at one time, and found him employed in the apiary, trying to take care of about six or eight swarms in the air. He was bareheaded, bare-

footed, bareheaded, and baldheaded in the bargain, and the "bees stinging just like Jehu." "What in Sam Hill made the bees swarm so," he could not understand.

"Why," said Niver, "your hives are too small, and your acreage of buckwheat is too large. Give them room—give them room."

While the bee-keepers were in the yard I took one or two snap-shots, one of which I reproduce herewith. Mr. Greenfield himself is in the center of the group, with smoker in hand, just proceeding to open one of his hives. Veil? He did not want any thing of the sort. What did he care for a few stings? At the extreme right of the picture, with white straw hat, is Mr. W. L. Coggshall—the man who manages, with two helpers, a thousand colonies in nine different apiaries. The furthest yard, I think, is some forty miles from his home, and the nearest is some three or four. Just in front of Mr. Coggshall, with his hands behind him, with straw hat, is the secretary of the convention, Mr. J. L. Kinney. Just in front of Mr. Kinney's right, with white beard, light suit, is Mr. Miles Morton, who needs no introduction to our readers.

I was introduced to all of the bee-keepers there present; but for the life of me I can not remember another one save the young man at the left of the picture, who has a straw hat in his hand. That is Mr. Coggshall, junior, who helps his father considerably in the management of their extensive apiaries.

#### HARRY HOWE, THE LIGHTNING OPERATOR.

Just back of Luther Greenfield, with his head obscured from view, is Mr. Harry S. Howe, of Ithaca, N. Y., but formerly in the employ of Mr. Coggshall, of West Groton. Mr. Howe is a young man in whom Mr. Coggshall has taken a special interest—in fact, almost brought him up. Harry was bright, active, and earned the title of being one of Coggshall's "lightning operators." "Why," said Mr. C., "that boy could handle more colonies, and extract more honey—in fact, do any other work among the bees in a given time—than any other man or boy I ever knew." Harry has had to work his way through life from a boy up. He worked days and studied evenings, and latterly has for a number of years taught school. It was he who subsequently showed me through the buildings of Cornell University; and while he did not profess to be one of its students or graduates, he seemed to be well up in some of the departments of learning of that institution. But I suppose one reason why I was attracted so strongly to Harry was because of the fact that he is an ardent bicycle man. While I was with him part of one day we talked not only bees, but bicycles and every thing connected with them.

But to return. I took two or three snap shots of Harry as he was riding on his favorite bike—one he made himself; but, unfortunately, it was near the end of the film, and the pictures were "no good."

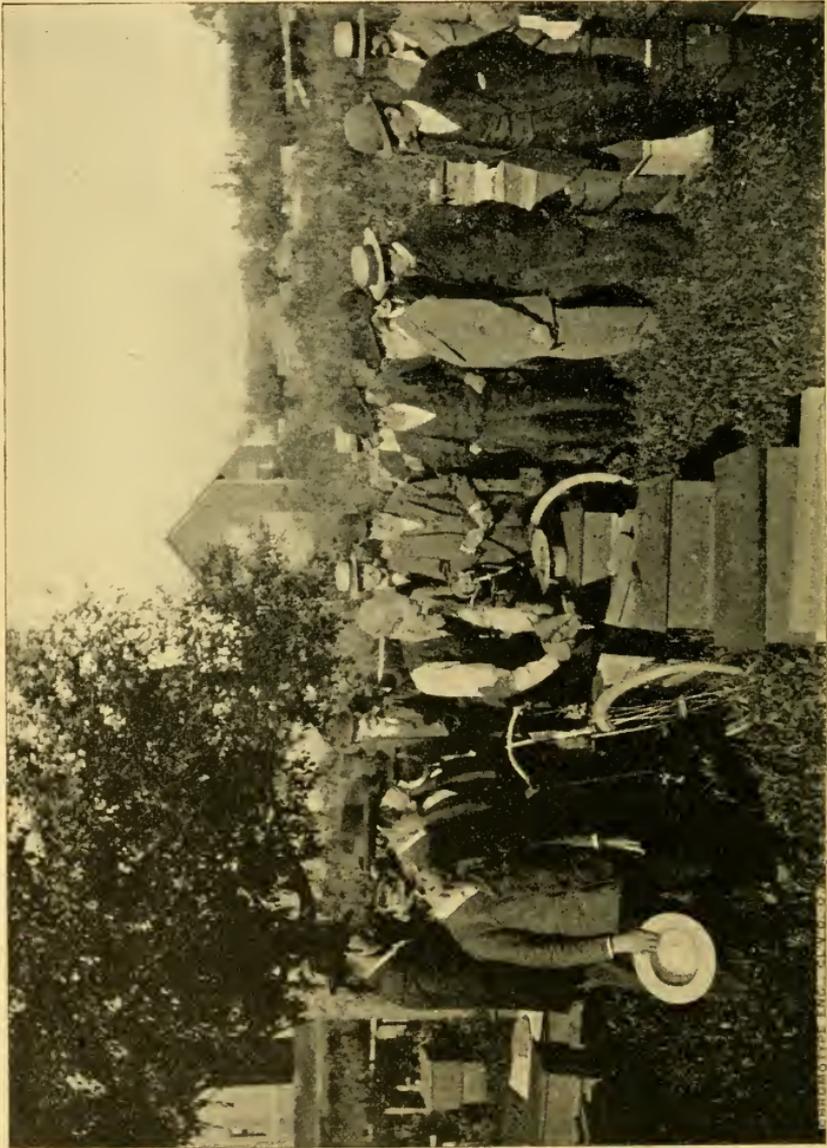

After I had taken the view shown herewith, I proposed that Mr. Greenfield "hare up" his bees, and while they were making a "scatter-

ation" among the bee-keepers I would take a snap shot. Mr. Greenfield readily did the "haring up"—yes, he did it to perfection—and the bee-keepers did the rest—performed the windmill act, jumped over hives—in fact,

"streaks" were so badly mixed up that one could not tell which from t'other.

THE JUNIOR REPUBLIC AT FREEVILLE.

After we had enjoyed ourselves at the Greenfield apiary a few of us paid a short

TOMPkins COUNTY BEE-KEEPERS AT THE APIARY OF LUTHER GREENFIELD, FREEVILLE, N. Y.

retreated in a hasty and inglorious defeat. My camera caught the whole performance; but, unfortunately, my shutter was not set for quick work; and the consequence is, that every man who started to run left a streak of himself, as it were, on the picture, and the

visit to the George Junior Republic, situated about half a mile from Freeville, and on top of a magnificent hill which commands a fine view of the surrounding country. The George Junior Republic—what is it? To many of you it needs no introduction. A certain Mr.

George, a young man of about 30 or 35 years of age, conceived the idea of taking up a lot of street waifs from the cities. He had no difficulty in securing this sort of material, you may be sure. By dint of hard work he managed to get men of means, and churches, interested. Some cheap buildings were constructed at Freeville, consisting of dormitories and other necessary buildings. The scheme was to organize these boys into a "Junior Republic." They were to have a president, vice-president, senate, house of representatives, police force, detectives, and all the other accoutrements of a well-equipped government. The scheme was carried out, and the boys not only liked the idea of bossing themselves, but actually governed themselves in an admirable manner. I was told that some of the worst boys made the best police officers. They are taught civil government, given an inkling of some of the great questions of the day, coin their own money, establish banks, make their own laws; arrest, convict, and carry out their own penalties. Contrary to what one might expect, the scheme has proven to be a grand success, both from an educational and a moral point of view.

I had often read about this institution, and it was a real pleasure to see the thing itself, and to shake hands with the founder, Mr. George, a man whom we must all admire.

Just as we were about to leave, one little chap (our guide) spied a button that was on Mr. Niver's coat, which bore the words "Single Tax" upon it. Cocking his eye at the button he turned and said:

"What's single tax?"

"That's too big a question," said Mr. Niver. "I could hardly answer it now. But I suppose you could tell us all about free trade and the tariff?"

"You bet," was the response.

---

## THE NEW SECTION AND FENCE.

Comments and Suggestions.

BY DR. C. C. MILLER.

It is not always easy to get at the real merits of any new thing until the time comes when it can hardly be longer said to be new. On the one hand, some are so enthusiastic about it that they see merits that exist only in imagination; and on the other hand there will be those who think they clearly foresee grave evils sure to result from the adoption of the new thing—evils which never come to pass. As an illustration, I may refer to the introduction of comb foundation some years ago, and a still more marked case of recent date is the drawn foundation.

Now comes a fresh candidate for popular favor in the shape of a no-bee-way section with its accompanying fence separator. It seems a little strange that so far the only words spoken of this innovation are words of commendation. Possibly the time for adverse criticism is not yet. Certainly you, Mr. Editor, have presented the merits of the case not only strongly but enthusiastically. If it's a

good thing, you have a right to be enthusiastic.

If you will allow me, I should like to discuss the matter from my standpoint—not by any means from a disinterested standpoint, but from the standpoint of one deeply interested. To get right down to the bottom, the quest on with me is whether the change will put more or less money in my pocket in the course of the next five or ten years. And I take it that, in the long run, you and I are not apart in that; for in the final analysis, whatever is a good thing for me as a honey-producer is a good thing for you as a manufacturer.

On page 817 you enumerate reasons that have induced you to make the fence and the no-bee way section a part of the regular hive-equipments. That is equivalent to saying those are the reasons why comb-honey producers should use them.

Your first point is that, in the long run, the fence separators are cheaper than the old ones. If that point is fully settled, you have pretty well settled the whole question. I don't know that you are wrong about it, but I'd like to be more sure you are right; for it is one of the points of most importance. You say the fence lasts for years, while the old separator, after being used a year, had to be discarded for a new one. I confess I don't see why the fence will last any longer than the plain separator. The old separator will last for years. I think you will find a good many so using them. As a matter of economy, some throw them away after one year's use because it costs more to clean them than to buy new ones. I think it will cost as much to clean a panel of fence as to clean a plain separator. If, then, I am to clean separators, and if it costs as much to clean one kind as another, there can be no economy in the fence unless I can buy it for less price than the other. The fact that it may be still cheaper to throw away the old separators and get new ones cuts no figure in the case, unless it be an argument in favor of the old separators. Now, if we know the price of the fence we can tell whether it will be economy or not. It may be economy for some and not for others, for all do not now use the same separators. It depends somewhat on the super. Some are now using separators that cost \$4.00 or more a thousand, while others have those which cost \$2.00 or less. However, if there are enough other advantages we can afford a little more expense, as we have done in many other things.

Carefully looking through your No. 2, I'm not sure I can raise any objection, although only trial can determine whether prettier sections can be produced with the fence. The only experience I have had in that line is with the Danzy super, which alternates the fence with the common separator. In some cases the sections are slightly ribbed opposite the spaces in the separator—not a serious detriment, but still a detriment. Possibly this may not occur with narrower spaces, and I have an impression that the sample of fence I saw in Chicago has smaller spaces than have the separators in the Danzy supers, for these last have spaces a little more than  $\frac{1}{4}$  inch. Any

thing that tends toward more free communication makes the bees more willing to enter, and, what is perhaps of as much consequence, more willing to remain—a point you do not mention. I suspect that, when a cold night comes, the more free the communication throughout, the less likely the bees are to desert the super.

Your third point, upon which you are not positive but hopeful, is that the fence will largely do away with passage-holes in the corners. I have just looked through the sections built in the Danzy super, every alternate separator being a fence. In every case the lower corners were unusually bad. The smallest holes were a shade less than half an inch long, but for every one as small as that there were three that were more than an inch long. Then I examined 12 sections filled between common separators, these sections having been thrown out of first class because not quite finished out, and I found 15 holes in the 48 corners, these holes being much smaller than the others. But it will not do to base a general principle upon so small premises; and it is only fair to add that the sections in the first case had only small starters at the top while the others were filled with foundation. Possibly this last might fully account for the difference; but it leaves the fact that, in some cases at least, the alternate separator being a fence, and only starters used, pop-holes in the corners will be bad.

The fourth point, that the fence is stronger, doesn't make any difference with me. I have never had any trouble on that score. Very likely it may be a fine thing for you who persist in using something inferior to a T super. It's a good thing to have the section-holder improved in some way.

Your fifth point is one that can not fail to secure attention, that the new sections will demand a better price. Whether that will hold good in all cases is a matter to be determined. You say the new sections look so much better. I put a lot of Danzy sections in two rows, the one showing the side next the fence, the others showing the side next the common separator. I was a little surprised to find less difference than I expected; and upon asking others, who knew nothing about what I was at, they didn't seem to see any difference till I called their attention to it. But isn't it possible that we have become so used to the leanness of the ordinary section that we are no longer impressed by it? I remember when I first used separators that I felt disappointed in the appearance of the sections as compared with sections without separators: and I distinctly remember, in a convention, James Heddon arguing against the use of separators, saying the sections had a lean look; and he threw a lot of meaning into that word "lean," as he drew it out to some length.

But whatever else may be said, if it remains a fact that the sections in question sell more readily or at a better price, then we can hardly afford to do without them. For if there is any advance in price at all, it is very likely to more than offset the small additional cost. We have testimony from more than one source

that such sections do sell better. Until there is rebutting testimony, we must give this some weight.

I suppose I shall shock you by saying that I don't see much weight in your sixth point. It is true, as you say, that "it is not an easy matter to clean out the insets of the ordinary old-style sections." I don't want to clean them out. They don't need it. "You know better?" Hold on now, and don't get excited. I didn't say your sections don't need it, for they do. But mine don't. You see, in a T super there is nothing touching the insets, so nothing to invite bee-glue into cracks. For you, no doubt, it will be an improvement of some consequence. Any thing that helps to obviate the defects of the section-holder will be a good thing for those who have nothing better.

Your seventh point holds good for those who use section-holders. Any thing to make their burdens lighter should be welcomed.

Point eight is worth figuring on—any thing that saves money in direct outlay. And I confess that, after a little figuring, it looks more important to me than it did. Take the popular 12-lb three-row case at \$7.00 per hundred. One hundred cases will hold 1200 ordinary sections, or 1500 of the new sections; 1200 of the new sections will take 80 cases. There's 20 cases, or \$1.40, saved on every 1200 sections, or on every hundred cases one has to have in the old way. Let's see what that will do toward evening up on the separator business. It takes 5 separators in a 24 section super. That's 1000 separators for 4800 sections. As we saved \$1.40 on every 1200 sections, we'll save \$5.60 on 4800 sections—that is, the saving on cases will give us \$5.60 to apply on every thousand separators. Say—why don't you tell us something about what the fence will cost? If you can furnish it at an advance of no more than \$5.60 per 1000 over the price of the old separators, then we'll make money by using it, even if we can get no more in price for our honey. For the \$1.40 isn't all we save on the 1200 sections. There's the making of the cases, the extra time handling and weighing, and that amounts to quite a little when one is rushed to get the crop shipped.

Probably you think I'm trying to find a good deal of fault with your new arrangements. Well, you see if some one didn't do something of the kind you'd be so set up that no one could live with you. But please don't resent it to such a degree that you'll say you can't furnish fencing that will fit T supers. For fear you should, I'll just mention that, in some cases, the saving of room will be quite an item. I mean the room the honey will take after it is in shipping-cases. And another item is that sections with the inset are liable to have the comb injured when standing in a case or on a table, by means of the side of another section being shoved against them. With the new section this is entirely impossible so long as both sections sit flat on the bottom.

By way of a parting word, I may say that the new sections will give some occasion to grocers' clerks to indulge in profanity. What

kind of a chance is there to get the first section out of a case when all the space is filled up, and no room to squeeze your thumb nail between the tops of the sections?

[Doctor, you haven't read all of GLEANINGS. On page 828 you will find the cost of the new fence stated. While it is true it will cost more than the old-style plain separator, it will last longer and will be as cheap or cheaper in the end. It is also stronger and more durable. But right here you stick in a question-mark. The ordinary plain sawed separator is made of one strip of wood less than  $\frac{1}{16}$  inch thick and  $4\frac{1}{2}$  wide. There are no cleats—in fact, there is nothing to stiffen it; and the constant handling of these, in and out of supers, has a tendency to break more or less of them; and the entire lack of stiffening causes some to curl and warp, rendering them useless. The new fence will be stronger than the old separator, just as a panel door is stronger than one wide door of the same width and length of one board, or as a cable made of strands of wire is stronger than a rod of iron of the same diameter. The new fence is made up of four slats and eight cross-cleats. If there is a slight tendency in one slat to twist or warp, that tendency will be counteracted or corrected by the next slat, and by the cross-cleats binding the whole four together.

With regard to the matter of scraping or cleaning, that will be much simpler with the fence than with the old separator. All that is necessary is to scrape the cross-cleats—an operation that needs to be done only once in two or three years, if I am correct.

As to the third point, regarding corner holes where you also raise a question-mark, I might say that I looked over a thousand pounds or so of Morton's honey—that is, I picked up sections at random from different supers and different places; and the remarkable part of it was that there were not any corner holes in any of the honey, so far as I can remember. This seemed to me very significant; and after I arrived home I fell to thinking about it more and more, especially when friend Danzenbaker showed me some of his slat separator honey. I looked over quite a lot of it, and in appearance it was about the same as Morton's.

With regard to the better appearance of the honey in plain sections, I am rather of the opinion that, if you will place that same honey, one lot in one shipping-case and one lot in another, behind glass, your women-folks will detect the difference. I have shown, to quite a number, the two cases that were illustrated in GLEANINGS, and the verdict has been every time that the honey in the plain sections looked better; but for what reason the observers could not say, as they were not experts in judging honey.

So you do not see any weight in my sixth point, namely, the advantage of the plain section in point of scraping and stain? The best way to convince you would be to take you through York State with me, where propolis is smeared over every thing. There are some localities where honey has to remain on the hive for a considerable time, because the flow,

while continuous, is very moderate. It is under such conditions that the insets of the old-style sections are badly stained.

While the matter of scraping may not be of any great importance with you, I am sure that, with 99 other bee-keepers, it means much.

We expect to be able to furnish fences for T supers and every other sort of super; but in the case of irregular or odd sized ones, of course a corresponding price will have to be charged.

With regard to your last paragraph, I grant it seems as if the new plain section would be more difficult to remove from shipping-cases; but the fact is, all shipping-cases should be provided with a follower and wedge, both for safety in shipping and for convenience in taking irregular sizes of sections. For example, our regular 24-pound shipping-case, by the use of the follower and wedge, or by the omission of either one or both, is adapted to take either 7 to the foot,  $1\frac{1}{2}$ , or  $1\frac{3}{8}$  sections, or even two inches. Well, then, when the grocer receives his cases of  $1\frac{1}{2}$  sections, all he has to do is to remove first the wedge, and then the rest is all easy; and speaking of wedges reminds me that twisted paper stuck in between the side of the super and the follower is the very best form of wedge that can be devised. It answers as a very nice cushion as well as a wedge.—ED.]

#### BEAN HONEY AND BEAN-GROWING.

BY C. A. HATCH.

To the average bee-keeper of the Eastern States, bean honey seems to be a myth—one among the many conjured up in the fertile brain of a Pacific-coast resident; and talk of bean-fields suggests to him only the garden-patches of his neighbors, or possibly a field of an acre or so grown by some ambitious one; but to think of a farmer putting his whole farm into beans, and lima beans at that, is unheard-of rashness. But here in California a good many things are possible that in the East would be quite impossible. Not only do farmers plant their whole farms to beans, but very large farms at that. One ranch near Ventura has 1900 acres, mostly in beans. The crop of this one ranch was 19 carloads one year. I saw 10 two-horse teams cutting, and 25 men shocking beans on their ranch this year, at one time.

How would it seem to see rows of lima beans one mile long? Impossible! you say; can not get poles enough for so many. But there are no poles used, and the large running lima is the kind grown, too, mostly. Some few Burpees are grown, but the large kind give the best satisfaction.

Ventura is called the bean county, and rightly, for three-fourths of the beans grown west of the Rocky Mountains are grown within her borders. Other parts of the State grow other kinds, but Ventura stands at the top for limas.

Thirty thousand acres is about the amount planted this year, which is 10,000 acres less than last year. The crop last year amounted to 1700 carloads. One thousand pounds is

called a good crop; but 2500 pounds has been grown on one acre without irrigation.

The beans never, as a rule, have a drop of rain fall on them from the time of planting to harvesting. The moisture in the ground, and the ocean fogs, furnish all the moisture; no rains to hinder cultivation or stop harvesting; but weeds grow all the same, rain or no rain, and cultivation must be prompt and thorough.

The beans are planted in drills about three feet apart, and 10 to 12 inches apart in the row, by a machine putting in three or four rows at a time. Cultivation is done by horse power, and but little is done by hand; but if weeds get into the rows, hand-hoeing is necessary, for few weeds are allowed to grow to take moisture from the main crop; and after the beans are cut and cleaned off, a sheep would almost starve on 100 acres, so clean are the fields kept.

Harvesting is done with a sled-like machine having two knives extending in and sloping backward, one from each runner. Each knife cuts one row, and an arm of iron placed just back of the knife throws the two rows together. Men follow with forks, and bunch the beans, where they remain until hauled to the thrashing-floor or thrashing-machine.

Thrashing is done in two ways—by a thrashing-machine or by tramping out with horses or "floors" prepared by smoothing off a piece of clay ground, wetting it so as to make it soft, then pounding until hard and smooth. In this method a disk harrow is frequently used to draw over the beans, one man following close behind the harrow and horses, with a fork to loosen, and toss the vines toward the center of the track around which the horses move. When enough are tramped out, the rubbish is cleaned out by a "cl aier"—a kind of fanning-mill suited to the business.

All beans are handled in gunny sacks, which go with the beans when sold; in fact, all kinds of grain, potatoes, and every thing that can be sacked, is put into these same sacks, which, by the way, are the source from which comes most of the smoker fuel used by the California bee-keepers.

Bean honey is white and of fine quality, but not positive in flavor, like clover or basswood. It never gets as thick as sage honey, and is prone to candy quickly.

The honey crop from this source is rather uncertain, as it seems to be very sensitive to weather conditions; too much sunshine dries the blossom, and hence dries the honey; and too much cloud and fog prevents the bees working, even if there be honey. This year the bloom was abundant, but the right conditions of weather seemed to be lacking. Just what those conditions are, it is hard to tell.

The greatest benefit to be derived from this source, it seems, is to make it a source of food supply in years of failure in other honey-plants; for, no matter how good a location one might have for bean honey, its uncertainty and shortness of flow would hardly justify any one in running an apiary for that kind of honey alone. The very source of prosperity to the bean-plant (ocean fogs) seems to be honey-destroying to other plants. The fodder, or

bean straw, from lima beans, makes excellent feed for dairy stock; and horses, when accustomed to it, do well on it. The straw is baled and sold the same as hay.

Pasadena, Cal.

[Friend Hatch, you have given us several points of value to bean-growers here in the East. First, beans are a dry-season crop. I have noticed for years that drouth never seems to hurt beans at all, but rather seems to do them good when the soil, cultivation, etc., are as they should be. Again, the old-fashioned pole lima beans give more bushels to the acre, at least so I take it, than Burpee's bush lima. But they are so much less trouble here in the East I think we had better take the Burpees, even if we do not get so many, especially where we are growing them by the acre.]

Very likely your great bean-farms have been the means of bringing about the present low prices on all kinds of beans. We see California limas quoted at 3 cents per pound. That would be less than \$2.00 a bushel. I have often wondered why these California limas would not be just as good to plant as seed beans that cost from four to five dollars a bushel here in the East. Has anybody tried it? And I wonder, too, why beans would not succeed in any desert land where it never rains at all. Your suggestions in regard to the ocean fog perhaps hit the point at least partially.

Finally, if it is a little discouraging to the grower to have beans so cheap, it is a great blessing to the hungry and starving people in different portions of this world of ours. I have been told that a pound of beans will keep up a man's strength longer than a pound of any other grain or vegetable, or any sort of meat. I hear just now they are talking about getting beans to Alaska, to save the starving miners. We are very much obliged to you for what you tell us about bean honey. It seems that the bee-keeper is not always absolutely sure of a crop anywhere on the face of the earth, even where there may be thousands of acres of beans, alfalfa, or white clover right in bloom.—A. I. R.]

## LARGE ENTRANCES TO HIVES.

Especially Adapted to Wintering.

BY THADDEUS SMITH.

When I was a boy, some 55 years ago, my father kept quite a number of bees. It was, of course, before the invention of movable-comb hives, and the bees were in the old-style box hives. At that time the bee-moth was very numerous, and it was supposed that the moth-worm destroyed many colonies of bees; and hence inventors turned their attention to making moth-proof hives and patent moth-traps, which were offered to bee-keepers as sure remedies against the ravages of the moth.

My father was an experimenter in this line. The worms were found in large numbers under the edge of the hive where it rested upon the bottom-board, where they had taken refuge when dislodged from the comb. I was re-

quired to go around to the hives early in the morning, raise the hive, and kill the worms. Chips were placed about the entrances for the worms to hide under so that they could be killed. He noticed that the worm, in making its web or cocoon, cut away some of the wood near it and worked it into the cocoon. He reasoned that, if they had no hiding-place, and no wood to form their cocoon, they would either die or be destroyed by birds and poultry. Acting upon this idea he raised the hives  $\frac{3}{4}$  inch above the bottom-board by driving a big fence-nail in each corner of the hive, leaving the ends projecting downward  $\frac{3}{4}$  of an inch, and, removing the bottom-board, put each hive upon a smooth flat stone. I don't know that this was an effectual remedy for the moth, but it gave the bees a good chance to carry them off, and we did not have to kill the worms any more; and it is a good case of a large entrance. This all-around entrance was never closed or contracted, winter or summer, and, so far as I know, the bees never suffered from too much ventilation. I do know that many of these hives remained in that position from 8 to 10 years without change. I never knew loss from wintering unless there was a deficiency in honey. How about the difficulty these bees would have in getting up into the hive? Well, I never saw them climb the four iron stairways, but "they got there all the same."

Pelee Island, Ontario.

[I have yet to hear of one bad thing against large entrances; and, on the other hand, we are getting letters every day indorsing them. In a year or so we shall all wonder how beekeepers *could* be so stupid as to get along with small entrances for so many years. One reason, I think, for making the entrance only  $\frac{3}{8}$  deep was to keep the mice out. But what does the mere matter of mice amount to in comparison with the other great advantages of better ventilation, prevention of bees loafing on the outside during the height of the honey-flow, and, to a considerable extent, the reduction of swarming? Mice! They ought to be trapped, or held in check by cats.—ED.]

## A NEW STYLE OF BOTTOM-BOARD.

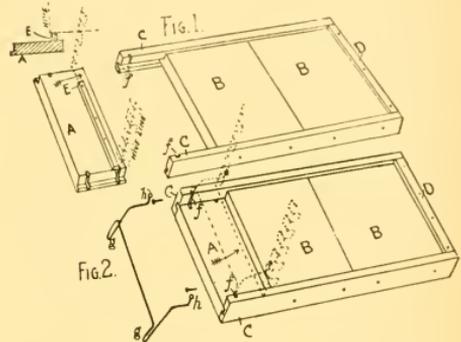

An Ingenious Idea.

BY W. A. CAMPBELL.

*Mr. Root*.—In reply to your favor of Oct. 9, offering to illustrate my new bottom-board in GLEANINGS, I shall try to make plain the manner of its construction and use.

Fig. 1 shows a bottom with alighting-board lying in front. The boards B, B, are joined together with  $\frac{1}{2}$ -inch lap. They are each  $9\frac{3}{4}$  in. wide by  $12\frac{1}{2}$  long,  $\frac{7}{8}$  thick, with tongues on their ends,  $\frac{3}{8}$  in., let into grooved side-cleats, C, C. The side-cleats are  $\frac{7}{8} \times 1\frac{3}{8}$  in.,  $2\frac{1}{2}$  in. long. D is a strip  $\frac{3}{8} \times \frac{7}{8}$  in.,  $12\frac{1}{2}$  in., nailed to B. A is the reversible alighting-board, by means of which three sizes of entrance may be had. It is  $3\frac{3}{4}$  in. wide, with projections on ends similar to boards B, B, but a trifle less, that it

may slide freely in grooves. If, in Fig. 1, board A is pushed directly into grooves in cleats, C, C, it gives the regular  $\frac{3}{8}$  size of entrance as in the Root bottom-board; but reverse ends and slide in place, and the  $\frac{3}{8}$  strip nailed at E comes under the hive-wall, and contracts entrance to  $\frac{3}{8} \times \frac{7}{8}$  at E. Next reverse sides of alighting-board, as shown in Fig. 2, and you have an entrance  $\frac{7}{8}$  in. deep, opening right into space at ends of frames, and extending under their ends  $\frac{1}{2}$  inch, or to board B, thence a  $\frac{3}{8}$  space to D.

The wire device in Fig. 2 is designed to keep board A in place, and to hold the entrance-guard or blocks and wire cloth when bees are moved. The loops *g, g*, are slipped into holes formed by the junction of saw-cuts in end of board A with those in cleats, C, C, at *f, f*. The eyes, *h, h*, go against hive-wall, and may be secured with a couple of screws for safety in moving bees. For those who do not care to fuss with wire, two wire nails will hold the board to place.

The  $\frac{7}{8}$  entrance ought to afford ample ventilation for a large colony, and greatly facilitate the hiving of swarms. In hiving swarms I would remove the alighting-board and set the hive right on the ground.

If Mr. Danzenbaker would combine my reversible alighting-board with his reversible-bottom-board idea so as to give the  $\frac{7}{8}$ -deep side for cellar wintering he would have a bottom with a wide "range of adjustment" embracing many desirable features. However, in the South, where we winter on summer stands, I hardly think we need the  $\frac{7}{8}$  space under frames full width and length of hive. We need only to contract our entrances in fall, which may be quickly and easily done with my reversible alighting-board, whether the bottom-board be fastened to hive, or loose.

Cisco, Ga., Oct. 23.

[This bottom-board is very ingenious, and when it first came to our notice we were very much taken with the idea. Yes, we almost thought of adopting it; but we came to the conclusion that a deep space of  $\frac{7}{8}$  inch under the whole brood-nest, as afforded by the Danzy bottom-board, was very important—almost as important as a deep entrance. Then it seemed to us also that the Danzy board would be

about as easily reversed as this entrance-strip. For these and other reasons we decided on the Danzy for 1898.—Ed.]

### THE MARKINGS OF QUEENS AND DRONES.

#### Unusual Results in Breeding and Introducing.

BY A. NORTON.

*Dr. C. C. Miller:*—You may answer this in GLEANINGS:

Is it not generally stated that you can better tell of the purity of a queen's mating by her queen progeny than by her workers—that is, that her young queens will more surely be striped if they are not pure Italian, while her workers may be very yellow? I have seen such statements, though I believe the Roots lay much stress on uniformity of workers and less on queens. But what do you think of this? I have a Carniolan queen from a pure one that I got from the East—a fine tested one. My own drones were golden Italians. Many colonies of black bees are near by in hives and trees; and one neighbor, 1½ miles off, has Italians, blacks, and all grades of hybrids. This young Carniolan queen's workers are, about two-thirds of them, black, without a sign of yellow, and about one-third of them yellow, showing generally three bands. When her bees first began hatching out last summer I thought she had mated with one of my five-banded drones. But when I see now the preponderance of bees that are all black, I wonder if she did not meet a drone having black and yellow blood mixed. Having another colony to which I wanted to give a queen at once, I recently gave them this same Carniolan, and sent east for an Italian to replace her in the mixed Carniolan colony. As said queen was long in coming, I let the first young queen hatch out that the virgin or bees might make surer work than I would of destroying the other cells. When the queen came from the East I destroyed this virgin, and found her to be as yellow, clear to the tip, as any golden Italian virgin I ever saw—no, but almost as yellow. She would have passed for an A1 golden-yellow queen.

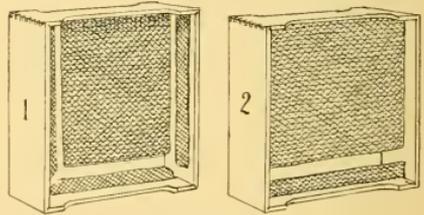

2. Would you think from the workers that the mother-queen met a pure or part Italian drone?

3. Do you consider the yellowness of the young queen as somewhat remarkable?

4. Is the following a strange instance for a dry time when no honey had come in for weeks? Colony No. 1 was queenless, and had been refusing a five-banded Italian queen from the East for several days. Colony No. 2 was but three or four feet away obliquely—or to the left, and behind No. 1. The hybrid queen of No. 2 had been killed a few days (only four or five days), and when I killed her I could not see a sign of eggs or brood in any stage in the colony. It was dry, and but few colonies were breeding any. One afternoon, just at sunset, I gave No. 1 a thorough fumigation with tobacco smoke, and released the queen they had been so persistently refusing. Just before dark I searched the combs,

but could not find her. Every day thereafter for about six days I searched carefully, but couldn't find her, dead or alive, in the hive or on the ground. Finally, having need for some reason to open No. 2, I found therein a fine bright yellow queen (looking much like the one I thought I had lost), and brood nearly ready to seal, as well as eggs, etc. Since then her progeny prove to be pure five-banded. When I released her in the hive, after the fumigating (I had taken her out during the process), she must have left at the entrance during the turmoil, taken wing, and alighted at the other queenless colony, which must have readily accepted her. Is not this a little remarkable for the dry time of year?

5. Concerning your remarks in both *American Bee Journal* and GLEANINGS about bottom starters, I tried them by way of experiment, and also starters on all four sides, to experiment, consisting of a top starter reaching to within an inch of the bottom starter, and short enough to allow of narrow (about ½ inch) starters on each side. The bees finished the sections about like this, leaving the same

gaps between the finished combs of honey as were at the outset between the pieces of foundation in the starters. Did you ever have any experience like it?

A. NORTON.

Monterey, Cal.

[To these questions Dr. Miller replies:]

1. Your first question is one which I hardly know enough to answer; but I the more cheerfully make the attempt because the large experience of the editors will enable them to correct any misleading statements I may make. I have always had the impression that not nearly so much reliance was placed upon the appearance of the queen progeny as on the worker progeny of a queen. If my memory is correct it was not an uncommon thing in the earlier years, after the introduction of Italians, to have it said that it rarely occurred, if ever, that a queen of Italian blood would duplicate herself with any degree of uniformity. Her royal progeny would vary in appearance, some of them lighter than herself, some darker, while her worker progeny would be so uniform that no one individual could be distinguished from the rest. It is also a fact, if I am not mistaken, that, among the queens imported directly from Italy, there is great variation, some of them being light in color comparatively (perhaps never so light as may commonly be found after a few years' breeding in this country), and others almost if not quite as dark as a common black queen. It seems to me, however, from the limited op-

portunity for observation that I have had, that, while an Italian queen may be as dark as a common black, there is a difference in the shades of the two—the Italian, while being as dark as the other, having a rich (perhaps mahogany) tint not shown in the black. And yet these imported queens of such different appearances would all have the same worker progeny, of the same color, and the same number of bands. Now, if there is no mistake about these imported queens of different looks being all of true blood, there would be nothing but what should be expected that their royal progeny should present differences of appearance, while the worker progeny would be true to type.

I have been called to account for saying that no one could decide from the looks of drones or queens as to the purity of the stock, but with my present light that is my belief. To an inquirer I made the reply that I could not give the distinguishing marks of a pure Italian drone; and when scouted at by a queen-rearer for giving such a reply I asked him to give me those distinguishing marks, but never got any reply.

2. If you mean by Carniolans the gray bees that were first known by that name, and that the workers that you say were black were the same gray black as the full Carniolans, then it seems pretty plain that an Italian drone was met, as is usual in the case of a first cross, part of the workers taking after one parent and part after the other. And with that view of the case the bright-yellow virgin would be nothing strange. But from your asking the question as you do, I suspect that you mean the black workers were unlike the regular Carniolan workers, but like common blacks, in which case I don't know enough to reply. The workers being part yellow and part black, the drone might be of mixed yellow and black blood, but in that view the Carniolan blood of the mother is left out of the count altogether, and that leaves me at sea. Perhaps the editor can make matters clear.

3. Probably unusual at least; and yet whatever will account for the presence of the yellow workers will account for the yellow queen. She took after her sire.

4. The usual thing would have been for the bees to ball the queen when you released her from the cage. She did the unusual thing by running away from her pursuers and escaping from the hive. After that she entered hive No. 2, where she stood a pretty good chance of being killed, for the bees would be more likely to kill a queen that had been caged and chased; and, it being a dry time when they were not anxious to have a queen laying, her chances of life were thereby lessened. Still, they were queenless, and the odd chance came her way. Quite possibly she would not have been so well received in No. 2 if you had had a hand in the affair. But they were left entirely to themselves; and, although they may have balled her at first, being left entirely alone they released her.

5. No, I think I never had a similar experience. The only way I can think of such a thing happening would be that honey was not

yielding very well, and as soon as the bees got well started on the foundation the flow became still more scant, making the bees finish out and seal over what they were already working on. I can hardly imagine such a case occurring in a good flow.

I may say, in passing, that I should consider it very objectionable to have an inch space between top and bottom starter—one-fourth inch at most, and then the bees will join the two starters together before the bottom starter has a chance to lop over or be gnawed down.

Marengo, Ill.

[I could adopt every paragraph of Dr. Miller's answer above as an expression of my own belief and experience, and, for that matter, I believe every queen-breeder could do the same.—ED.]

#### KEEPING SURPLUS QUEENS OVER WINTER.

*Question.*—Will you please tell us in next GLEANINGS how to keep surplus queens over winter? If it can be done it would be very profitable to have a few extra queens, to take the place of any that might turn up missing in the spring. I generally supply many of my colonies with young queens in the fall, killing the old ones; but if I could only keep the young ones over winter, I should prefer it to doing as I have done in the past. I am thinking of caging several in a queenless colony. Will that plan work well?

*Answer.*—It is very doubtful about your succeeding in keeping a surplus of queens over winter by the plan you suggest, especially if you live north of latitude 38°, unless on the Pacific coast. In my younger bee-keeping years I tried almost every way I could think up or hear of to keep a surplus of queens over till spring; but to make the thing a practical success, I was obliged to have a colony of bees strong enough to occupy at least three spaces between combs, at this time of year. With what is termed a "four-frame nucleus," and by setting the same, with about ten pounds of honey, in the four frames, in the cellar, as early as November first, I could generally succeed pretty well till they were set out in the spring, and sometimes they would pull clear through to the honey harvest and build up to full colonies; but it would happen more often that they would rapidly waste away during the last half of April and in early May, till they would die entirely, or be robbed out by stronger colonies. Where I could tell about failing queens thus early, I could kill them and unite these little colonies with their young queens with the colonies from which I killed the queens. But I could see little in favor of this, beyond what would have been had I killed the poor queens in the fall and done the unit-

ing at that time. Later on I was anxious for a surplus of queens in the spring, that I might fill early orders therewith, instead of taking queens out of my strong colonies, to the great disadvantage of the same, that customers might promptly get their queens. And, being extremely anxious along this line, I tried many plans, the one our questioner proposes being among the number.

With nearly all the plans tried I could get along very well till about February, when colonies having several queens caged in their hives would begin to get uneasy, and die with diarrhea, or they would consume all their honey in and about the cluster, and move off and away from the caged queens "to pastures new," leaving the queens to die in their cages. Then I tried little nucleus-boxes, such as most queen-breeders used in raising queens in the early seventies, the same holding three or four little frames six to seven inches square. I would see that these little frames had three or four pounds of honey, and only about bees enough to consume that amount before spring fairly opened, when I expected to feed them. Four to six of these little boxes were placed over a good strong colony, setting these little boxes right on the frames, and fixing it so the bees of the strong colony would, or could if they were so disposed, cluster all about the bottoms and partly up the sides of the boxes, providing a way for the bees in the boxes to get out without mixing with each other or with the colony below, should those dying of old age wish to do so.

The little boxes were now covered all over with woolen blankets, and a hood or cap put over all, when it did really seem that they might go through the winter all right, in a cellar whose temperature never went lower than 45°. But with a trial of some thirty or more in this way I got only two through to where they could fly in the spring, while the colonies over which they were placed were lost, or became so weak that they were of little value during the next season. From these and many other experiments, which it would be superfluous to describe, I was driven to the conclusion that nothing could be gained in trying to winter over surplus queens; and if early queens must be had to a greater number than could be spared to advantage from full colonies wintered over, the cheapest and easiest way was to purchase them from the South.

If any reader of GLEANINGS has found out a practical way of wintering over queens to a greater extent than one to each fairly good colony, I wish he would tell us how it is done. If queens can be so wintered that each apiarist could have one extra queen to every ten colonies during the months of April and May, it would be a great help to every bee-keeper in the land, providing that the wintering of such queens did not cost more than the results which could be obtained from them during the year. Hence the importance of any reliable information on this point. Don't be afraid to add any "mite" you may chance to have along any line of our pursuit, thinking it will be of so little value that it is not worth giving, for it is the little "kinks" that

give value to apiculture, when they are massed into one great whole.

"Fine building, sir," said a poorly dressed laborer to a man of fortune who was looking at a just-completed stately edifice in one of our large cities. "It took us many a year to bring it to completion; but now it is done it outshines any other building in this city."

"Took *you* many a year!" said the man of fortune, with a sneer in his tone; "what did *you* have to do with it?"

"I mixed the mortar, sir," was the reply; "and without the mortar that stately edifice could never have been completed. You may think me of no consequence; but by the grace of God I was able to add my mite toward the completed whole."

And just so with the structure of apiculture so far as it is now completed. Some have made greater "marks" than others; but we should never have reached the present heights had it not been for those who have "mixed the mortar," adding "here a little and there a little," till bee-keeping, during the year 1897, looms up as a stately edifice beside the small foundation laid a century ago. In helping each other we are giving "a cup of cold water" to some struggling brother; and the Master has said that the one who does this "shall not lose his reward."

PARAFFINE PAPER; HERMETIC SEALING IMPORTANT.

I see by GLEANINGS quite a controversy about paraffine. I had quite an experience with paraffine, not quite in accord with Danzenbaker, nor yet will it quite fit Dr. Miller's Straw on page 802. Reading Mr. D.'s article some time ago about paraffine it struck me as being rather nice. I would use it on my honey-boards for the hive I make (by the way, a hive I wouldn't give for the best dovetail ever made). I spread the paraffine on it hot, using a hot iron to make it penetrate the wood. Some of it accumulated in holes bored for the bees to ascend. On taking the honey from them I was rather surprised to find they had used the little clots of wax (paraffine) as though they were really beeswax, stretching it out into cells, thus convincing me they have no aversion to paraffine, but simply do not glue the parts together because they are already air-tight with paraffine. Dr. Miller's experience of finding glue on top of paraffine may be that, although he used paraffine, the two parts did not go together tight, therefore the bees made it air-tight with propolis.

You know, as well as any one, no doubt, that bees will have every thing tight. I am pretty sure that Danzenbaker is correct. Bees will use no propolis, provided made tight otherwise. Bees have no aversion to paraffine,

as can be proven by rolling some into foundation. It will be found that they will use it the same as wax. Join your honey-board to your hive-body and seal the two hermetically with paraffine, and your bees will certainly use no propolis.

LIFE L. ESENHOWER.

Reading, Pa., Nov. 25.

[We have tried foundation made with paraffine and of pure beeswax. While the bees will accept the former, it is very evident that they prefer the latter. If you put the two side by side you will see the difference.

With regard to tight sealing, I believe myself Dr. Miller lost sight of this point in his test of paraffine paper. If used at all it must be cushioned down *light* on the sections, otherwise it will be worse than useless. I am no "stickler" for paraffine paper, for, personally, I should prefer the bee-space over the sections, and the *cover* sealed down with propolis; but when the paper is used it should be applied as directed.—ED.]

#### USE OF PARAFFINE PAPER ON SECTIONS DEFENDED; GETTING PRIZE HONEY.

On page 734, Oct. 15, is an article by F. L. Thompson in which he condemns paraffine paper in covering sections in supers; and as Mr. Danzenbaker is invited to reply, and he seems to be playing clam to the music, I will say that, in my 15 years' experience in bee-keeping, and two seasons' experience with paraffine paper, with some 200 colonies of bees, for comb honey, I find a saving of several dollars, both in labor in cleaning sections, and better prices for honey produced by the use of the paper; and as I raise honey for the money, that is why I prefer to use the Danzenbaker section and paraffine paper in connection with his hive. Mr. Thompson says it was the combination of the paraffine paper with some other things that produced that prize honey, and that those other things are far more important. Of course, he is right so far as the honey goes, as honey gathered from buckwheat or other flowers that make black honey would not be prize honey, even with the use of the paper. But the paraffine paper will prevent propolis, to a great extent, in the entire super, as it retains the heat; and it is a well known fact that, the more heat there is in the super—natural heat—the less propolis. A proof of that fact is, as the season advances, and the weather gets cooler, the more they use.

The object of the paper is to retain the heat; and to fit snug on the sections I fit the paraffine paper and thin boards on the supers in the honey-house, and then take them out to the yard, and I have none of that fuss that Mr. Thompson speaks of. I would use it, even if I had to throw it away after once using it. The cost is small compared with the amount of labor saved in scraping sections. If Mr. Thompson has his bees in a good location, and will use the one-bee-way Danzenbaker section and cleated separator with the paraffine he will have no trouble in getting prize honey.

S. D. MATHEWS.

Hamilton, N. C., Nov. 17.

[If it is certainly true that there is less propolis when there is an air-tight sealing over the sections, then we must give more attention to that point. Who will corroborate or say it is not true? Let's have a lot of responses to this point.—ED.]

#### THAT HOOK ON THE SMOKER; A POSSIBLE IMPROVEMENT.

Say, Mr. Editor, that hook idea of W. L. Coggschall's, figured on page 779 is good; but just put the hook on the front of the barrel, as we have used it for the last ten years, and see how handy it is to hang on the side of the hive so that smoke can blow across the frames and keep bees quiet while manipulating. If put on the back of the bellows, as figured, it is necessary to turn the smoker around to have it in the right position for use. Doubtless you recollect occasions when having the smoker just ready to grab with one hand was a great satisfaction. We have used the hook this way on the old B. & H. smoker, and also on the new Crane. In the latter case it is simply a stout piece of hoop iron riveted on the barrel above the guard.

#### TWO CALIFORNIA CRANKS.

Los Angeles, Cal., Nov. 22.

[I don't know but you are right. I'll try one that way to see how it works and looks. Yes, there are times when one wants a smoker and "wants it awful bad;" and I have seen times when a second of time in grabbing a smoker would save a dozen stings. To be obliged to fumble after it, not knowing exactly where it is when it is wanted for instant use, is aggravating. But say, it just occurs to me that, if hooks were put on the fire-cup itself when the smoker was hooked on, the hive would be scorched and perhaps set on fire.—ED.]

#### BEEES GNAWING OUT BOTTOM STARTERS.

I see in *American Bee Journal*, page 726, an item in regard to furnishing beeswax to bees, with remarks by Dr. Miller and the editor of GLEANINGS pro and con. I used foundation in the honey-boxes this year, putting in nearly full sheets with bottom starters. The bees worked all right during the heavy honey-flow, and filled the boxes from top to bottom, doing very nice work indeed. But in the late harvest the bees took out the bottom starters or strips of foundation and stopped the combs where the top sheets of foundation ended. I suppose, as Dr. Miller says, they put the wax in the propolis, but I am not old enough in the bee business yet to say where the wax went to.

WM. H. EAGERTY.

Cuba, Kansas, Nov. 27.

[Putting "wax into propolis"—I don't understand you. I hardly think they would convert one into the other.—ED.]

#### A SPRAINED ANKLE; THOSE PLAIN SECTIONS.

GLEANINGS for Nov. 15 tells us of your passing here on that spurt just before coasting into Syracuse. Isn't it fun? I want to tell you some of my experience with a wheel, that

you may escape such an experience. I started to visit my apiary, 7 miles away. In dismounting in a spot too rough to ride I stepped on the edge of a rut and thought I had sprained my ankle. Now, here is something to tell your friends. In dismounting, never step off backward, as you can't see where your foot will alight; but let the wheel tip over after slowing up, when you can see where you are stepping. After doctoring a sprained ankle for four months I found I hadn't sprained my ankle, but had injured my foot. Now, after having my foot in plaster of Paris for two months, the doctor told me to-day to begin walking. The result is, instead of the nice start in bees I thought I should have, the bees are gone and I shall be in debt when I get so I can work again. I have had a long six months of it. I saw in a back number of GLEANINGS that Mr. Calvert had some of this kind of fun. Three years ago to-day I cut my other ankle with an ax while cutting limbs away from hives.

I am glad to see you using the section without a margin, as some here call them. Doubtless they are the coming section. I don't see how you are going to make them, but some around here made with one piece an exact duplicate of the other three, with a peculiar dovetail. Your italics at the bottom of page 817, first column, are right to the point.

IRVING KINVON.

Camillus, N. Y., Nov. 26.

[There is no difficulty whatever making one-piece plain sections.—Ed.]

#### A REPORT ENCOURAGING FROM THE GREAT NORTHWEST.

I have just returned from a long excursion to Eastern Oregon, Washington, and Idaho, with other merchants from Portland, who were out making the acquaintance of numerous customers, many of whom they had never seen. I had been over the country before, and so knew something of the extent and variety of resources; but to many of our merchants it was a revelation. It is indeed an "inland empire," and in all our traveling of 1700 miles we did not see a discontented or dissatisfied merchant. The crops were simply immense. The prices were good. The farmers have paid up old indebtedness, and have money to lend.

BUELL LAMBERSON.

Portland, Or., Nov. 23.

#### FOUNDATION FOR SHALLOW BROOD-CHAMBERS.

If two Dovetailed eight-frame hive-supers, each containing eight shallow well-wired brood-frames, were used for a brood-nest, could not extra thin surplus foundation be used in these frames in full sheets, and secure straight brood-combs comparatively free from drone-cells? If not, what is the lightest foundation that could be used with success?

Browning, Ill., Nov. 17. G. A. DYER.

[Extra thin would be a little too light; but what is styled thin super might answer very nicely.—Ed.]

#### A SPECIAL SCRAPER FOR SECTIONS.

I think scraping sections with a common knife is hard and dangerous (for the honey), especially in the fall, when they put so much propolis on. I inclose a scraper which I made,

which is quicker, and with it you can't jab the honey. You can see how it works. It scrapes the edge and top of the section at once.

JNO. N. PROTHERO.

Du Bois, Pa., Sept. 18.

[If we adopt the new (old) plain sections with no bee-ways, a common case-knife will be the best scraper after all. For the old-style section I have no doubt that your scraper is better.—Ed.]

#### HOW TO WINTER BEES IN A WARM ROOM; PARTRIDGE-HUNTING.

I have learned something about wintering bees that is new to me. I have taken GLEANINGS for 20 years, and have not seen my way mentioned. I have been testing the method for three winters, with good results; now for the way.

I put them in a wire cage 30 in. long, as wide as the hive, and as high; that leaves a playground in front of entrance. Then I set them on a tight floor, so there is no possible chance for them to get out; then put them in a warm room and give them water. I have a house made on purpose, and have a stove in it. I burn wood, and keep the temperature from 45 to 90. You will think, when I say 90, that they would die. Try one and see. Do not keep them that warm all the time. When I build a good fire the temperature goes up that high quite often. The reason they die in a room like a living-room is because of a want of water. I keep mine in darkness till the 10th of February; then give them all the light I can, so they start raising young bees; then there is no spring dwindling.

I should like to have you come and hunt partridges about a week. It will cost you nothing for bed and board. You would need a trained dog if you wanted to kill many. I see as many as 40 some days when I am going round my bear-pens. There are some bears and a few deer left here yet. I am 63 years old. I have killed 59 bears and 81 deer. If you would come for a hunt you could go with me to the traps, three miles out. If we failed to get a bear we could get some birds. I have found lots of bee-trees—some good ones and some poor ones. I found one this fall in Potter Co. in a basswood. The hollow was 12 in. at top and 14 in. at the bottom, or an average of 13 in., filled 11 feet—more comb honey than a barrel would hold. If you could see the chance they had you would not think they had done any thing extra.

ISAAC WYKOFF.

Cameron, Pa., Nov. 12.

[Your plan may work very successfully, but if carried out on a large scale it might be

pretty expensive. But it is interesting to know that bees may be wintered in a warm room, under certain conditions; and one of those conditions seems to be plenty of water.

But, say, I should like to go on a hunt with you; but work, I fear, will hold me down too close for such a luxury.—ED.]

THE PLAIN SECTION AND FENCE; QUESTIONS CONCERNING IT.

*Mr. Root.*—On page 744 you speak of the comparatively no-bee-space section and cleated separator. You have no idea how you interested me, as I have had more or less thoughts relative to cleated separators with bee-space openings ever since I read with so much interest what the late B. Taylor said in March 15th GLEANINGS, 1895. And now the comparatively no-bee-space section filled out within  $\frac{1}{8}$  inch of the edge has more than doubled the interest in the cleated separator. I do not know how I could succeed with them, but it seems to me it would be grand.

In order to have the same capacity as the  $1\frac{7}{8}$  scored section, would not  $1\frac{5}{8}$ , instead of  $1\frac{1}{2}$ , be the proper size, as each separator cleat reduces the width of the section  $\frac{1}{8}$  inch?

While I suppose the cleated separator and narrower section would work on the  $1\frac{7}{8}$ -inch section-holder, yet I think it would be much better to have the cleats go down between the section-holder, and rest at the ends on the tin bearing. If the section is narrower than the section-holder the bees will fill in propolis along the edge of the section—at least I think they would, as I have used straight slats for section-holder bottoms as wide as the narrow part of bottom of section, and on the edge of the wider part of section would be found propolis, gluing the section to the section-holder.

I did not receive the samples of drawn comb in time to give it a trial, but can see that it is a production of great mechanical skill. I think a  $\frac{1}{8}$  or  $\frac{1}{16}$  raised cell wall would be sufficient, and easier made and handled. I am glad to learn that it can be made with natural-cell bottoms instead of flat bottoms.

Did your staple for end bee-space at end of brood frames give good satisfaction the past season? That seems to be of interest to me.

It occurs to me that the one who boils down "beedom" for the *American Bee Journal* must stand by nearly all the time and stir, as it seems to be boiled down pretty thick, and yet not scorched.

J. W. SOUTHWOOD.  
Monument City, Ind.

[The cleats on the fences we are making are just exactly  $\frac{1}{2}$  of an inch thick. Assuming that the bee-space is  $\frac{1}{4}$  inch ( $\frac{3}{16}$ ) there will be one-third of the bee-space in the section; that is to say, the comb surface on the average will be  $\frac{1}{2}$  inch from a straight-edge lying across the edges of the plain section. If we made the cleats only  $\frac{1}{8}$  inch thick on the fences then the sections would have to be  $1\frac{5}{8}$  inches wide.

The fences will be made to go *between* the section-holders, and this will, of course, require that they (the section-holders) shall be the same width as the sections; viz.,  $1\frac{1}{2}$  in.

When the fences are designed for the old-style section-holders they will be made to go *inside* of the holders, not between.

Yes, th staple for end-spacer gave excellent satisfaction, and we shall use it for 1898.—ED.]

*N. A. W., Wash.*—We can give you no definite information as to whether locust honey candies quickly or not, as that which we have produced was sold almost as soon as it was capped over in the combs. The honey is not equal to clover, mountain sage, or alfalfa, in point of flavor; and in color it is a little darker than clover or basswood. We do not see any reason why you can not buy this as well as any honey, by sample. We have special mailing-vials for small samples of extracted honey. There is no reason in the world why you can not get a small sample by mail.

*J. J. V., Mo.*—1. The shallow extracting-frames,  $5\frac{3}{8}$  in., are a little handier to uncap than the whole-depth Langstroth frames. Where the seasons are short, or the honey comes in slowly, as it does in the majority of localities, a shallow extracting-super is preferable to one full depth. The latter is apt to discourage the bees, as it gives them too much room at a time to keep warm at the start.

2. A wood-bound honey-board provides the necessary bee-space above the brood-frames and between the super above. It is also at the same time stiffer and much more satisfactory in every way than the unbound zinc.

3. The ten-frame hive is not necessarily better than the eight-frame. It all depends upon the locality and general circumstances. Where one desires to run entirely for extracted honey, and the seasons are long, then the ten and twelve frame hives seem to be better; but in the North, where the seasons are short, and the honey-flow moderate, the eight will give as good or better results.

4. Comb foundation not used in the summer should be kept over winter in a room that will not go below a freezing temperature; and when it has been subjected to a freeze it should not be handled while in that condition. While freezing may not do it any harm, it certainly does not do it any good.

5. The bees should have only as many frames as they can cover comfortably just before cold weather sets in. The average colony of eight-frame capacity will take about six frames for winter; of ten-frame capacity, seven and eight frames.

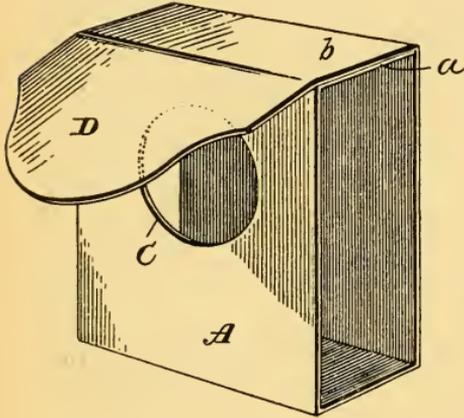

6. An ordinary Langstroth frame may hold anywhere from 6 to 8 pounds.

For further particulars in regard to these and other matters see our A B C of Bee Culture, and our catalog which we are mailing you, especially the last few pages. Prospectus of the A B C book is given on page 31.

THE DANZENBAKER SECTION-CARTON.

Mr. Danzenbaker has been turning his attention of late toward a cheaper carton than has hitherto been sold on the market. The one that he has devised is shown in the accompanying sketch. It perfectly protects the two faces of honey, and the top and bot-

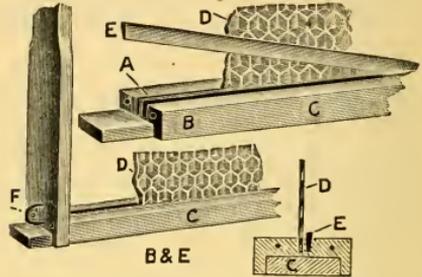

tom, but does not cover the ends of the sections. The section is slipped into the carton endwise; the flap D is folded over the opening, and that gives a view of the honey. Then a rubber band is slipped around the package. For the purpose of showing the honey the flap D may be lifted up, and the honey is shown from the opening as at C.

Just how far this carton may prove to be cheaper than the regular styles on the market I can not say; neither do I know whether the opening at C, with the cover-flap D, will prove to be of special merit. All these things will have to be laid before the unprejudiced bar of the consumer.

FASTENING FOUNDATION IN TOP BARS; THE SLOTS AND WEDGE METHOD.

For a number of years we have made our thick top-bars with a molded bead, the same as is illustrated on page 817. This molded edge forms an excellent comb-guide to the bees when no foundation is used, as well as an edge to which foundation can be fastened by means of the D'Isy foundation-roller. While the majority of our customers have succeeded in fastening the sheets to this edge by the roller method, some few seem to be unable to acquire the knack; and as there has sprung up within a year or so a demand for the saw-kerf and the wedge method, we have decided to make this feature, for 1898, an option, without additional cost, on brood-frames, whether of thick-top or of the Hoffman. The method

that we have adopted we regard as an improvement over some that have been put on the market, and is no hing more nor less than an old method used by the English bee-keepers for years, and for whom we have made thousands and thousands of frames embodying the feature.

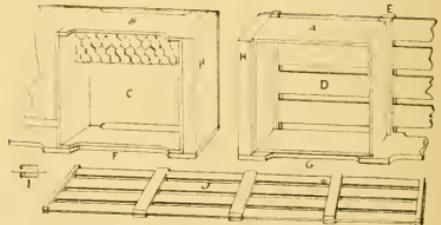

The accompanying engraving shows just the idea. There are double saw-cuts  $\frac{1}{4}$  inch deep  $\frac{1}{2}$  inch wide, running exactly parallel, and separated by a film of wood about  $\frac{3}{8}$  inch thick. One of the saw-cuts (the one to receive the foundation) is exactly in the center of the top-bar. The method of fastening is to slip the sheet, as at D, see engraving, into the saw-cut. The long wedge-shaped strip of wood, E, is then driven down into the other saw-cut, wedging the aforesaid dividing-film of wood tightly against the foundation, thereby making it fast. The engraving will make the thing perfectly plain.

The only objection I can see to this method—and it may prove to be quite a serious one in the future—is that foundation will probably be made with deeper side-walls than at present. It may not be practicable to make the saw-cut fit the variety of thicknesses of the different foundations on the market. The saw-cuts as we make them at present are adapted to the use of sheets of ordinary medium or light brood foundation.

FENCE FOR OLD-STYLE SECTION-HOLDERS.

Some of our subscribers have not understood how the plain section and fence could be used in the old-style section holders, especially when the plain sections are  $1\frac{1}{2}$  inches and the

old sections were  $1\frac{1}{8}$ . By consulting the accompanying drawing, I think the idea will be made plain. A E H D shows the plain section in the old section-holder. The width of the sections is exactly the width of the inset

at G. As the plain section is narrower by  $\frac{1}{4}$  of an inch than the old section, there will be  $\frac{3}{4}$  on each side to fill up. And this space is filled by cleats on the fence that are exactly  $\frac{3}{4}$ . B C H shows the old-style section-holder and separator, and a comparison of this with the other will make the idea plain. The artist has made a mistake. The cross cleats should drop down from the top slat by  $\frac{1}{4}$  inch, and the slats themselves should project beyond the end-cleats a distance equal to the thickness of the section-holder end.

#### NO-BEE-WAY SECTION FOR THE DANZEN-BAKER HIVE.

By the way, Mr. Danzenbaker wishes me to announce that his hives for 1898 will be fitted with no-bee-way sections. He writes me that he is glad that I have come to see the value of the double-cleat separator and the plain section, and is now mean enough to insinuate that he "told me so," but that I couldn't or wouldn't see the advantage of these things last year. However that may be, I was rather under the impression that he was a stickler for the *one-bee-way* section, and that last fall when I was arguing for *no bee-ways* he would not take them as a gift. But all is well that ends well. We are both in the same canoe, and are now looking for fair sailing.

S. A. NIVER, at the close of one of his letters, writes: 'I am about to start over my honey-route again—this time to collect bills. Selling and collecting are two entirely different matters.' Mr. Niver has given us valuable information on selling honey. Will he now also tell us something about collecting? Does he go at his "poor pays" rough shod, or does he give them honeyed words and sixty days more time? By the way, I should like to hear from others of our readers who are successful in getting their pay for every pound of honey sold. A few little hints on this subject will prove very helpful.

#### HONEY-LEAFLETS AGAIN; KEEP THE BALL A ROLLING.

I HAVE already spoken of the fact that we are inclosing in every one of the letters that go from our office a copy of our honey-leaflet. I have also mentioned how it got into the hands of a government official, and of the liberal extracts that were made from it in one of the great dailies of Columbus, Ohio. This morning a clipping was laid on my table, taken from the *Cleveland Leader*. It related to the value of honey as food. As I read down the column it seemed strangely familiar, and it finally flashed through my mind that it was all from our honey-leaflet. The reporter had made some variation, and had himself dwelt

upon the fact that honey is cheaper than butter, and that it never becomes rancid, etc.

How the *Leader* got hold of the matter I don't know. If we can only get into plate matter the material that Dr. Miller has so carefully prepared, and into the great dailies of the country, it will do a world of good to the industry. There is nothing in the subject-matter of the leaflet that advertises supply-dealers. It simply tells how good honey is, and, of course, will create a demand for it.

#### THIEVES AT OUT-APIARIES, AND HOW TO DEAL WITH THEM.

OUR out-apiary is being tampered with again by thieves. Several hives have already been looted in the last few days. When the weather is warm, and the bees are able to use their wings, the apiary is not molested; but as soon as it turns cold, and the bees are semi-dormant, then the depredations commence. We have made up our minds to stand it no longer, and have therefore posted, in several places, especially at the out-yard itself, the following:

\$100 REWARD.

The above sum will be paid for the arrest and conviction of the parties stealing our honey and otherwise tampering with the bees at our apiary a mile and a half north of the American House, on the pike. For particulars apply to

THE A. I. ROOT CO., Medina, O.

Almost before the bills were out, one man said he'd half a notion to go after that hundred dollars, and I hope he will. Even if no one secures the reward, the *effect* will be good.

When I visited Mr. Elwood, seven years ago, I saw he had notices of this character posted up in the vicinity of his yards, and I believe the moral effect of it was such that the would-be thieves let his bees and honey alone because they knew the temper of Mr. Elwood; and that, if they were once convicted, he would see that the utmost penalty of the law was imposed. In this State, at least, the penalty for stealing honey, or for tampering with hives, is very heavy; and if we succeed in apprehending the guilty parties we propose to let the law take its full course.

#### THE U. S. B. K. U. ANNUAL ELECTION.

The following letter has just come to hand, and will explain itself:

As the annual election of the Board of Directors is approaching, I assume that nominations are in order. It seems strange that the great State of New York is not represented in that body. I have not a list of the members, but I think I am justified in saying that New York has as many members as any other State, and a great many more than some States that are represented in the Board of Directors.

I understand the U. S. B. K. U. does not claim to be a representative body; but if you want to make it a success it will not do to ignore the greatest State in the Union. If any State should be represented by one or more in the Board of Directors, that State is New York. I nominate P. H. Elwood, of New York, for a Director of the U. S. B. K. U., and urge his election.

W. F. MARKS.

It is true that York State, one of the greatest honey regions in the world, is not represented in the new Union, and it certainly ought to be. While I happen to be a member myself of the Advisory Board, I have always felt that it would be better for some one in the *field* to be in that position. While it is prob-

able that my name would not be again reconsidered, yet if there are any of my friends who had thought of voting for me again I would consider it a personal favor if they would turn those votes over to Mr. Elwood—a solid man in many ways—one who is engaged in bee keeping on a most extended scale, and one who appreciates most thoroughly some of the difficulties and problems that confront bee-keepers. I do not like to do electioneering or wire-pulling; but I do hope Mr. Elwood will be chairman of the Board of Directors for 1898.

Perhaps some of my friends will think I ought to go on again; but occupying the position I do on GLEANINGS, I can offer my great chunks of wisdom (?) just as well as if I were a member of the Board itself, and I can assure my friends that my interest in the Union will be just as great as though I were an active officer of the same. I feel that, with all my other duties, I have not the time to give the Union such intelligent attention as an officer should. Hip—hip—hurrah for P. H. Elwood!

#### A FUNNY MISHAP.

Many of our English cousins are enthusiastic bee-keepers, and they set as great value on their choice queen-bees (or even greater) as do our friends here in America. During the past season, so we are told, one bee-keeper over in England arranged to send to a brother bee-keeper a choice and valuable queen; and the agreement was, when it was ready to mail, a telegram was to give notice to the recipient that she was coming. Imagine the surprise of the telegraph operator when he received the following:

"The queen will be at your place on the 5 o'clock train. Have every thing ready for her on her arrival."

The operator, it seems, knew nothing about queen-bees, and at once jumped to the conclusion that the Queen of England, by some sudden arrangement he could not understand, was to grace their little town with her royal presence. Imagine the surprise and disgust of the good people (who gathered from every direction) when the express agent held up a wire-cloth cage containing a *queen-bee*! The account does not state where the telegraph operator was with his telegram about that time.

A. I. R.

#### APICULTURAL JOURNALISM.

FRIEND Hutchinson, of the *Bee-keepers' Review*, says he is proud of GLEANINGS, even if it is not his journal. Here is the generous compliment he pays us:

GLEANINGS for Nov. 15th is an unusually fine issue for even that fine journal. I have counted the engravings, and there are fifteen, while the reading is bright and sparkling, and "up to date." I am proud of GLEANINGS, even if it isn't my journal.

On another page of the same number Mr. Hutchinson gives the *Amer. Bee Journal*, another competitor of his, this *well-deserved* compliment:

An editor will notice editorial work on a journal similar to his own quicker than will any one else; and in this connection I wish to say that I believe no bee-

journal shows more careful, conscientious editorial work than does the *American Bee Journal*. By this I do not mean that it contains a large amount of editorial matter, because it does not; but there is an undefinable something about a paper that tells to the practiced eye when things have been "licked into shape," or whether they have been thrown together after the "slap-dab" style. Bro. York does not claim to have had much experience as a bee-keeper; but he is bright enough to bring to his aid those who have; and I doubt whether the *Bee Journal* was ever of much more practical value than at present. Speaking of work, I believe that Bro. York does not have a large force, yet he gets out a weekly, and I know that he must have to put in hours of work with which we monthly fellows have no acquaintance.

How different the spirit of these utterances from those displayed by the editors of some other rival journals in other pursuits! Only the other day, in reading my bicycle journals I could not help noting the way the respective editors of those periodicals slung mud at each other, and especially how they praised their own journals, and ridiculed those of their competitors. Will Bro. Hutchinson lose subscribers from his own list who will go to the *Bee Journal* or to GLEANINGS? Not at all. I am of the opinion that the average subscriber admires that kind of spirit, and he will stay by the editor every time who shows that spirit of brotherly love—"in honor preferring one another."

#### MISTAKEN IDENTITY AT BUFFALO; THE BORES AT CONVENTIONS.

THE following item appears in the weekly Budget, which, by the way, is always interesting, in the *American Bee Journal*:

Mr. D. W. Heise, one of the most respected and gentlemanly Canadians at the Buffalo convention, reports in the *Canadian Bee Journal* that at that meeting he was several times taken for Mr. Ernest R. Root, editor of GLEANINGS. He jocosely says that it sort of inflated him, and that he may soon start a paper, to be called *Gleanings in Canadian Bee Culture*. But we think that, with proper care and sufficient time, he will recover.

It is a good thing for one to see himself as others may see him, and I am only sorry that I do not remember to have met that "twin" brother. If I did meet him, I was not aware that he had been taken for me or I for him. The next time I meet the gentleman I hope he will introduce himself as my twin brother. I am sure friend Heise doesn't need to feel flattered because of his likeness to my poor self. Many another in my shoes would do far better than I.

By the way, this is not the only instance of mistaken identity at the Buffalo convention. Two men, of about the same size and height, who attended, looked decidedly alike; and when the two sat near each other it was almost impossible to tell which from t'other. One was a quiet, genial, pleasant man; the other was always bobbing to his feet, and making himself notoriously disagreeable—always throwing out objections, and never harmonizing with the discussion. I said to the first-mentioned person, after I had learned to distinguish one from the other, "Why, you look almost exactly like —."

"I am not flattered," said he. "I have no sympathy with his ways of doing. Such men are always a bore to a convention, and a drag to good discussion."

HOW TO GROW A CROP OF PUMPKINS; VALUABLE SUGGESTIONS IN REGARD TO PREPARING THE GROUND FOR FARM CROPS IN GENERAL.

The picture we give of forty acres of pumpkins shows such a thrifty crop that we asked for particulars in regard to growing pumpkins for a canning-factory. The reply will be

FORTY ACRES OF PUMPKINS.

found below. For several years past, so little attention has been paid to growing pumpkins in our vicinity that the prices have ruled quite high. In fact, I have, during the past two or three months, paid 5 cts. apiece for every load that I have seen brought into our town. Where they are large and fine I have paid as much as 6, 7, and even 8 cts. each. These have all been sold for pie-making. In fact, for several years back we have been getting as much per pound for nice pumpkins as for watermelons. I suppose no great amount, of course, could be sold at these figures; but it is well for the market-gardener to grow enough to supply his customers. When I was

a boy the farmers used to be glad to get a cent apiece, little and big.

HOW THE "40 ACRES" WAS MANAGED.

Our land is very dry, and was not much affected by the heavy rains in August; but the drouth killed the vines four weeks ahead of time this fall, and, we believe, cut the crop 50 tons short. We harvested 554 tons from 37 acres. Thorough cultivation and plowing under green manure (rye, buckwheat, cow peas, crimson clover, etc.), we believe will bring good crops almost anywhere. We plowed under crimson clover last spring, and have another crop growing now.

We seed 20 pounds per acre, and cultivate in at last cultivation of crop, say about July 15th. Crimson clover and cow peas are our favorite manure crops. If the farmers in any county would pursue plowing under these crops for ten years we believe their county would be the banner one of the State. Every acre of cultivated crops should be sown with crimson clover.

If it is not a complete success every season, we believe it will pay fully 100 per cent on the investment.

We used some air-slacked lime, potash, and phosphoric acid on the clover, but this did not show any marked gain over where none was used, and we are not prepared to say that the benefit equaled the cost.

We believe in subsoil plowing at least once in five years, and oftener if there is a surplus of horses that can be used without hiring extra help. We run the subsoil plow about eight or nine inches below the bottom of the furrow turned by a common plow. It does not turn up the subsoil, but it is lifted up and dropped back in a mellow condition, breaking up the hard crust on top of which the common plow has run for years. This gives a mellow soil about 16 inches deep, which, with the green manure, will hold moisture like a sponge during a drouth, and let off surplus water when there is too much. Some claim land leaches its fertility if this subsoil is broken up, but this has not been our experience. In laying sewers, etc., where

we have dug trenches three to six feet deep, we find there is nearly double the growth over these trenches compared with the growth alongside of them where the ground is mellow only as deep as plowed. Our theory is, that, where the soil is mellow, the roots will follow after the fertility to the depth of several feet. The mellow soil acts as a catcher and absorber of fertility, while with the hard subsoil there is nothing to absorb and hold either moisture or fertility; and any getting through the hard crust below the plow is lost. The fine roots of plants can not get into the hard subsoil to use what little fertility there is. With a perfectly mellow subsoil we believe it impossible for fertility to get far enough away so that a vigorous crop of any kind will not find it. In proof of our ideas of green-manuring, etc., we submit the following crop figures:

On one field of about 12 acres of our poorest land we have grown a crop of pumpkins each season for the past three years. In 1895, 465 tons; 1896, 116 tons; 1897, 151 tons. Next spring we shall subsoil this piece and expect to get still better results. Of course, we grow special crops, pumpkins, tomatoes, etc., but the same laws of fertility, deep mellow soil, thorough cultivation, etc., we believe govern the growth of all crops.

#### IN REGARD TO COW PEAS.

If we can keep up the fertility of our soil with crimson clover we do not expect to use any more cow peas. When obliged to lose a cultivated crop we get three crops to plow under. Cultivate or harrow in rye on old ground in the fall; plow under in the spring; sow cow peas; plow under and sow rye in the fall, which we plow under the following spring, and plant the crop we wish to grow. Poor land can not remain poor with this treatment. H. A. CUMMINS.

Conneaut, Ohio, Nov. 29.

I wish to add emphasis to the remarks in regard to subsoil plowing. Almost every season we have one or more excessive rains; and even on our ground that is thoroughly underdrained we have had troubles with wash and from the soil getting so full of water that it settled right down like mud. I remember one spring, when we had prepared the ground up around the windmill with special pains and care. It was plowed a foot deep, and then worked up until it was soft all the way down. When a heavy rain came I stood by the window watching; and for a considerable time after the other ground was full, and the water running over the top and cutting gullies, this piece on the hill seemed to be still taking in and holding the whole freshet. Just as the shower wound up, however, I saw the ground had got all it could hold, clear down as far as our plow went. The whole piece was getting to be soft mushy mud. Finally it began to break away here and there, and my rich mellow soil, manure and all, began to start down toward the lower land, washing up valuable plants in places. The rain let up, however, before very much damage was done. Now, had this piece of ground been broken up with a subsoil plow as friend Cummins has advised, I think it would have taken up and held all the water. I know a good many have reported unfavorably in regard to subsoiling; but I think it must certainly answer two purposes when properly done. First, it prevents washing or letting the loose soil settle down again hard and compact. Secondly, it helps to hold the great mass of water, that comes during these excessive freshets, at a point where the roots of the crop can go down and reach it in time of drouth. I have tried subsoiling to some extent, and I feel just now very much like trying it again, especially for a crop of pumpkins next year, and I am pretty sure I can raise them for *considerably* less than a nickel apiece.

#### PRODUCING JUST SO MUCH AS YOUR MARKET DEMANDS, AND NO MORE.

When I first commenced market-gardening I had some sad experiences in producing large crops of perishable goods that could not be sold when they were ready to gather. I think I started out with about an acre of early peas. We filled our town, and then tried to sell more by putting the price away down, and finally sent them in wagons to neighboring towns, but got hardly enough to pay for the time of the man and team. I know some people do well in shipping these things to distant markets by rail; but what few experiments I have made in that line have turned out so badly that I became disgusted with that business. For instance, I made one shipment of Jersey Wakefield cabbage, extra nice. When I complained because the commission man made no returns or reply whatever, he said the cabbages sold for just about enough to pay the freight, and he could not see why there was any need of making any reply under the circumstances. Well, after that year I learned to plant just about as many peas as our market would take, say at from 20 to 40 cts. a peck, and the same way with parsnips. Once or twice we had so many we could hardly sell or give them away. After that I figured out just about how many rows I should plant the length of my creek-bottom ground, so they would all be sold by the time I wanted the ground for another purpose; and for several years I have been enabled to hit it about right on all these things that we can not gather and put away until somebody wants them.

But one thing has pleased me; and that is, to note that the demand is steadily increasing. Last year I sold from 50 to 75 bushels of parsnips at about \$1.50 per bushel, retail. The parsnips were nice, and given to the people fresh, digging them only as fast as they were wanted. Well, this season, for the first time, we have had a good demand for parsnips in the fall. We have been selling about a bushel a day for perhaps the past three or four weeks. To-day, Dec. 9, the weather is very warm and nice. There is no frost in the ground, and we have been digging our carrots and bringing into the cellar a fresh supply of parsnips. We made a mistake this year in not having carrots enough. A few years ago we used to have trouble to sell all of our crop, even at the low price of 25 cts. a bushel. This fall our first customer took almost our entire lot; and, by the way, how much money do you suppose one could get out of an acre of creek-bottom land, sown to carrots, at 25 cts. a bushel?

Shall I tell you how I harvest them? Well, we first plow a deep furrow as close to the roots as we can without cutting them. Now, if you manage just right, the next furrow will throw the carrots all out of the ground. Teach the boys to go right along walking in the furrow, and twist the tops off, leaving the tops down in the dirt. If you do not go with them they will pull the carrots out of the ground, tops and all, and then fuss to twist the top off, throwing it one way and the carrot another, whereas you will get along twice as fast if you leave the top right down in the

ground where it has been turned under by the plow. Just twist off the root and toss it into the basket. When the soil is just right, carrots can be grown so thickly that they almost crowd each other out of the ground. Horses, cattle, and almost all stock, are not only very fond of them, but a moderate use of carrots along with the grain is beneficial, both to horses and cattle.

#### APPLES.

The Department of Agriculture has just issued a catalog of fruits recommended for the United States. It is entitled Bulletin No. 6. About four pages are devoted to apples. On these four pages 259 kinds are described, besides 17 kinds of crabs. By a very ingenious table they give size, form, color, flavor, quality, season, use, and tell where the variety originated, as nearly as possible. The size is from 1 to 10; quality 1 to 10, 10 being the largest and 10 the best. I looked over it with very much interest to see how their rating would agree with my own. They rate the Baldwin in size as 7 to 8; quality 5 to 6. In our locality we should have put the quality a little higher. But perhaps we are not acquainted with all the new kinds. Belmont is put 9 in quality—next to the head. This would agree with me exactly; and Ben Davis—now, reader, where would *you* have put *Ben Davis*? They have it 4. I think I should have put it a little higher; but people generally here in the North would agree, perhaps, with them. Benoni is 7. I tried to think of the poorest apple I knew, and turned to Fallawater. They have it 10 in size but 4 in quality. When apples are scarce, and people can not get any other, or they are not acquainted with the Fallawater, they buy it very well. One great objection is, it is not good to cook. Fall Jentening is put 3 to 4; and I think that is about as low as they mark any thing in quality. Fall Pippin is 10 in size and 10 in quality. Whenever I think of the big apple-tree that Mrs. Root's father used to have right near the house, I make up my mind that 10 is about right, both for size and quality. Now, were I sure that Mrs. Root would never see this I think I would say I used to think farmer's daughter was 10 also (the very highest mark, you know). The Russian Gravenstein is marked 8 in size and 9 in quality. The Lady apple is 1 to 2 in size, 6 to 7 in quality. Maiden's Blush is 5 to 6 in size, 4 to 6 in quality. I should have put the quality a little higher. Newtown Spitzenburg is 10 in quality, so is Summer Pearmain; Winesap is 6 to 7. Yellow Newtown, or rather, Albemarle Pippin, is marked 10.

I presume this bulletin will be mailed to any one free on application. It is put out by the American Pomological Society, and is revised by T. T. Lyon. I rejoice to see such a bulletin, because it is *authority* on matters that have been so mixed up. By its aid, almost any apple-grower can decide whether he has got the names of his apples correct or not. Judges at fairs can also decide pretty correctly as to whether the apples on exhibition are correctly named. As the bulletin discusses in

the same way almost every other fruit we grow, north or south, it will certainly prove to be of great value. Yesterday a carload of apples came to Medina. The price was about \$3.00 per barrel, wholesale. I told the owner I would take ten barrels if he could furnish them all different. I think they came from Missouri. There are several new kinds I did not find in the list mentioned, and among them are some equal to any I ever saw or tasted. I would especially mention the Wabash Sweet and Stark.

---

## OUR HOMES.

---

Abstain from all appearance of evil.—I. THES. 5:22.

The text above was brought to mind just a few minutes ago. A letter was handed to me from a good friend whose feelings had been very much wounded, and he was greatly stirred up by the way we had treated him. For a time nobody could imagine what it was that made him feel so hurt. He alluded to a letter written to him on the 18th of November; but the clerks all stoutly declared that no one had written to him a word at that time. After a good deal of time spent in investigation I found a *printed* letter had been sent him from the subscription department. He had had hard times, and was in arrears; but, notwithstanding, he had been sending us a dollar about once a year pretty regularly of late. This money had been carried to the ledger, and credited on his *old* account; and in this way his subscription account showed that he was in arrears two or three years. I found, in the middle of the printed letter, this:

Up to date we have heard nothing from you in regard to the letter we sent you in reference to your subscription, and have therefore dropped your name from our subscription list, leaving amount due us on arrears as per statement below.

Now, the statement in the printed letter was not true, for he sent us a dollar a year ago, and another dollar recently, and he, not *noticing* that the letter was a printed one, and not written on a typewriter, thought we were ignoring the amounts he had been sending us. I hardly need tell you that, since typewriters have come in vogue, it has become quite customary for business men to have letters printed so as to look so much like a letter written on a typewriter that people are deceived. They think a business firm has taken the trouble to write them a personal letter, when it is only a printed one, such as is sent out to thousands. The reason for this is that most people will pay more attention to a personal letter than to a printed circular.

But I protest against this whole business, and have been protesting for years past. I have refused to subscribe to mission work, and have thrown the letters into the wastebasket, because it was very skillfully managed for the express purpose of deceiving or deluding the person who received it.

May I take the liberty of changing just a little the beautiful text at the head of this? I would say, "Abstain from all appearance of

deception." It is frequently urged that some kinds of deception are harmless and innocent. We are told that there is "not one person in ten but knows at a glance that it is a printed letter." If that is so, then why take so much trouble? I do not believe it is best or wise to deceive even a child—not even the baby; and it surely is not right to deceive elderly people who may be childish. Neither is it right or wise, in my opinion, to deceive the middle-aged. If you want to send a printed circular, that can be sent out by the thousands, make it plain to every one, young and old, that it is a printed circular and nothing else. I believe this course would be the most profitable in the end, in business matters; and I am sure that, in Christian work—especially in mission work—we can not be too *sincere* and *transparent* in our acts and words. It may be that the advertisers who pay so much money to our periodicals gain riches by making deception one of the fine arts; but I am sure they do not secure clear consciences and a kind of happiness that is worth more than *all the gold in Klondyke*.

*Dear Mr. Root:*—Won't you please send me the copy of GLEANINGS in which you told us how you returned thanks at the table? I am here visiting a beloved sister. We used to read GLEANINGS together. It was where you told almost word for word how you prayed at the table. I have read your sermons for ten years, and am back here telling my sisters about them. The girls are working to establish family altars in their own homes. I told them there was lots of help in your paper, and about that particular one in regard to returning thanks. I can not remember the date, but it was some time in the last four years. When I came to my sister's I tore out a lot of your sermons and brought them home to them, but I haven't the most desirable ones. I took the magazine just for the sermons during the last six years. I have often wondered what religious papers you people read back there that you could throw out so many good hints. Or was it God and the holy Bible and prayer alone? I don't think that was all of it. I believe you have earthly helpers besides the help our Father in heaven has given you. Am I guessing right? MRS. M. A. TRAVIS.  
Robinson, Brown Co., Kan., Nov. 15.

Some of the friends may be a little surprised that I should use the above letter with the exceedingly kind and encouraging words, when it evidently was not intended for print. Another thing, as a rule such words of commendation are best kept to one's self, as the writer evidently intended. But along with these kind words comes a most tender and pathetic plea for the old-time fashion of asking a blessing at the table, and having family worship in our homes. Dear friends, this is my last Home talk for the year 1897; and very likely a good many will discontinue, and to those it may be the last talk I shall ever give them. The thought has been coming to me, "What is the most important message I can send to the homes and home people who read GLEANINGS?" It would be something right in line with this letter in my opinion. Do not let the world with its cares—do not let the changed order of things induce you to forget Bible-reading and daily prayer. Do not let electric railways, electric lights, modern machinery, and modern ways of doing things crowd out the word of God; and do not, I beseech you, let *any thing* that this world may offer, crowd in so as to make your relations to

the great Father above any more distant than they have been. May it rather be, in the language of our old hymn,

"Nearer, my God, to thee."

The little prayer that I suggested for use before partaking of our daily food is found in GLEANINGS for Nov. 15, 1895, page 868. It is as follows:

"O Lord, we thank thee for this pleasant and happy home. We thank thee for these our dear children. We thank thee for health and strength, and for good appetites, and for this our daily food. May it strengthen us that we may be helpful, one to another, and that we may be self-sacrificing; that we may have grace to use our strength so that selfish feelings shall be put down, together with all that is evil; and may we uphold all that is good and noble and pure, for the sake of the dear Master, our Lord and Savior Christ Jesus. Amen.

Now, dear friends, I did not intend that that prayer should be copied or used *every day*, by any means. There is only one prayer in the world that we can use in place of something of our own wording, and that is the prayer given us by the dear Savior himself when he was here on earth. The reason why I outlined the one above was to suggest some of the things we should remember to thank God for. Every man, woman, or child who has a home ought to thank God daily for that home, humble though it may be. *Any* home is better than *no* home. Some of you may think I do not know all about what I am saying; but I think I do know pretty well all the trials and difficulties that homes present.

Again, we should thank God for our parents, children, brothers, and sisters. We should remember to thank him for good health, strength and good appetites. The advertisements in newspapers constantly remind us how few there are who enjoy really good health, and can eat with impunity what is generally set before us.

Again, we need God's grace and wisdom to make a good use of strength. We need to be saved from the sin of ingratitude, from evil thoughts, and from all suggestions of the tempter; and in our daily worship we should remember the events, the anxiety, the longings, that belong peculiarly to each day. No two days are alike. As a *rule* I would try to have no two prayers alike—not even asking a blessing at the table. This is pretty hard, I know, when we think of the number of times we are called upon to give thanks in a year. Very often when I sit down to my meals, especially after I have been delayed, and prevented from being on time, I am faint and exhausted; and sometimes it is about all I can do to call up grace enough to repeat words that I have used perhaps thousands of times before. Now, please do not misunderstand me, dear friends of the Home Papers. The prayer that is repeated until it sounds almost stereotyped is better than *no* prayer at all—a thousand times better; but if we use the same words over and over, we should have to be more than human if they did not in time get to be meaningless.

It happens to be my privilege to be one of the volunteer observers on the Weather Bureau, and I enjoy studying the weather with all its varied features every day in the year.

There is not a single day but I find something to thank God for in the weather. I do not believe, dear friends, this is extravagance. T. B. Terry once said he could always find reasons to be happy when it rained, and he could also find other reasons for being happy when it did *not* rain. That is the right spirit. Let us be so loyal to our Maker, our heavenly Father, our great, good, and wise *Friend*, that we shall never be tempted to be rebellious and cross about the things we can not help, and which are unquestionably in his domain. The courts of law, you know, specify that a man is not held responsible for certain things they term "the acts of God." Now, it seems to me it is an excellent thing to remember the weather in our daily petitions, and in giving thanks. When the community in general needs rain, let us ask God for the rain that is needed, day after day, until it comes. When it comes so as to cause disaster, as it did down in the Mississippi Valley last spring, let us unite in asking him day by day to withhold the rain till it ceases; and let us, in our daily petitions, beware of confining our thoughts to our *own* little home or neighborhood. Every family reads the papers enough nowadays to know of the suffering in different parts of the world. Let us pray for these neighbors, while we remember the great Father above always; let us also always remember the chief officers of our government. Do not forget to pray for the President of the United States, no matter what political party you or he may represent; and do not forget to be loyal afterward in your talk during the day, to be consistent with your daily prayer. Be frank and free to tell *God* all your troubles. In your closet alone, remember your children, calling them by name, and the same with your friends and neighbors; and by all means remember the editor of your favorite home paper.

And this brings me to the concluding words in the question at the end of the kind letter at the head of this talk. May I address her in my answer? Dear sister, I believe my daily Bible-reading and prayer have much to do with that portion of God's Holy Spirit which you and other friends give me the credit of having received; and I know full well that there are many praying for me that I may not make a mistake nor go amiss nor be led away by *any thing*. I have been helped by the thought that many are praying for me. I have been greatly helped, also, by such letters as the one I have given. They have been coming constantly ever since this, my lifework, was commenced.

Once more, dear sister, it has been my good fortune to have kind Christian friends and helpers here at home. The dear old mother who watched my wayward steps in infancy, and again through middle life, when I was for a time led away, is near me still, although she is now 85 years of age. Many of the helpful thoughts I have given you perhaps belong to the dear wife; and now as my sons and daughters have come to maturity it gives me more joy than I can express to see them give me helpful suggestions and encouraging words

May God be praised for all these things I have mentioned.\*

Now, please take me as I mean. I do not think I mean to boast when I suggest that, had I pushed on in the direction I started something like thirty years ago, there would have been no Bible, no prayer, no Christian home, and very likely no home at all, for me. In fact, I very much doubt whether I should be living at all to speak these helpful words had it not been for the saving power of the religion of Christ Jesus. I remember yet very well how these words will strike many of you. I know it is a little unusual to speak of sacred and holy things as I do in connection with matters of every-day life; and it is only because I am anxious for your best welfare that I do so. During the past year we have discussed the matter of medicines and physicians. We have discussed science and modern inventions; we have again and again together reached the point where man's skill and wisdom end. We have seen together, all of us (I am glad to say all of us) that there is a great universe where God reigns. He made us, he placed us here. Is it not our right and privilege as well as our duty to come to him in a loyal, honest, manly way, with all our wants and troubles as well as with all our joys?

As I grow older I believe I am changing somewhat. I used to be anxious to build up trade. Yes, I am anxious now to increase the circulation of this journal; but God knows I speak truly when I say I am *more* anxious that you should make God's holy word your guide and counsellor than that you should subscribe for GLEANINGS. I am weak and human; but God is infinite. I shall soon pass away and be forgotten; but Christ Jesus will stand forevermore. If your thoughts are on *him*, and if to him you intrust the care and keeping of your children, they will not be likely to go astray. When the writer of that letter mentioned her sisters who are working to establish family altars in their own homes, it stirred my heart more than any thing else I have seen or read for a long while. I said to myself, "May God bless the dear women! They do not know—they never can know—the outcome of bringing up just one little family and household in the fear of the Lord."

And let me close the talk for the year by saying this to each and all: No words can describe, no tongue can tell, the good that may come to future generations, clear down through the ages, by establishing to-day in your own home some form of family worship and daily recognition of God, the loving Father; and this, dear reader, is the message your old friend is sending to you and your home, the last one of the year 1897.

\* In regard to religious helps, I read carefully and pretty thoroughly the *Chicago Advance*, *Sunday School Times*, and the *Golden Rule*. These papers are my Sunday reading. I also like to read pretty much all of the books in our Sunday-school library, so that I may know what our children are reading. On week days I read almost all of our agricultural papers, or at least glance over them. Some of these, as I have told you, are taking a strong stand for godliness and for righteousness. Let us stand by them in their efforts for the good of humanity.

#### ON THE WHEEL.

All through the month of November I was planning a big long wheelride; but in our locality it rained almost every day, and the days it did not rain it was muddy. But I kept up my courage, and kept telling about the wheelride I was going to take, every morning, at breakfast, until the children laughingly begged me not to talk about it any more, because, if I did, it would be sure to rain. But when the sun came out bright and clear on the morning of Dec. 10 I caught fresh enthusiasm. Of course, the roads were not very good, but there was a warm wind from the south. I took the train to a station distant about a mile from a brick pavement that runs into Cleveland. There were a good many jokes about my getting over that mile without getting the shine off my boots; but, to my agreeable surprise, I found it very nice wheeling indeed.

At one place where they were making some repairs in the road one of the men said, jokingly, "If he can get down that bank, he is an old hand at the business, sure." But I rode down it without a bit of trouble. Although there were great lumps of dirt, so that it looked as if it might bother a horse to get through, it was all the way down hill. By skillful guiding and twisting and pushing ahead and holding back on the pedals I got through what looked like very formidable difficulties. I kept my seat, and was over the break in a trice, and when I got on that brick pavement, with the strong wind behind me—but, didn't I just spin? This "good road" is about fourteen miles long, and the only thing that marred my pleasure was the number of teams drawing heavy loads into the city all along the road. They did not mar my pleasure very much, after all, for the kind and courteous way in which they gave me room to pass fully compensated for what little hindrance I met. Not one driver in all the fourteen miles was in the least unfriendly. Several who had loads said that, if I had rung my bell a little sooner, they would have turned out for me willingly.

There is a pleasant moral right here. People are beginning to recognize the value of wheels, and the place they are to take in the future. I did not use my bell much, because that might have seemed to many people like saying, "Get out of my way there." Instead of ringing the bell I said, after starting to ride around the team, "Will you please swing your horses over just a little?" or, "Will you please slack up just a little until I get ahead?" After I got on the bricks again I always said, "I am very much obliged to you indeed." Altogether I had a most enjoyable ride in the middle of December. I returned home on the train.

## Health Notes.

### CONTROLLING DISEASE BY THE FOOD WE EAT.

Before giving the following extract from the *L. A. W. Bulletin*, perhaps I should explain that correspondents in that journal give their *L. A. W. number* instead of their name. I have been persuaded to give this communication a place because I am sure it strikes on a great truth. Not only may rheumatism be at least largely controlled by the diet, but I am strongly impressed that there is scarcely a disease that torments humanity that does not come a good deal under the same head. It is improper food or too much food that produces disease; and the only rational cure is to go back to where the mischief started. You will notice that our friend indorses the meat diet (the Salisbury lean-meat treatment) by saying he eats all the meat he wants, at least once a day.

The letter from No. 130,538, on reduction of weight by riding, is very interesting, and no doubt the drinking of large quantities of water under the condition of profuse perspiration will, if the water be pure, act to reduce the tendency to rheumatism. He admits, however, that his rheumatism is again returning. It is strange, but too true, that in this age of progress and advanced civilization, the simple facts concerning that most painful and prevalent malady, rheumatism, are not better understood.

Whether it is that doctors do not care to consider preventive means, or that people are not willing to deny themselves any thing at all, certain it is that rheumatism can be almost entirely controlled by a proper selection of food. This may come under the head of diet, but is not synonymous with starvation, as commonly assumed. Perfect digestion and assimilation of the food eaten means health, strength, and vitality: but how many of us possess it? I know hundreds who are suffering from stomach troubles, but only one man who realizes the fact. They invariably ascribe it to other causes—usually overwork. It is overwork, but not of the mental faculties, as they prefer to think. If No. 130,538 would try abstaining from sugar, grease, and starchy food—particularly fried potatoes—pastry, and fried cakes with syrup, he will find his weight decrease, and all his faculties improve in a very short time. I suffered for years for want of this knowledge, but finally obtained it upon the highest medical authority, and now enjoy better health than I ever remember, and I should like to see others equally benefited. I eat meat once a day, and all I want of it. The other two meals consist principally of corn or graham bread, and fruit stewed without sugar, or fresh fruit, than which there is no better food. The alkaloids contained in coffee upset the stomach, but that is nothing to the stomach troubles caused by the medicines commonly used for the so-called cure for rheumatism, all of which can be avoided by not eating or drinking the stuff which is the cause of the trouble.

### DOSING YOURSELF WITH DRUGS WITHOUT THE ADVICE OF A PHYSICIAN.

As an illustration of the danger of this work, the following incident has just come under my notice. A person was feeling poorly; and after trying several remedies, and being "nothing better, but rather grew worse," as Mark puts it, in regard to a certain woman, he consulted an able physician. I happened to be present. After looking him over a little the doctor said:

"Have you been taking quinine to-day?"

"Yes, sir."

"How much, and how long ago?"

"I took four grains about half an hour ago."

"Is that all you have taken to-day?"

"No, I took four grains two hours before the last dose."

"My dear sir, your pulse is up to 120, while 72 is what it should be. Quinine is the very thing you ought not to touch. At the rate your heart is pounding away just now it will pound you to pieces soon. Your short, quick breath should have admonished you not to touch stimulants."

Now, this is not an unusual occurrence by any means. We have all had experience in seeing people tinker with machinery or complicated apparatus (when they knew *nothing* about the thing), in the vain hope that they might by some blunder hit the right "cog-wheel." If a machine is spoiled through mistaken kindness it is of comparatively small account; but if you think I am *wrong* when I tell you to let drugs and medicines alone, ask your family physician, in whom you have confidence, what *he* thinks about it. If somebody offers you medicine, "free of charge," do not touch it. Remember the man I told you of who planted tomato-seed because he got it free from the Seed Department. He could have purchased seed that he knew was all right, and just what he wanted, for *five cents*; but he planted the other kind in a hot-bed, got them out in his garden before anybody else, then harvested a great crop of crooked, scraggly, late tomatoes that nobody would take as a gift. Now, the medicine you are offered free of charge may be even a worse speculation. These medicines given free usually contain morphine, cocaine, chloral, or some similar drug. Of course, the patient "feels better," and wants some more medicine. But it costs \$2.00 a bottle, or three bottles for \$5.00. May the Lord be praised, a law has just been passed making it an offense either to sell or give away medicines containing these terrible poisons. The druggists and patent-medicine men are beginning to writhe and squirm already, because it threatens to kill their business—at least a good share of it. Why in the world this new law does not include cigarettes, I am unable to say; but I am on the "war-path" in regard to the matter.

#### LIGHT FOR DARK PLACES.

I tried to tell you in our last issue my convictions in regard to what was coming in the way of electric lighting. Below is something I found on a scrap of paper:

Electric-light meters, with penny-in-the-slot attachments, promise to become popular in some places. A London company supplies current for an eight-candle-power incandescent light six hours for a penny dropped into the box, and allows the customer to take his six hours' light at once or in small daily installments, as he chooses to turn his switch.

There, friends, do you see it? By the aid of a storage-battery, with electric light attached, an apparatus can be left in every home, so that people of moderate means may have the benefits of this beautiful light by simply dropping a penny or a nickel into the slot. No expensive man will be needed to keep the books, and there can be no complaints about unfair dealing. You put your coin into the machine,

and you get your number of hours of light, to be used as you want it, by pressing a button. When the storage battery is exhausted, somebody comes right to your door and replaces it with a fresh machine. I think the price can be made so low that almost every home may be thus supplied. Of course, the dynamo to charge the batteries must be somewhere near, and my belief is that the wind that blows so much of the time over our heads (and against them), especially at the season of the year when we have short days and *long nights*, will do this storing of electricity. All that is needed is an inventive genius to make the thing practicable.

#### THE NEW ACETYLENE LIGHT.

There have been so many inquiries in regard to this that I have decided to give in full the following letter from friend Long, to whom I have referred before—see page 718.

*Dear Friend*.—I notice in GLEANINGS for Nov. 15th several articles on acetylene gas, which may be confusing to the average reader. The article referred to in the *Cosmopolitan* is somewhat misleading, if not carefully studied, as, in practice, acetylene is used in a pure state, unmixed with air, and with less than three ounces of pressure, under which conditions it is absolutely non-explosive.

The dangerous qualities of acetylene as now used have been much exaggerated. In many respects it is much safer than kerosene, city gas, or electricity. City gas is nearly as explosive as acetylene, still, with the great amount continually used, but few casualties occur, while acetylene has these important advantages—that but one-tenth or less in a bulk is used for the same light, and the strong odor of the unburned gas will always cause its presence to be known long before enough could escape to be ignitable, which fact Prof. Jacobus seems to have overlooked.

Kerosene is more dangerous than acetylene, but we have all become so accustomed to the use of kerosene that its dangerous properties are not thought of.

With properly constructed generators, acetylene is doubtless the safest illuminant we have; and the principal reason why it is thought by some to be dangerous is mentioned by Prof. Jacobus, of its having been first used in a liquid form under a pressure frequently as high as 1000 pounds to the square inch, in which form it is liable to cause mishaps.

We have been using it constantly for over a year, and feel much safer with it than in using kerosene lamps, as, with our generator, the acetylene is in a pure state, unmixed with air, and it is impossible to have more than three ounces of pressure to the square inch, under which conditions it *think* even Prof. Jacobus would admit its superior safety.

There is a plain discrepancy between Prof. Jacobus' figures as given in the *Cosmopolitan*; but, even by taking his figures, acetylene at \$97.50 per ton for carbide would be as cheap as gas with ordinary burners in New York city; less than one-third of the cost of electricity in New York, and much less than half the cost of gas in many places.

According to careful tests by expert chemists, carbide at \$80.00 per ton costs about the same as kerosene at 8 cts. per gallon or city gas at 45 cts. per 1000 feet, for the same amount of light.

As our generator requires absolutely no attention whatever for a number of weeks or even months after refilling, we can imagine nothing safer, more convenient, or cheaper than acetylene, especially for country homes; and when the quality of the light is considered in connection with its general superiority it certainly seems destined to supplant shortly other means of lighting, not only for domestic use but also for nearly every other purpose. At the present time it is being used in many homes, with the greatest of satisfaction.

Could you give me the names and dates of the periodicals to which you refer as showing acetylene to be unfitted for domestic use? I wish to keep thoroughly informed along this line. I hope to send you a portable lamp which seems to be doing nicely, in a few days. An authority I have before me states that the number of candle-power hours for \$1.00 would be—in-

candescant electric light, 1600; illuminating gas, 2500; acetylene, 6700. D. N. LONG.  
La Salle, N. Y., Dec. 3.

Perhaps I should inform our readers that Mr. Long is an enthusiast on this new discovery, and he may, as would be very natural, overestimate in some of his statements. I believe him to be a good and reliable man. But our readers will have to take their chances if they invest in the new light, as you see I have not yet had an opportunity for testing the lamps. I notice this, however—acetylene seems to be taking the lead in furnishing a lamp for bicycles. My impression is, it gives a stronger light than even electricity, for lamps for this purpose; but it must be lighted with a match. In view of the disastrous fires we are having all the while, I object to matches and fire in any form where they can be avoided. With the electric lamps, we have only to press the button to make it go. It can not set fire to any thing. Yes, I object to matches and fire, even when they are used to light a pipe or cigar. But may be I am peculiar.

THE "MISSING-LETTER" FAKE.

On page 826 we put in a protest in regard to this sort of thing. It is the advertisement that you see in the papers, where a prize is offered to any one who will supply the missing letters to make out a word. The puzzle is so easy and simple that a person not really smart would guess it all at once. The swindle is in persuading ignorant people that they are *unusually smart*. When they send in their answer a reply is made that they have drawn a prize of a fifty-dollar watch and chain. But in order to get this prize they must send \$5.00 for a five-years' subscription to some journal, etc. I need not detail the rest of the ingenious evasions and subterfuges to rob credulous people of their money. In one of the dailies I notice the following:

The postal authorities have decided that all the "missing-letter" contests, where prizes are offered, are lotteries, and newspapers containing such advertisements must be excluded from the mails.

One wonderful thing in regard to this whole disgraceful scheme is that it has been pushed largely by religious periodicals. May God help us to better defend the sacred name of Christ Jesus—the name the religious press should especially hold up and protect.

#### AUTOMATIC SAW-GUMMER.

We have had for a number of years a Covell automatic saw-gummer for sharpening small circular saws, both rip and cut-off. Having recently put in a larger band resaw we also purchased a combined automatic gummer, which will take both band and circular saws. This renders the first gummer of no use to us. We paid \$150 for it new, and will sell it now for \$30, crated, and free on board cars here. Shall be pleased to give further particulars to any one interested.

#### HONEY MARKET.

We have on hand all grades of comb honey at prices mentioned in Dec. 1st GLEANINGS. We can make a special low price on several hundred pounds of No. 1 white, in 24-lb. cases, to any one who can use somewhat irregular combs. These are not bad, but hardly what we like to send out as regular A No. 1. If interested, write us in regard to the lot. Our A No. 1 and fancy amber grades are especially desirable. These are not dark, but are nearly equal to white honey, and the finish and style of putting up is the very best.

The price of extracted remains unchanged. We are still open for offers on choice clover extracted honey; have secured some, but want to get track of more in 40-b cans, if to be had in that shape, at a price which we can pay.

#### FENCES, OR CLEATED SEPARATORS.

We are receiving a great many inquiries, orders for samples, and some good-sized orders for the new fences. We are having some new illustrations made showing the different ways of using these fences, which we hoped to print in this issue; but our engravers were so crowded we could not get them in time. We will show them in the Jan. 1st issue. From many of the letters and orders received, it is evident that the use of these fences is not well understood, or more care would be taken to state just how you expect to use them. We gave a warning in regard to this a month ago; but as the special notice containing this warning was over among the advertising pages, many did not see it. Even Dr. Miller, the "Straw" man, overlooked it. We would advise you to look it up and read it. The regular fence to be used with plain section-holders and  $4\frac{1}{2}$ -inch sections is 17 $\frac{1}{2}$  inches long, and has end standards  $4\frac{1}{2}$  inches long,  $\frac{1}{2}$  inch thick, and  $\frac{1}{2}$  inch wide, and will be known as the H fence. Price \$1.00 per 100; \$9.00 per 1000. The same fence, with end standard  $4\frac{1}{2}$  long and  $\frac{3}{8}$  wide, making it 17 $\frac{1}{2}$  inches long, is used with  $4\frac{1}{2}$  sections on T tins as we now make them, with  $\frac{1}{4}$ -inch upright. To use with old T tins as formerly made, they will need to be grooved across the bottom edge  $\frac{1}{4}$  inch deep to let them down to place over the T tin. These fences without the cross-grooves will be known as K fences, and the price will be the same as H fences. To use in connection with the old-style slotted section-holder with the plain sections requires a fence with the slats projecting beyond the end standards. The end standards, like the intermediate ones, are, on this style fence, in two parts attached to the slats, and are  $\frac{1}{2}$  inch wide by  $4\frac{1}{2}$  inches long, projecting below  $\frac{1}{4}$  inch, and even on top. The full length of this fence is 18 inches; but the distance between the outside edges of end standards on the two opposite ends is just 17 inches, so that these standards come inside of the section-holder ends against the edge of the plain section. The fence is supported by the end standards resting on the section-holder bottom just inside the section-holder end, and the slats projecting beyond the end standards come between the section-holder ends. See illustration in Trade Notes, this issue, which is not correct, because it does not show the slats projecting beyond the end standards. This fence will be called the J fence, and will be sold at \$1.20 per 100; \$10.00 per 1000.

Here, then, are three fences, all different, and yet all for use with the  $4\frac{1}{2}$ -inch plain section. There are other kinds of supers and fixtures for the  $4\frac{1}{2}$ -inch sections, which will require fences still different from those described. If you have taken in all the foregoing you begin to perceive the necessity of being very particular to designate just how your fences are to be used, when you order, if you would be sure to get

what you want. Now, you can cut a K fence from an H fence, but neither will make a J fence; and you can not easily make either out of a J fence. We have just received an order for 2000 plain sections and 300 fences "to fit the ordinary Dov. super which section-holders have been used in." As no plain section-holders are ordered, it is not quite clear whether the party intends to make these or to use the old slotted ones; and you see it makes a big difference when we fill the order. I mention this case only because here is where the greatest difficulty is going to be, and where the greatest care will be needed in making your orders.

There are other fences which we will regularly furnish. For instance, the I fence for the Ideal super, with the  $3\frac{3}{4} \times 1\frac{1}{2}$  plain sections. This arrangement will be more fully described and illustrated in next issue. This fence is 18 $\frac{1}{2}$  inches long, with end standards  $5\frac{1}{2}$  inches long, and  $\frac{3}{8}$  inch wide. Seven of these, with six straight slats,  $3\frac{3}{4} \times 1\frac{1}{2} \times 18\frac{1}{2}$ , and 30 sections of above size just fit into a deep super, 8-frame size, and the sections hold just a pound of honey. Notice that you get 30 instead of 24 into an 8-frame super. The fence for the Ideal super will be the I fence, and the price will be \$1.25 per 100; \$11.00 per 1000. Then there are the fences, both single and double cleated, for the Dana's hive, with 4x5 sections, at \$1.50 per 100, \$13.00 per 1000. Another point of importance to make a note of is that, in each super, we use one more fence than we do section-holder or rows of sections. That is, the fence acts as a follower, and one is used on each side of the super. This serves a double purpose. It avoids putting cleats on the super as well as secures the advantage of the Pettit perforated and cleated follower which has been strongly recommended to secure as well-filled sections on the outside as in the center. It also does away with the follower-board. In the plain no-bee-way section, the standard width for  $4\frac{1}{2}$  square and the  $3\frac{3}{4} \times 5$  will be  $1\frac{1}{2}$  inches. This width, with the fences having cleats  $\frac{1}{4}$  inch thick, will hold the same amount of honey as the regular  $1\frac{1}{2}$ . If, therefore, you do not specify the width we will send  $1\frac{1}{2}$  inch. The width to correspond with the regular  $1\frac{1}{2}$  or 7-to-foot will be  $1\frac{1}{2}$  plain. In figuring out what width of plain section you wish to order to use in connection with the fences, and to hold the same amount of honey as the regular slotted section, you have simply to deduct from the width of the regular slotted section the thickness of two cleats, which is  $\frac{1}{2}$  exact, or  $\frac{1}{8}$  full. The whole fence is  $\frac{1}{2}$  inch thick, or  $\frac{1}{8}$  scant.

We have just printed on our new press 120,000 seed catalogs for A. T. Cook, Hyde Park, N. Y. We notice on the first page, which, by the way, is very handsomely gotten up, the following:

"I have been for twenty years in the seed business, and I do not know that I have a single dissatisfied customer."

Now, then, friends, if friend Cook has made a mistake in the above, you can call him to account.

#### CONVENTION NOTICE.

The annual meeting of the California State Beekeepers' Association will be held at Los Angeles, on Monday, Jan. 10, 1898, commencing at 2 P.M.

The California Bee-keepers' Exchange will meet in annual session at Los Angeles, on Tuesday, Jan. 11, at 2 P.M. A full attendance of members is desired. Mr. Thos. Wm. Cowan, editor of the *British Bee Journal*, will be present. The attendance of Thomas G. Newman is also promised. A. J. COOK, Pres.

J. H. MARTIN, Sec.

#### COLORADO APIARISTS, TAKE NOTICE.

The Colorado State Beekeepers' Association will hold its annual convention in the State Capitol building, Denver, Jan. 17, 1898. Let every apiarist in the State, who can, be at that meeting. Whether you can be at the meeting or not, write to me just as soon as you read this. First, I want your name and address, very plainly written. It is very likely that the association will have something to communicate to you that will be to your and others' interests, so we want your name and address sure. With the address tell me what topics you want discussed at the meeting, or any other business you want transacted. Any others—persons or associations—having business with this association will please communicate with our State Secretary, Mr. Frank Rauchfuss, Elyra, Col., or with myself.

R. C. ATKIN,  
Pres. Col. State Beekeepers' Association,  
Loveland, Col.

# Gleanings in Bee Culture

## AND American Agriculturist.

Weekly.

**BOTH ONE YEAR ONLY \$1.25.**

By special arrangement with the publishers, we are enabled to offer the American Agriculturist in combination with GLEANINGS IN BEE CULTURE at the unparalleled low rate of \$1.25 for both papers one year. The American Agriculturist is published in five editions. The N. E. Homestead, the Eastern, Middle, and Southern editions of American Agriculturist, and the Orange Judd Farmer. Each contains matter relating to its own locality, as well as the latest and most accurate market reports for the country in general. It has departments relating to all branches of farming, articles written by the most practical and successful farmers, supplemented with illustrations by able artists. Short stories, fashions, fancy work, cooking, young folks' page, etc., combine to make a magazine of as much value as most of the special family papers.

A sample copy will be mailed FREE by addressing AMERICAN AGRICULTURIST, Columbus, O., or New York, N. Y.

TAKEN separately these two papers cost \$2.00, consequently every subscriber under this offer will get

**\$2.00 IN VALUE FOR \$1.25.**

**Premium Books.** For 10 cents extra, as postage, you can have your choice of any of the following standard books FREE: "Profits in Poultry," "Farm Appliances," or "Farmer's Almanac" (ready December 15). Send your subscriptions direct to

THE A. I. ROOT CO., Medina, Ohio.

## Two Papers for the Price of One.

The **Farm Journal**, of Philadelphia, a monthly agricultural journal of 16 pages, sent **One Year Free** for one subscription to **Gleanings**, with \$1.00, paid in advance, either new or renewal. In the case of a renewal, all arrears, if any, must be paid in addition to one year in advance.

The **Farm Journal** is now in its 20th volume, and takes the lead among all the *low-priced* agricultural journals of this country and of the world. It gives no chromos, puffs no swindles, inserts no humbug advertisements, lets other folks praise it, and makes good to subscribers any loss by advertisers who prove to be swindlers. The editor was born on a farm and reared at the plow-handles, and the contributors are practical men and women.

The regular price of this excellent journal is 50 cents a year, and it is well worth it; but by special contract with the **Farm Journal** we are enabled to make the above very liberal offers.

THE A. I. ROOT CO., Medina, Ohio.

## A Bargain!

**Only \$1.50.** We have made arrangements to furnish **THE OHIO FARMER**, of Cleveland, Ohio, and **GLEANINGS IN BEE CULTURE**, both papers, for only \$1.50.

The **Ohio Farmer** is well known as one of the very best, largest, and among the leading agricultural papers of America. A 20-page, 80-column paper EVERY WEEK in the year; employs THE VERY BEST WRITERS that money can procure; a strong, fearless defender of the agricultural interests of this country, and CLEAN in both reading and advertising columns. IT HELPS MAKE THE FARM PAY.

THE A. I. ROOT CO., Medina, Ohio.
